---

AN Encyclopædia of any of the fine arts has, from its nature, considerable advantage over one which relates to the sciences generally. In the latter, the continual additions made to the common stock of knowledge frequently effect such a complete revolution in their bases and superstructure, that the established doctrines of centuries may be swept away by the discoveries of a single day. The arts, on the other hand, are founded upon principles unsusceptible of change. Fashion may, indeed,—nay, often does,—change the prevailing taste of the day, but first principles remain the same and as, in a cycle, the planets, after a period of wandering in the heavens, return to the places which they occupied ages before, so the arts, after seasons of extravaganza and bizzaria, a recurrence of the same taste is equally common.

It is unfortunate for the productions of the arts that the majority of those who are constituted their judges are liable to be misled for the task, either by education or habits; but on this, as it has been the complaint of every age, it is perhaps useless to dwell. This may be said, that before any one can with propriety assume the name of artist, he must have passed through some such course as is prescribed by the rules of the art; but its author has been to impart to the student the principles for the exercise of his profession; but an encyclopædia serve to form, guide, or correct, the taste of the amateur, the author will not consider that he has laboured in vain.

An encyclopædia is necessarily a limited arena for the exhibition of an author's power; for although every subject in the department of which it treats must be noticed, none can be discussed so extensively as in a separate work. An attempt to produce a *Complete Body of Architecture* the author believes to be entirely original. In his celebrated work, *L'Art de Batir*, Rondelet has embodied all that relates to the construction of buildings. Durand, too, (*Leçons et Précis d'Architecture*,) has published some admirable rules on composition and on the graphic portion of the art. Lebrun (*Théorie d'Architecture*) has treated on the philosophy of the equilibrium, if it may be so called, of the orders. The *Encyclopédie Méthodique* contains, under various heads, some invaluable detached essays, many of which, however, suffer from want of the illustrative plates which were originally projected as an appendage to them. All these, with others in the French language, might, indeed, be formed into a valuable text-book for the architect; but no such attempt has hitherto been made. Neither

in Germany nor in Italy has any complete work of the kind appeared. In the English, as in other languages, there are doubtless several valuable treatises on different branches of the art, though not to the same extent as in French. In 1756, Ware (London, folio) published what he called *A Complete Body of Architecture*. This, though in many respects an useful work, is far behind the wants of the present day. It is confined exclusively to Roman and Italian architecture; but it does not embrace the history even of these branches, nor does it contain a word on the sciences connected with construction. The details, therefore, not being sufficiently carried out, and many essential branches being entirely omitted, the work is not so generally useful as its name would imply. From these authorities, and many others, besides his own resources, the author of this encyclopædia has endeavoured to compress within the limits of one closely-printed volume all the elementary knowledge indispensable to the student and amateur; and he even ventures to indulge the belief that it will be found to contain information which the experienced professor may have overlooked.

Though, in form, the whole work pretends to originality, this pretension is not advanced for the whole of its substance. Not merely all that has long been known, but even the progressive discoveries and improvements of modern times, are usually founded on facts which themselves have little claims to novelty. As a fine architecture, though in its applications and changes inexhaustible, is in its first principles confined within certain limits; but the analysis of these principles and their relation to certain types have afforded some view of the subject which, it is believed, will be new even to those who have devoted their lives in the study of the art.

In those sciences on which the constructive power of the art is based, the author apprehended that he was entitled to more credit by the use of weightier authorities than his own. Accordingly, in the Second Book, he has adopted the algebra of Euler: and in other parts, the works of writers of established reputation. The use of Rossignol's geometry may indeed be disapproved by rigid mathematicians; but, considering the variety of attainments indispensable to the architectural student, the author was induced to shorten and smooth his path as much as possible, by refraining from burdening his memory with more mathematical knowledge than was absolutely requisite for his particular art. On this account, also, the instruction in algebra is not carried beyond the solution of cubic equations: up to that point it was necessary to prepare the learner for a due comprehension of the succeeding inquiries into the method of equilibrating arches and investigating the pressures of their different parts.

In all matters of importance, in which the works of previous writers have been used, the sources have been indicated, so that reference to the originals may be made. Upon the celebrated work of Rondelet above mentioned, on many learned articles in the *Encyclopédie Méthodique*, and on the works of Durand and other esteemed authors, large contributions have been levied; but these citations, it will be observed, appear for the first time in an English dress. In that part of the work which treats of the doctrine of arches, the chief materials, it will be seen, have been borrowed from Ron-

delet, whose views the author has adopted in preference to those he himself gave to the world many years ago, in a work which passed through several editions. Again, in the section on shadows, the author has not used his own treatise on Sciography. In the one case, he is not ashamed to confess his inferiority in so important a branch of the architect's studies; and in the other, he trusts that matured experience has enabled him to treat the subject in a form likely to be more extensively useful than that of treading in his former steps.

The sciences of which an architect should be cognisant are enumerated by Vitruvius at some length in the opening chapter of his first book. They are, perhaps, a little too much swelled, though the Roman in some measure qualifies the extent to which he would have them carried. "For," he observes, "in such a variety of matters" (the different arts and sciences) "it cannot be supposed that the same person can arrive at excellence in each." And again: "That architect is sufficiently educated whose general knowledge enables him to give his opinion on any branch when required to do so. Those unto whom nature hath been so bountiful that they are at once geometricians, astronomers, musicians, and skilled in many other arts, go beyond what is required by the architect, and may be properly called mathematicians in the extended sense of that word." Pythius, the architect of the temple of Minerva at Priene, differed, however, from the Augustan architect, inasmuch as he considered it absolutely requisite for an architect to have as accurate a knowledge of all the arts and sciences as is rarely acquired even by a professor devoted exclusively to one.

In a work whose object is to compress within a comparatively restricted space so vast a body of information as is implied in an account of what is known of historical, theoretical, and practical architecture, it is of the highest importance to preserve a distinct and precise arrangement of the subjects, so that they may be presented to the reader in consistent order and unity. Without order and method, indeed, the work, though filled with a large and valuable stock of information, would be but an useless mass of knowledge. In treating the subjects in detail, the alphabet has not been made to perform the function of an index, except in the glossary of the technical terms, which partly serves at the same time the purpose of a dictionary, and that of an index to the principal subjects noticed in the work. The following is a synoptical view of its contents, exhibiting its different parts, and the mode in which they arise from and are dependent on each other.

#### Book I. HISTORY OF ARCHITECTURE, considered in—

##### Chap. I. ORIGIN.

- |                         |  |
|-------------------------|--|
| 1. Wants of Man.        | 3. Different Sorts of Dwellings arising from different Occupations of Mankind. |
| 2. Origin and Progress. |  |

##### II. VARIOUS COUNTRIES.

- |                            |                              |
|----------------------------|------------------------------|
| 1. Druidical and Celtic.   | 8. Chinese.                  |
| 2. Pelasgic and Cyclopean. | 9. Mexican.                  |
| 3. Babylonian.             | 10. Arabian or Saracenic.    |
| 4. Persepolitan.           | 11. Grecian.                 |
| 5. Jewish.                 | 12. Etruscan.                |
| 6. Indian.                 | 13. Roman.                   |
| 7. Egyptian.               | 14. Byzantine and Romanesque |

- |              |                         |
|--------------|-------------------------|
| 15. Pointed. | 18. German.             |
| 16. Italian. | 19. Spain and Portugal. |
| 17. French.  | 20. Russia.             |

Chap. III. BRITISH ISLES.

- |   |                      |
|---|----------------------|
| 1. British Architecture from an early Period. | 6. Elizabethan.      |
| 2. Norman.                                    | 7. James I. to Anne. |
| 3. Early English.                             | 8. George I.         |
| 4. Ornamented English.                        | 9. George II.        |
| 5. Florid English or Tudor.                   | 10. George III.      |

Book II. THEORY OF ARCHITECTURE, founded on knowledge of—

Chap. I. CONSTRUCTION.

- |                            |                           |
|----------------------------|---------------------------|
| 1. Arithmetic and Algebra. | 7. Mensuration.           |
| 2. Geometry.               | 8. Mechanics and Statics. |
| 3. Practical Geometry.     | 9. Arches.                |
| 4. Plane Trigonometry.     | 10. Walls.                |
| 5. Conic Sections.         | 11. Mechanical Carpentry. |
| 6. Descriptive Geometry.   |                           |

✓ II. MATERIALS.

- |             |                                    |
|-------------|------------------------------------|
| 1. Stone.   | 8. Slates.                         |
| 2. Granite. | 9. Bricks and Tiles.               |
| 3. Marble.  | 10. Lime, Sand, Water, and Cement. |
| 4. Timber.  | 11. Glass.                         |
| 5. Iron.    | 12. Asphalte.                      |
| 6. Lead.    |                                    |
| 7. Zinc.    |                                    |

✓ III. USE OF MATERIALS IN —

- |                            |                               |
|----------------------------|-------------------------------|
| 1. Foundations and Drains. | 8. Glazing.                   |
| 2. Bricklaying and Tiling. | 9. Plastering.                |
| 3. Masonry.                | 10. Smithery and Ironmongery. |
| 4. Practical Carpentry.    | 11. Foundry.                  |
| 5. Joinery.                | 12. Painting and Gilding.     |
| 6. Slating.                | 13. Specifications.           |
| 7. Plumbery.               | 14. Measuring and estimating. |

IV. MEDIUM OF EXPRESSION BY—

- |                        |                      |
|------------------------|----------------------|
| 1. Drawing in general. | 3. Shadows.          |
| 2. Perspective.        | 4. Working Drawings. |

✓ III. PRACTICE OF ARCHITECTURE, as a Fine Art consists in —

Chap. I. KNOWLEDGE OF PRINCIPAL PARTS OF A BUILDING.—

- |                            |                                |
|----------------------------|--------------------------------|
| 1. Beauty in Architecture. | 14. Pilasters.                 |
| 2. The Orders.             | 15. Caryatides and Persians.   |
| 3. Tuscan Order.           | 16. Balustrades and Balusters. |
| 4. Doric Order.            | 17. Pediments.                 |
| 5. Ionic Order.            | 18. Cornices.                  |
| 6. Corinthian Order.       | 19. Profiles of Doors.         |
| 7. Composite Order.        | 20. Windows.                   |
| 8. Pedestals.              | 21. Niches and Statues.        |
| 9. Intercolumniations.     | 22. Chimney Pieces.            |
| 10. Arcades and Arches.    | 23. Staircases.                |
| 11. Orders above Orders    | 24. Ceilings.                  |
| 12. Arcades above Arcades. | 25. Proportions of Rooms.      |
| 13. Basements and Attics.  |                                |

II. COMBINATION OF PARTS BY—

- |  |  |
|--|--|
| 1. General Principles of composition.                  | 4. Horizontal and Vertical Combinations in Building. |
| 2. Drawings necessary in Composition.                  | 5. Subdivisions of Apartments and Points of Support. |
| 3. Caissons in Hemispherical and Cylindrical Vaulting. | 6. Combination of Parts in leading Forn.             |

## Chap. III. APPLICATION OF COMBINATION IN —

- |   |  |
|---|--|
| 1. General Observations,                      | 14. Exchanges.                           |
| 2. Bridges.                                   | 15. Custom Houses.                       |
| 3. Churches.                                  | 16. Theatres.                            |
| 4. Palaces.                                   | 17. Hospitals.                           |
| 5. Government Offices.                        | 18. Prisons.                             |

APPENDIX. — Laws relating to Building: Building Act — Chimney-Sweepers Act — Dilapidations — Compound Interest Tables and Valuation of Property.

GLOSSARY, containing also LIST OF PRINCIPAL ARCHITECTS and their Works, &c.

## INDEX.

Perfection is not attainable in human labour, and the errors and defects of this work will, doubtless, in due time be pointed out; but as the subject has occupied the author's mind during a considerable practice, he is inclined to think that these will not be very abundant. He can truly say that he has bestowed upon it all the care and energy in his power; and he alone is responsible for its errors or defects; — the only assistance he has to acknowledge being from his son, Mr. John Sebastian Gwilt, by whom the illustrative drawings were executed. No apology is offered for its appearance, inasmuch as the want of such a book has been felt by every architect at the beginning of his career. Not less is wanted a similar work on Civil Engineering, which the author has pleasure in stating is about to be shortly supplied by his friend, Mr. Edward Cresy.

Without deprecating the anger of the critic, or fearing what may be urged against his work, the author now leaves it to its fate. His attempt has been for the best, and he says with sincerity,

— “ Si quid novisti rectius istis  
Candidus imperti, si non his utere mecum.”

J. G.

*Abingdon Street, Westminster,  
30th September, 1842.*

P.S. — The author begs here to acknowledge the unremitting zeal of the printers of this work, and the obligations under which they have laid him by their care in its progress through the press. A few unavoidable errors have, however, occurred, notwithstanding every care; and the attention of the reader is requested to the “Errata” for their correction.

# CONTENTS.

## BOOK I.

### HISTORY OF ARCHITECTURE.

#### CHAP. I.

##### ORIGIN OF ARCHITECTURE.

	Page
SECT. 1. Wants of Man, and first Buildings - -	1
2. Origin and Progress of building - -	2
3. Different Sorts of Dwellings arising from different Occupations - -	3

### HISTORY OF ARCHITECTURE.

---

### CHAP. I.

#### ON THE ORIGIN OF ARCHITECTURE.

---

#### SECT. I.

##### WANTS OF MAN, AND FIRST BUILDINGS.

1. PROTECTION from the inclemency of the seasons was the mother of architecture. Of little account at its birth, it rose into light and life with the civilisation of mankind; and, proportionately as security, peace, and good order were established, it became, not less than its sisters, painting and sculpture, one method of transmitting to posterity the degree of importance to which a nation had attained, and the moral value of that nation amongst the kingdoms of the earth. If the art, however, be considered strictly in respect of its actual utility, its principles are restricted within very narrow limits; for the mere art, or rather science, of construction, has no title to a place among the fine arts. Such is in various degrees to be found among people of savage and uncivilised habits; and until it is brought into a system founded upon certain laws of proportion, and upon rules based on a refined analysis of what is suitable in the highest degree to the end proposed, it can pretend to no rank of a high class. It is only when a nation has arrived at a certain degree of opulence and luxury that architecture can be said to exist in it. Hence it is that architecture, in its origin, took the varied forms which have impressed it with such singular differences in different countries; differences which, though modified as each country advanced in civilisation, were, in each, so stamped, that the type was permanent, being refined only in a higher degree in their most important examples.

2. The ages that have elapsed, and the distance by which we are separated from the nations among whom the art was first practised, deprive us of the means of examining the shades of difference resulting from climate, productions of the soil, the precise spots upon which the earliest societies of man were fixed, with their origin, number, mode of life, and social institutions; all of which influenced them in the selection of one form in preference to another. We may, however, easily trace in the architecture of nations, the types of three distinct states of life, which are clearly discoverable at the present time; though in some cases the types may be thought doubtful.

## SECT. II.

## ORIGIN AND PROGRESS OF BUILDING.

3. The original classes into which mankind were divided were, we may safely assume, those of hunters, of shepherds, and of those occupied in agriculture; and the buildings for protection which each would require, must have been characterised by their several occupations. The hunter and fisher found all the accommodation they required in the clefts

FIG. 1. RUINS OF PETRA.

and caverns of rocks; and the indolence which those states of life induced, made them insensible or indifferent to greater comfort than such naturally-formed habitations afforded. We are certain that thus lived such tribes. Jeremiah (chap. xlix. 16.), speaking of the judgment upon Edom, says, "O thou that dwellest in the clefts of the rock, that holdest the height of the hill;" a text which of late has received ample illustration from travellers, and especially from the labours of Messrs. Leon de Laborde and Linant, in the splendid engravings of the ruins of Petra (fig. 1.). To the shepherd, the inhabitant of the plains wandering from one spot to another, as pasture became inadequate to the support of his flocks, another species of dwelling was more appropriate; one which he could remove with him in his wanderings: this was the tent, the type of the architecture of China, whose people were, like all the Tartar races, *nomades* or *scenites*, that is, shepherds or dwellers in tents. Where a portion of the race fixed its abode for the purposes of agriculture, a very different species of dwelling was necessary.

Solidity was required as well for the personal comfort of the husbandman as for preserving, from one season to another, the fruits of the earth, upon which he and his family were to exist. Hence, doubtless, the hut, which most authors have assumed to be the type of Grecian architecture.

4. Authors, says the writer in the *Encyc. Methodique*, in their search after the origin of architecture, have generally confined their views to a single type, without considering the modification which would be necessary for a mixture of two or more of the states of mankind; for it is evident that any two or three of them may co-exist, a point upon which more will be said in speaking of Egyptian architecture. Hence have arisen the most discordant and contradictory systems, formed without sufficient acquaintance with the customs of different people, their origin, and first state of existence.

5. The earliest habitations which were constructed after the dispersion of mankind from the plains of Sennaar (for there, certainly, as we shall hereafter see, even without the evidence of Scripture, was a great multitude gathered together), were, of course, proportioned to the means which the spot afforded, and to the nature of the climate to which they were to be adapted. Reeds, canes, the branches, bark, and leaves of trees, clay, and similar materials would be first used. The first houses of the Egyptians and of the people of Palestine were of reeds and canes interwoven. At the present day the same materials serve to form the houses of the Peruvians. According to Pliny (l. vii.), the first houses of the Greeks were only of clay; for it was a considerable time before that nation was acquainted with the process of hardening it into bricks. The Abyssinians still build with clay and reeds. Wood, however, offers such facilities of construction, that still, as of old, where it abounds, its adoption prevails. At first, the natural order seems to be that which Vitruvius describes in the first chapter of his second book. "The first attempt," says our author, "was the mere erection of a few spars, united together with twigs, and covered with mud. Others built their walls of dried lumps of turf, connected these walls together by means of timbers laid across horizontally, and covered the erections with reeds and boughs, for the purpose of sheltering themselves from the inclemency of the seasons. Finding, however, that flat coverings of this sort would not effectually shelter them in the winter season, they made their roofs of two inclined planes, meeting each other in a ridge at the summit, the whole of which they covered with clay, and thus carried off the rain." The same author

afterwards observes, "The woods about Pontus furnish such abundance of timber, that they build in the following manner. Two trees are laid level on the earth, right and left, at such distance from each other as will suit the length of the trees which are to cross and

FIG. 2.

EARLY TIMBER CONSTRUCTION.

connect them. On the extreme ends of these two trees are laid two other trees, transversely: the space which the house will enclose is thus marked out. The four sides being so set out, towers are raised, whose walls consist of trees laid horizontally, but kept perpendicularly over each other, the alternate layers yok- ing the angles.

The level inter-

stices, which the thickness of the trees alternately leave, is filled in with chips and mud. On a similar principle they form their roofs, except that gradually reducing the length of the trees which traverse from angle to angle, they assume a pyramidal form. They are covered with boughs, and thus, after a rude fashion of vaulting, their quadrilateral roofs are formed." The northern parts of Germany, Poland, and Russia still exhibit traces of this principle of building; and they are also found in Florida, Louisiana, and elsewhere, in various places. See *fig. 2*.

6. We shall not, in this place, pursue the discussion on the timber hut, which has certainly, with great appearance of probability, been so often said to contain within it the types of Grecian architecture, but shall, under that head, enlarge further on the subject.

### SECT. III.

#### DIFFERENT SORTS OF DWELLINGS ARISING FROM DIFFERENT OCCUPATIONS.

7. The construction of the early habitations of mankind required little skill and as little knowledge. A very restricted number of tools and machines was required. The method of felling timber, which uncivilised nations still use, namely, by fire, might have served all purposes at first. The next step would be the shaping of hard and infrangible stones into cutting tools, as is still the practice in some parts of the continent of America. These, as the metals became known, would be supplanted by tools formed of them. Among the Peruvians, at their invasion by the Spaniards, the only tools in use were the hatchet and the adze; and we may fairly assume that similar tools were the only ones known at a period of high antiquity. The saw, nails, the hammer, and other instruments of carpentry were unknown. The Greeks, who, as Jacob Bryant says, knew nothing of their own history, ascribe the invention of the instruments necessary for working materials to Dædalus; but only a few of these were known even in the time of Homer, who confines himself to the hatchet with two edges, the plane, the auger, and the rule. He particularises neither the square, compasses, nor saw. Neither the Greek word *πριων* (a saw), nor its equivalent, is to be found in his works. Dædalus is considered, however, by Goguet as a fabulous person altogether, the word meaning, according to him, nothing more than a skilful workman, a meaning which, he observes, did not escape the notice of Pausanias. The surmise is borne out by the non-mention of so celebrated a character, if he had ever existed, by Homer, and, afterwards, by Herodotus. The industry and perseverance of man, however, in the end, overcame the difficulties of construction. For wood, which was the earliest material, at length were substituted bricks, stone, marble, and the like; and edifices were reared of unparalleled magnificence and solidity. It seems likely, that bricks would have been in use for a considerable period before stone was employed in building. They were, probably, after moulding, merely subjected to the sun's rays to acquire hardness. These were the materials whereof the Tower of Babel was constructed. These also, at a very remote period, were used by the Egyptians. Tiles seem to have been of as high an antiquity as bricks, and to have been used, as in the present day, for covering roofs.

8. The period at which wrought stone was originally used for architectural purposes is

quite unknown, as is that in which cement of any kind was first employed as the medium of uniting masonry. They were both, doubtless, the invention of that race which we have mentioned as cultivators of land, to whom is due the introduction of architecture, properly so called. To them solid and durable edifices were necessary as soon as they had fixed upon a spot for the settlement of themselves and their families.

9. Chaldaea, Egypt, Phœnicia, and China are the first countries on record in which architecture, worthy the name, made its appearance. They had certainly attained considerable proficiency in the art at a very early period; though it is doubtful, as respects the three first, whether their reputation is not founded rather on the enormous masses of their works, than on beauty and sublimity of form. Strabo mentions many magnificent works which he attributes to Semiramis; and observes that, besides those in Babylonia, there were monuments of Babylonian industry throughout Asia. He mentions *λόφου* (high altars), and strong walls and battlements to various cities, as also subterranean passages of communication, aqueducts for the conveyance of water under ground, and passages of great length, upwards, by stairs. Bridges are also mentioned by him (lib. xvi.). Moses has preserved the names of three cities in Chaldaea which were founded by Nimrod (*Gen. x. 10.*). Ashur, we are told, built Nineveh; and (*Gen. xix. 4.*) as early as the age of Jacob and Abraham, towns had been established in Palestine. The Chinese attribute to Fohi the encircling of cities and towns with walls; and in respect of Egypt, there is no question that in Homer's time the celebrated city of Thebes had been long in existence. The works in India are of very early date; and we shall hereafter offer some remarks, when speaking of the extraordinary monument of Stonehenge, tending to prove, as Jacob Bryant supposes, that the earliest buildings of both nations, as well as those of Phœnicia and other countries, were erected by colonies of some great original nation. If the Peruvians and Mexicans, without the aid of carriages and horses, without scaffolding, cranes, and other machines used in building, without even the use of iron, were enabled to raise monuments which are still the wonder of travellers, it would seem that the mechanical arts were not indispensable to the progress of architecture; but it is much more likely that these were understood at an exceedingly remote period in Asia, and in so high a degree as to have lent their aid in the erection of some of the most stupendous works to which we have alluded.

10. The art of working stone, which lies the use of iron and a knowledge of the method of tempering it, was, I believe, the successor of Menes. It seems, however, possible that the ancient tools which were capable of acting upon stone, as well as the use of iron, may have been called upon earlier than the use of iron, as a material, for the climate does not favour the growth of timber; and granite were thus forced into use; and we know that, besides the facilities afforded by means of canals, as early as the time of Joseph waggons were in use. (*Gen. xlv. 1.*) We shall hereafter investigate the hypothesis of the architecture of Greece being founded on types of timber buildings, merely observing here, by the way, that many of the columns and entablatures of Egypt had existence long before the earliest temples of Greece; and therefore that, without recurrence to timber construction, prototypes for Grecian architecture are to be found in the venerable remains of Egypt, where it is quite certain wood was not generally employed as a material, and where the subterranean architecture of the country offers a much more probable origin of the style.

## CHAP. II.

### ARCHITECTURE OF VARIOUS COUNTRIES.

#### SECT. I.

##### DRUIDICAL AND CELTIC ARCHITECTURE.

11. If rudeness, want of finish, and the absence of all appearance of art, be criteria for judgment on the age of monuments of antiquity, the wonderful remains of Abury and Stonehenge must be considered the most ancient that have preserved their form so as to indicate the original plan on which they were constructed. The late Mr. Godfrey Higgins, a gentleman of the highest intellectual attainments, in his work on the Celtic Druids (published 1829), has shown, as we think satisfactorily, that the Druids of the British Isles were a colony of the first race of people, learned, enlightened, and descendants of the persons who escaped the deluge on the borders of the Caspian Sea; that they were the earliest occupiers of Greece, Italy, France, and Britain, and arrived in those places by a route nearly

along the forty-fifth parallel of north latitude; that, in a similar manner, colonies advanced from the same great nation by a southern line through Asia, peopling Syria and Africa, and arriving at last by sea through the Pillars of Hercules at Britain; that the languages of the western world were the same, and that one system of letters—viz. that of the Irish Druids—permeated the whole, was common to the British Isles and Gaul, to the inhabitants of Italy, Greece, Syria, Arabia, Persia, and Hindostan; and that one of the two alphabets (of the same system) in which the Irish MSS. are written—viz. the Beth-luis-nion—came by Gaul through Britain to Ireland; and that the other—the Bobeloth—came through the Straits of Gibraltar. Jacob Bryant thinks that the works called Cyclopean were executed at a remote age by colonies of some great original nation; the only difference between his opinion and that of Mr. Higgins being, that the latter calls them Druids, or Celts, from the time of the dispersion above alluded to.

12. The unhewn stones, whose antiquity and purport is the subject of this section, are found in Hindostan, where they are denominated "pandoo koolies," and are attributed to a fabulous being named Pandoo and his sons. With a similarity of character attesting their common origin, we find them in India, on the shores of the Levant and Mediterranean, in Belgium, Denmark, Sweden and Norway, in France, and on the shores of Britain from the Straits of Dover to the Land's End in Cornwall, as well as in many of the interior parts of the country. They are classed as follows:—1. The single stone, pillar, or obelisk. 2. Circles of stones of different number and arrangement. 3. Sacrificial stones. 4. Cromlechs and cairns. 5. Logan stones. 6. Tolmen or colossal stones.

13. (1.) *Single Stones.*—Passages abound in Scripture in which the practice of erecting single stones is recorded. The reader on this point may refer to *Gen. xxviii. 18. Judges, ix. 6., 1 Sam. vii. 12., 2 Sam. xx. 8., Joshua, xxiv. 27.* The single stone might be an emblem of the generative power of Nature, and thence an object of idolatry. That mentioned in the first scriptural reference, which Jacob set up in his journey to visit Laban his uncle, and which he had used for his pillow, seems, whether from the vision he had while sleeping upon it, or from some other cause, to have become to him an object of singular veneration; for he set it up, and poured oil upon it, and called it "Bethel" (the house of God). It is curious to observe that some pillars in Cornwall, assumed to have been erected by the Phœnicians, still retain the appellation. At first, these stones were of no larger dimension than a man could remove. The one just cited, and that of the Gûlgal of Joshua (*Josh. iv. 20.*); but that under an oak at Shechem was a great stone. And here we may notice a coincidence, that of the Bothel in Cornwall being set up in a place which, in its original purity to an oak which was near the spot, was called Bothel-ac; the last of the Scriptures that these single stones were erected, in the case of Jacob's Bethel, and in the case of the pillar at Shechem, to commemorate instances of divine interposition; sometimes, as in the case of Jacob and Laban (*Gen. xxxi. 48.*); sometimes, as in the case of Rachel's grave (*Gen. xxxvi. 20.*), according to the usual reckoning. They were occasionally, also, set up in honour of individuals, as in the instance of Absalom's pillar and others. The pillars of the patriarchs appear to have been erected in honour of the only true God, but wherever the Canaanites appeared, they seem to have been the objects of idolatrous worship, and to have been dedicated to Baal or the sun, or the other false deities, whose altars Moses ordered the Israelites to destroy. The similarity of pillars of single stones almost at the opposite sides of the earth, leaves no doubt in our mind of their being the work of a people of one common origin widely scattered; and the hypotheses of Bryant and Higgins sufficiently account for their appearance in places so remote from each other. In consequence, says the latter writer, of some cause, no matter what, the Hive, after the dispersion, casted and sent forth its swarms. One of the largest descended, according to Genesis (x. 2.), from Gomer, went north, and then west, pressed by succeeding swarms, till it arrived at the shores of the Atlantic Ocean, and ultimately colonised Britain. Another branch, observes the same author, proceeded through Sarmatia southward to the Euxine (Cimmerian Bosphorus); another to Italy, founding the states of the Umbrii and the Cimmerii, at Cuma, near Naples. Till the time of the Romans these different lines of march, like so many sheepwalks, were without any walled cities. Some of the original tribe found their way into Greece, and between the Carpathian mountains and the Alps into Gaul, scattering a few stragglers as they passed into the beautiful valleys of the latter, where traces of them in Druidical monuments and language are occasionally found. Wherever they settled, if the conjecture is correct, they employed themselves in recovering the lost arts of their ancestors.

14. To the Canaanites of Tyre and Sidon may be chiefly attributed the introduction of these primeval works into Britain. The Tyrians, inhabiting a small slip of barren land, were essentially and necessarily a commercial people, and became the most expert and adventurous sailors of antiquity. It has been supposed that the constancy of the needle to the pole—that path which no fowl knoweth, and which the vulture's eye hath not seen,"

was known to the Tyrians; and, indeed, it seems scarcely possible that, by the help of the stars alone, they should have been able to maintain a commerce for tin on the shores of Britain, whose western coast furnished that metal in abundance, and whose islands (the

3

FIG. 3. PILLAR OF RUDSTONE.

(*Archæologia*, vol. v. p. 95.), its depth underground equals its height above, as appeared from an experiment made by the late Sir William Strickland."

15. (2.) *Circles of Stone*.—The Israelites were in the habit of arranging stones to represent the twelve tribes of Israel (*Exod.* xxiv. 4.), and for another purpose. (*Deut.* xxvii. 2.) And in a circular form we find them set up by Joshua's order on the passage of the Israelites through Jordan to Gilgal (גלגל); a word in which the radical Gal or Gil (signifying a wheel) is doubled to denote the continued repetition of the action. In this last case, Joshua made the arrangement a type of the Lord ~~driving~~ driving away their reproach from them.

16. Though traces of this species of monument are found in various parts of the world, even in America, we shall confine our observations to those of Abury and Stonehenge, merely referring, by way of enumeration, to the places where they are to be found. Thus we mention Roilbrich in Oxfordshire, the Hurlers in Cornwall, Long Meg and her daughters in Cumberland, remains in Devonshire, Dorsetshire, at Stanton Drew in Somersetshire, and in Westmoreland. They are common in Wales, and are found in the Western Isles. There are examples in Iceland, Norway, Sweden, Denmark, and various parts of Germany. Clarke, in his description of the hill of Kushnulu Tepe in the Troad, observes, that all the way up, the traces of former works may be noticed, and that, on the summit, there is a small oblong area, six yards long and two broad, exhibiting vestiges of the highest antiquity; the stones forming the inclosure being as rude as those of Tiryns in Argolis, and encircled by a grove of oaks covering the ~~base~~ conical mountain. The entrance is from the south. Upon the east and west ~~sides~~ sides of the trees, are stones ranging like what we in England call Druidical circles. Three circles of stones are known in America, one of which stands upon a high rock on the banks of the river Winnipigon. The stupendous monument of Carnac in Brittany, of which we have above made mention, is not of a circular form; the stones there being arranged in eleven straight lines, from 30 to 33 ft. apart, some of which are of enormous size. They are said to have formerly extended three leagues along the coast. A description of this monument is given in vol. xxii. of the *Archæologia*.

17. Abury, or Avebury, in Wiltshire, of which we give a view in a restored state (*fig. 4.*), is a specimen of this species of building, in which the climax of magnificence was attained. Stukely, who examined the ruins when in much better preservation than at present, says, "that the whole figure represented a snake transmitted through a circle;" and that, "to make their representation more natural, they artfully carried it over a variety of elevations and depressions, which, with the curvature of the avenues, produces sufficiently the desired effect. To make it still more elegant and picture-like, the head of the snake is carried up the southern promontory of Hackpen Hill, towards the village of West Kennet; nay, the very name of the hill is derived from this circumstance;" for *acan*, he observes, signifies a serpent in the Chaldaic language. Dr. S. then goes on to state, "that the *dracontia* was a name, amongst the first-learned nations, for the very ancient sort of temples of which they could give no account, nor well explain their meaning upon it." The figure of the serpent extended two miles in length; and but a very faint idea can now be formed of what it was in its original state. Two double circles, one to the north and the other to the south of the centre, were placed within the large circle, which formed the principal body of the serpent, and from which branched out the head to Hackpen Hill, in the direction of

FIG. 4.

ABURY.

West Kennet, as one avenue; and the other, the tail, in the direction of Beckhampton. Dr. Stukely makes the number of stones, 652 in all, as under: —

Stones.		Stones.		Stones.	
The great circle	100	Central pillar and altar, south	2	Long stone.	2
Outer circle north of the centre	30	circle	2	A stone he calls the ring stone	1
Inner ditto	12	Kennet avenue	200	Closing stone of the tail	1
Outer circle, south	30	Beckhampton avenue	200		
Inner ditto	12	Outer circle of Hackpen	40	Total	652
Cove and altar stone, north circle	4	Inner ditto	18		

Of these, only seventy-six stones remained in the Kennet avenue in 1722. The large circle was enclosed by a trench or vallum upwards of 50 ft. in depth and between 60 and

70 ft. in width, leaving entrances open where the avenues intersected it. The colossal mound, called "Silbury hill," close to the Bath road, was probably connected in some way with the circle we have described, from the circumstance of the Roman road to Bath, made long afterwards, being diverted to avoid it. Dr. Owen thinks that the Abury circle was one of three primary circles in Great Britain, and that Silbury hill was the pile of Cyvrangon (heaping) characterised in the 14th Welsh triad; but the conjecture affords us no assistance in determining the people by whom the monument was raised. If it be in its arrangement intended to represent a serpent, it becomes immediately connected with ophiolatry, or serpent worship, a sin which beset the Israelites, and which would stamp it as proceeding from the central stamen of the hypothesis on which Mr. Higgins sets out. See Observations on Dracontia, by the Rev. John Bathurst Deane, *Archæol.* vol. xxv.

FIG. 5.

PLAN OF STONEHENGE.

ations on Dracontia, by the Rev. John Bathurst Deane, *Archæol.* vol. xxv.

"Æoliam Pitanen a læva parte relinquit,  
Factaque de saxo longi simulacra Draconis,"

which is a picturesque description of Abury.

18. Stonebenge, on Salisbury Plain, about seven miles from Salisbury and two miles

to the west of Ambresbury, is certainly more artificial in its structure than Abury, and its construction may therefore be safely referred to a later date. *Fig. 5.* is a restored plan of this wonder of the west, as it may well be called. The larger circle is 105 feet in diameter, and between it and the interior smaller circle is a space of about 9 feet. Within this smaller circle, which is half the height (8 feet) of the exterior one, was a portion of an ellipsis formed by 5 groups of stones, to which Dr. Stukely has given the name of trilithons, because formed by two vertical and one horizontal stone: the former are from 17 to 18½ feet high, the middle trilithon being the highest. Within this ellipsis is another of single stones, half the height of the trilithons. The outer circle was crowned with a course of stones similar to an architrave or epistylum, the stones whereof were let into or joggled with one another by means of egg-shaped tenons formed out of the vertical blocks. The ellipsis was connected in a similar manner. Within the inner elliptical enclosure was a block 16 ft. long, 4 ft. broad, and 20 in. thick. This has usually been called the altar stone. Round the larger circle, at the distance of 100 ft., a vallum was formed about 52 ft. in width, so that the external dimension of the work was a diameter of 420 ft. The vallum surrounding these sacred places seems to have been borrowed by the Canaanites in imitation of the enclosure with which Moses surrounded Mount Sinai, in order to prevent the multitude from approaching too near the sacred mysteries. The number of stones composing this monument is variously given. In the subjoined account we follow Dr. Stukely:—

	Stones.		Stones.
Great circle, vertical stones . . . . .	30	Stones within vallum . . . . .	2
Epistylia . . . . .	30	A large table stone . . . . .	1
Inner circle . . . . .	40	Distant pillar . . . . .	1
Vertical stones of outer ellipsis . . . . .	10	Another stone, supposed to have been opposite the entrance . . . . .	1
Epistylia to them . . . . .	5		
Inner ellipsis . . . . .	19		
Altar . . . . .	1	Total . . . . .	140

Northwards from Stonehenge, at the distance of a few hundred yards, is a large single stone, which, at the period of its being placed there, has been by some thought to have marked a meridian line from the centre of the circle.

19. *Fig. 6.* is a view of the present state of this interesting ruin from the west. Mr.

Fig. 6.

STONEHENGE.

Cunnington, in a letter to Mr. Higgins, gives the following account of the stones which remain of the monument:—"The stones on the outside of the work, those comprising the outward circle as well as the large (five) trilithons, are all of that species of stone called 'garsen' found in the neighbourhood; whereas the inner circle of small upright stones, and those of the interior oval, are composed of granite, hornstone, &c., most probably procured from some part of Devonshire or Cornwall, as I know not where such stones could be procured at a nearer distance."

20. Authors have in Stonehenge discovered an instrument of astronomy, and among them Maurice, whose view as to its founders coincides with those of the writers already cited, and with our own. We give no opinion on this point, but shall conclude the section by placing before the reader the substance of M. Bailly's notion thereon, recommending him to consult, in that respect, authorities better than we profess to be, and here expressing our own belief that the priests of ancient Britain were priests of Baal; and that the monuments, the subjects of this section, were in existence long before the Greeks, as a nation, were known, albeit they did derive the word Druid from *δρῦς* (an oak), and said that they themselves were *αὐτοχθόνες* (sprung from the earth).

21. M. Bailly says, on the origin of the sciences in Asia, that a nation possessed of profound wisdom, of elevated genius, and of an antiquity far superior to the Egyptians or Indians, immediately after the flood inhabited the country to the north of India, between the latitudes of 40° and 50°, or about 50° north. He contends that some of the most celebrated observatories and inventions relating to astronomy, from their peculiar character, could have taken place only in those latitudes, and that arts and improvements gradually

travelled thence to the equator. The people to whom his description is most applicable is the northern progeny of Brahmins, settled near the Imaus and in Northern Thibet. We add, that Mr. Hastings informed Maurice of an immemorial tradition that prevailed at Benares, which was itself, in modern times, the grand emporium of Indian learning, — that all that of India came from a country situate in  $40^{\circ}$  of N. latitude. On this Maurice says, "This is the latitude of Samarcand, the metropolis of Tartary; and, by this circumstance, the position of M. Bailly should seem to be confirmed. This is the country where, according to the testimony of Josephus and other historians cited by the learned Abbé Pezron, are to be found the first Celts, by whom all the temples and caves of India were made. Higgins observes on this, that the worship of the Mithraic bull existed in India, Persia, Greece, Italy, and Britain, and that the religion of the Druids, Magi, and Brahmins was the same.

22. (3.) *Sacrificial Stones*. — These have been confounded with the cromlech, but the difference between them is wide. They are simple stones, either encircled by a shallow trench (vallum) and bank (agger), or by a few stones. Upon these almost all authors concur in believing that human immolation was practised; indeed, the name blood, or blood-stones, which they bear in the north of Europe, seems to point to their infernal use. We do not think it necessary to pursue further inquiry into them, as they present no remarkable nor interesting features.

23. (4.) *Cromlechs and Cairns*. — The former of these seem to stand in the same relation to the large circles that the modern cell does to the conventual church of the Catholics. They consist of two or more sides, or vertical stones, and sometimes a back stone, the whole being covered with one not usually placed exactly horizontal, but rather in an inclining

position. We here (fig. 7.) give a representation of one, that has received the name of *Kil's Cotty House*, which lies on the road between Maidstone and Rochester, about a mile north-eastward from Aylesford church, and is thus described in the *Beauties of England and Wales*. It "is composed of four huge stones unwrought, three of them standing on end but inclined inwards, and supporting the fourth, which lies transversely over

Fig. 7. KIL'S COTTY HOUSE.

them, so as to leave an open recess beneath. The dimensions and computed weights of these stones are as follows: — height of that on the south side 8 ft., breadth  $7\frac{1}{2}$  ft., thickness 2 ft., weight 8 tons; height of that on the north side 7 ft., breadth  $7\frac{1}{2}$  ft., thickness 2 ft., weight  $8\frac{1}{2}$  tons. The middle stone is very irregular; its medium length as well as breadth may be about 5 ft., its thickness about 1 ft. 2 in., and its weight about 2 tons. The upper stone or impost is also extremely irregular; its greatest length is nearly 12 ft., and its breadth about  $9\frac{1}{2}$  ft.; its thickness is 2 ft., and its weight about  $10\frac{1}{2}$  tons: the width of the recess at bottom is 9 ft., and at top  $7\frac{1}{2}$  ft.; from the ground to the upper side of the covering stone is 9 ft. These stones are of the kind called Kentish rag. Many years ago there was a single stone of a similar kind and size to those forming the cromlech, about 70 yards to the north-west: this, which is thought to have once stood upright, like a pillar, has been broken into pieces and carried away." Another cromlech stood in the neighbourhood, which has been thrown down. The nonsense that has been gravely written upon this and similar monuments is scarcely worth mention. It will hardly be believed that there existed people who thought it was the sepulchral monument of king Catigern, from similarity of name, and others who consider it the grave of the Saxon chief, Horsa, from its proximity to Horsted. Cromlechs are found in situations remote indeed, a specimen being seated on the Malabar coast; and in the British isles they are so numerous, that we do not think it necessary to give a list of them.

24. The *cairn* or *carn* which we have in this section coupled with the cromlech, perhaps improperly, is a conical heap of loose stones. Whether its etymology be that of Rowland, from the words קרן קרני (kern-ned), a coped heap, we shall, from too little skill in Hebrew, not venture to decide; so we do not feel quite sure that, as has been asserted, they were raised over the bodies of deceased heroes and chieftains. Our notion rather inclines to their having been a species of altar, though the heap of stones to which Jacob gave the name of Galeed, if it were of this species, was rather a memorial of the agreement between him and Laban. It can scarcely be called an architectural work; but we should have considered our notice of the earlier monuments of antiquity incomplete without naming the cairn.

25. (5.) *Logan or Rocking Stones*. — These were large blocks poised so nicely on the points of rocks, that a small force applied to them produced oscillation. The weight of the celebrated one in Cornwall, which is granite, has been computed at upwards of 90 tons.

The use of these stones has been conjectured to be that of testing the innocence of persons accused of crime, the rocking of the stone being certain, unless wedged up by the judge of the tribunal, in cases where he knew the guilt of the criminal: but we think that such a purpose is highly improbable.

26. (6.) *Tolmen or Colossal Stones.* — The Tolmen, or hole of stone, is a stone of

FIG. 5. TOLMEN IN CORNWALL.

considerable magnitude, so disposed upon rocks as to leave an opening between them, through which an object could be passed. It is the general opinion in Cornwall that invalids were cured of their diseases by being passed through the opening above mentioned. "The most stupendous monument of this kind," (see fig. 8.) says Borlase, "is in the tenement of Mên, in the parish of Constantine, in Cornwall; it is one great oval pebble, placed on the points of two natural rocks, so that a man may creep under the great one, between the supporters, through a passage of about three feet wide, by as much high. The longest diameter of this stone is 33 ft., being in a direction due north and south. Its height, measured perpendicularly over the opening is, 14 ft. 6 in., and the breadth, in the widest part, 18 ft. 6 in., extending from east to west. I measured one half of the circumference, and found it, according to my computation,  $48\frac{1}{2}$  ft., so that this stone is 97 ft. in circumference, lengthwise, and about 60 ft. in girt, measured at the middle; and, by the best information, it contains about 750 tons." We close this section by the expression of our belief that the extraordinary monuments whereof we have been speaking are of an age as remote as, if not more so than, the pyramids of Egypt, and that they were the works of a colony of the great nation that was at the earliest period settled in central Asia, either through the swarm that passed north-west over Germany, or south-west through Phœnicia; for, on either route, but rather, perhaps, the latter, traces of gigantic works remain, to attest the wonderful powers of the people of whom they are the remains.

## SECT. II.

### PELASGIC OR CYCLOPEAN ARCHITECTURE.

27. Pelasgic or Cyclopean architecture, (for that as well as the architecture of Phœnicia, seems to have been the work of branches of an original similarly thinking nation) presents for the notice of the reader, little more than massive walls composed of huge pieces of rock, scarcely more than piled together without the connecting medium of cement of any species. The method of its construction, considered as masonry, to the eye of the architect is quite sufficient to connect it with what we have in the preceding section called Druidical or Celtic architecture. It is next to impossible to believe that all these species were not executed by the same people. The nature and principles of Egyptian art were the same, but the specimens of it which remain bear marks of being of later date, the pyramids only excepted. The Greek fables about the Cyclopeans have been sufficiently exposed by Jacob Bryant, who has shown that the Greeks knew nothing about their own early history. Herodotus (lib. v. cap. 6.) alludes to them under the name of Cadmians, saying they were particularly famous for their architecture, which he says they introduced into Greece; and wherever they came, erected noble structures remarkable for their height and beauty. These were dedicated to the Sun under the names of Elorus and Pelorus. Hence every thing great and stupendous was called Pelorian; and, transferring the ideas of the works to the founders, they made them a race of giants. Homer says of Polyphemus, —

Καὶ γὰρ Πωλύμ' ἐτίτυκτο πέλορον, οὐδὲ ἔκκει  
Ἄνδρες γὰρ σιτοφάγῳ, ἀλλὰ μὲν ὕληντι.

Virgil, too, describes him "*Ipse arduus, alta pulsat sidera.*" Famous as lighthouse builders, wherein a round casement in the upper story afforded light to the mariner, the Greeks turned this into a single eye in the forehead of the race, and thus made them a set of monsters. Of the race were Trophonius and his brother Agamedes, who, according to Pausanias (lib. ix.) contrived the temple at Delphi and the Treasury constructed to Ægeus. So great was the fame for building of the Cyclopeans that, when the Sybil in Virgil shows Æneas the place of torment in the shades below, the poet separates it from the regions of bliss by a Cyclopean wall: —

" — Cyclopum educta caminis  
Mœnia conspicio."

Æn. lib. vi. v. 630.

28. The walls of the city of Mycene are of the class denominated Cyclopean, thus denounced for ruin by Hercules in Seneca : —

“ ——— Quid moror ? majus mihi  
Bellum Mycenis restat, ut Cyclopea  
Eversa manibus mœnia nostris concidant.”

*Hercules Furens*, act. 4. v. 996.

29. The gate of the city and the chief tower were particularly ascribed to them (Pausanias, lib. ii.) Argos had also the reputation of being Cyclopean. But, to return to Mycene, Euripides, we should observe, speaks of its walls as being built after the Phœnician rule and method : —

——— Ως τα Κυκλωπων βαθα  
Φοινικι κανονι και τυκοις ηγλωσμενα.

*Hercules Furens*, v. 944.

30. *Fig. 9.* is a representation of a portion of the postern gate of the walls of Mycene, for the purpose of exhibiting to the reader the character of the masonry employed in it.

*Fig. 9.* PART OF THE WALLS OF MYCENE.

were built for Prætus, whom they made a king of that country.” The same author says that the Cyclopeans worshipped the sun under the symbol of a serpent ; thus again

connecting them with the builders of Abury noticed in page 6. *Fig. 10.* is a view of some portions of the walls of Tiryns, and for others we refer the reader to the *Travels in Albania*, by the Rev. Mr. Hughes.

*Fig. 10.* PART OF THE WALLS OF TIRYNS.

trium ; in the three last whereof the walls resemble those of Tiryns, Argos, and Mycene ; and at Fiesole, Arezzo, and other places.

33. We shall now return to some further particulars in relation to Tiryns and Mycene, from which a more distinct notion of these fortresses will be obtained ; but further investigation of those in Italy will hereafter be necessary, under the section on Etruscan architecture. The Acropolis of Tiryns, a little to the south-east of Argos, is on a mount rising about fifty

32. Mr. Hamilton (*Archæologia*) divides the specimens of Cyclopean buildings into four æras. In the first he includes Tiryns and Mycene, where the blocks composing the masonry are of various sizes, having or having had smaller stones in their interstices. Second, as at Julis and Delphi, masonry without courses, formed of irregular polygonal stones, whose sides fit to each other. Third, that in which the stones are laid in courses of the same height, but unequal in length of stones ; of this species are specimens in Bœotia, Argolis, and the Phœcian cities. Fourth and last, that in which the stones are of various heights, and always rectangular, whereof examples are found in Attica. It must here be observed that, in the Etrurian part of Italy, Cyclopean works exist, particularly of those which Mr. Hamilton places in the second æra ; as at Norba in Latium, Cora, Signia, and Ala-

feet above the level of the plain, the foundations of its inclosure being still perfect and traceable, as in the annexed figure (*fig. 11.*). The ancient city is thought to have sur-

Fig. 11.

PLAN OF THE ACROPOLIS OF TIRYNS.

rounded the fortress, and that formerly the city was nearer the sea than at present. Bryant, with his usual ingenuity, has found in its general form a type of the long ship of Danaus, which, we confess, our imagination is not lively enough to detect. On the east of the fortress are quarries, which furnish stone similar to that whereof it is built. It had entrances from the east and the west, and one at the south-eastern angle. That on the east, lettered A, is pretty fairly preserved, and is approached by an inclined access, B, 15 ft. wide, along the eastern and southern sides of the tower, C, which is 20 ft. square and 40 ft. high, passing, at the end of the last named side, under a gateway, composed of very large blocks of stone, that which forms the architrave being 10 ft. long, and over which, from the fragments lying on the spot, it is conjectured that a triangular stone was placed; but thereon is no appearance of sculpture. D is the present entrance. The general thickness of the walls is 25 ft., and they are formed by three parallel ranks of stones 5 ft. thick, thus leaving

FIG. 12. GALLERIES.

two ranges of galleries each 5 ft. wide and 12 ft. high. The sides of the galleries are formed by two courses of stone, and the roof by two other horizontal courses, sailing over so as to meet at their summit, and somewhat resembling a pointed arch. See *fig. 11.* That part of the gallery, *fig. 12.*, now uncovered, is about 90 ft. long, and has six openings or recesses towards the east, one whereof seems to have afforded a communication with some exterior building, of whose foundation traces are still in existence. The interval between these openings varies from 10 ft. 6 in. to 9 ft. 8 in.; the openings themselves being from 5 ft. 6 in. to 4 ft. 10 in. wide. It is probable that these galleries extended all round the citadel, though now only accessible where the walls are least perfect, at the southern part of the inclosure. There are no remains of the south-eastern portal. It appears to have been connected with the eastern gate by an avenue enclosed between the outer and inner curtain, of which avenue the use is not known. Similar avenues have been found at Argos and other ancient cities in Greece. The northern point of the hill is least elevated, and smaller stones have been employed in its wall. The exterior walls are built of rough stones, some of which are 9 ft. 4 in. in length and 4 ft. thick, their common size being somewhat less. When entire, the wall must have been 60 ft. high, and on the eastern side has been entirely destroyed. The whole length of the citadel is about 660 ft., and the breadth about 180 ft., the walls being straight without regard to inequality of level in the rock.

34. The Acropolis of Mycene was probably constructed in an age nearly the same as that of Tiryns. Pausanias mentions a gate on which two lions were sculptured, to which the name of the Gate of the Lions has been given (*fig. 13.*) These are still in their original position. It is situate at the end of a recess about 50 ft. long, commanded by projections of the walls, which are here formed of huge blocks of square stones, many placed on each other without breaking joint, which circumstance gives it a very inartificial appearance. The epistylum of the gate is a single stone 15 ft. long and 4 ft. 4 in. high. To the south of the gate above mentioned the wall is much ruined. In one part something like a tower is discernible, whose walls, being perpendicular while the curtain inclines a little inward from its base, a projection remained at the top by which an archer could defend the wall below. The blocks of the superstructure are of great size, those of the substructure much smaller. The gates excepted, the whole citadel is built of rough masses of rock, nicely adjusted and fitted to each other, though the smaller stones with which the

interstices were filled have mostly disappeared. The southern ramparts of the citadel and all the other walls follow the natural irregularity of the precipice on which they stand. At

Fig. 13. GATE OF THE LIONS.

its eastern point it is attached by a narrow isthmus to the mountain. It is a long irregular triangle, standing nearly east and west. The walls are mostly of well-jointed polygonal stones, although the rough construction occasionally appears. The general thickness of the walls is 21 ft., in some places 25; their present height, in the most perfect part, is 43 ft. There are, in some places, very slight projections from the walls, resembling towers, whereof the most perfect one is at the south-east angle, its breadth being 33 ft. and its height 43 ft. The size of the block whereon the lions are sculptured is 11 ft. broad at the base, 9 ft. high, and about 2 ft. thick, of a triangular form suited to the recess made for its reception. This block, in its appearance, resembles the green basalt of Egypt.

35. In this place we think it proper to notice a building at Mycene, which has been called by some the Treasury of Atreus, or the tomb of his son Agamemnon mentioned by Pausanias. This building at first misled some authors into a belief that the use of the arch was known in Greece at a very early period; but examination of it shows that it was formed by horizontal courses, projecting beyond each other as they rose, and not by radiating joints or beds, and that the surface was afterwards formed so as to give the whole the appearance of a pointed dome, by cutting away the lower angles (fig. 14.). It is probably the most ancient of buildings in

Fig. 14. TREASURY OF ATREUS.

Greece; and it is a curious circumstance that at New Grange, near Drogheda, in Ireland, there is a monument whose form, construction, and plan of access resemble it so strongly that it is impossible to consider their similarity the result of accident. A representation of this may be seen in the work by Mr. Higgins which we have so often quoted, and will, we think, satisfy the reader of the great probability of the hypothesis hereinbefore assumed having all the appearance of truth. By the subjoined plan (fig. 15.) it will be seen that a space 20 ft. wide, between the two walls, conducts us to the entrance, which is 9 ft. 6 in. at the base, 7 ft. 10 in. at the top, and about 19 ft. high. The entrance passage is 18 ft. long and leads to the main chamber, which, in its general form, has some resemblance to a bee-hive, whose diameter is about 48 ft. and height about 49. (fig. 16 ) The blocks are placed in courses as above shown, 34 courses being at present visible. They are laid with the greatest precision, without cement, and are unequal in size. Their average height may be taken at 2 ft., though to a spectator

Fig. 15. PLAN OF TREASURY OF ATREUS.

on the floor, from the effect of the perspective, they appear to diminish very much towards the vertex. This monument has a second chamber, to which you enter on the right from the larger one just described. This is about 27 ft. by 20, and 19 ft. high; but its walls, from the obstruction of the earth, are not visible. The doorway to it is 9½ ft. high, 4 ft. 7 in. wide at the base, and 4 ft. 3 in. at the top. Similar to the larger or principal doorway, it has a triangular opening over its lintel. The stones which fitted into these triangular openings were of enormous dimensions, for the height of that over the principal entrance is 12 ft., and its breadth 7 ft. 8 in. The vault has been either lined with metal or ornamented with some sort of decorations, inasmuch as a number of bronze nails are found fixed in the stones up to the summit. The lintel of the door consists of two pieces of stone, the largest whereof is 27 ft. long, 17 ft. wide, and 3 ft. 9 in. thick, calculated, therefore, at 133 tons weight; a mass which can be compared with none ever used in building, except those at Balbec and in Egypt. The other lintel is of the same height, and probably (its ends are hidden) of

the same length as the first. Its breadth, however, is only one foot Its exterior has two parallel mouldings, which are continued down the jambs of the doorway.

Fig. 16.

CHAM.

36. The stone employed is of the hardest rocks, and the contiguous Mount Eubora

Fig. 17. A black and white photograph showing the exterior of a building with a triangular pediment and a doorway. The text 'at a trian' and 'OF ATRUC' is visible above the doorway.

present en  
parallel

ful breccia, of which the neighbouring It is the hardest and compactest breccia which Greece produces, resembling the antique marble called Breccia Tracagnina antica, sometimes found among the ruins of Rome. Near the gate lie some masses of rosso antico decorated with guilloche-like and zigzag ornaments, and a columnar base of a Persian character. Some have supposed that these belonged to the decorations of the doorway; but we are of a different opinion, inasmuch as they destroy its grand character. We think if this were the tomb of Agamemnon, they were much more likely to have been a part of the shrine in which the body or ashes were deposited.

37. It is conjectured that the treasury of Minyas king of Orchomenus, whereof Pausanias speaks, bore a resemblance to the building we have just described; and it is very probable that all the subterranean chambers of Greece, Italy, and Sicily were very similarly constructed. Fig. 17. represents the entrance to the building from the outside. As the architecture of the early races whereof we have been speaking will be further discussed in investigating other monuments, we do not

Fig. 17.

TREASURY OF MINYAS.

think it necessary to enlarge further in this place on what we have termed Pelasgic or Cyclopean architecture.

### SECT. III.

## BABYLONIAN ARCHITECTURE.

38. The name prefixed to this section must not induce the reader to suppose we shall be able to afford him much instruction on this interesting subject. The materials are scanty; the monuments, though once stupendous, still more so. "If ever," says Keith, in his *Evidence of the Truth of the Christian Religion*, "there was a city that seemed to bid defiance to any predictions of its fall, that city was Babylon. It was for a long time the most famous city in the Old World. Its walls, which were reckoned among the wonders of the world, appeared rather like the bulwarks of nature than the workmanship of man." The city of Babylon is thus described by ancient writers. It was situated in a plain of vast extent, and divided into two parts by the river Euphrates, which was of considerable width at the spot. The two divisions of the city were connected by a massive bridge of masonry strongly connected with iron and lead; and the embankments to prevent inroads of the river were formed of the same durable materials as the walls of the city. Herodotus says that the city itself was a perfect square enclosed by a wall 480 furlongs in circumference, which would make it eight times the size of London. It is said to have had numbers of houses three or four stories in height, and to have been regularly divided into streets running parallel with each other, and cross ones opening to the river. It was surrounded by a wide and deep trench, from the earth whereof, when excavated, square bricks were formed and baked in a furnace. With these, cemented together through the medium of heated bitumen intermixed with reeds to bind together the viscid mass, the sides of the vast walls above mentioned were constructed. At certain intervals watch-towers were placed, and the city was entered by principal divisions of the city a stupendous public monument was erected. Rennel thinks that on the eastern side stood the temple of Belus; in the other three strongly fortified enclosure, the royal palace. The former was a square being two furlongs in extent. The tower erected on its centre was a square and the same in height, thus making it higher than the largest of the pyramids. The furlong to contain only 500 feet. On this tower as a base were raised, in addition, seven other lofty towers, and the whole statue of the god Belus 40 feet high.

Fig. 18. TEMPLE OF HELUS.

18., in which the dotted lines show the remains, according to Sir R. K. Porter's account of his Travels. The palace, serving also as a temple, stood on an area  $1\frac{1}{2}$  mile square, and was surrounded by circular walls, which, according to Diodorus, were decorated with sculptured animals resembling life, painted in their natural colours, on the bricks of which they were depicted, and *afterwards burnt in*. Such was the city of Babylon in its meridian splendour, that city whose founder (if it were not Nimrod, sometimes called Belus,) is unknown. Great as

it was, it was enlarged by Semiramis, and still further enlarged and fortified by Nebuchadnezzar. We shall now present, from the account of Mr. Rich, a gentleman who visited the spot near thirty years ago, a sketch of what the city now is. The first grand mass of ruins marked A (*fig. 19.*), which the above gentleman describes, he says extends 1100 yards in length and 800 in its greatest breadth, in figure nearly resembling a quadrant; its height is irregular, but the most elevated part may be about 50 or 60 ft. above the level of the plain, and it has been dug into for the purpose of procuring bricks. This mound Mr. R. distinguishes by the name of Amran. On the north is a valley 550 yards long, and then the second grand heap of ruins, whose shape is nearly a square of 700 yards long and broad; its south-west angle being connected with the north-west angle of the mounds of Amran by a high ridge nearly 100 yards in breadth. This is the place where Beauchamp made his observations, and is highly interesting from every vestige of it being composed of buildings far superior to those whereof there are traces in the eastern quarter. The bricks are of the finest description, and, notwithstanding this spot being the principal magazine of them and constantly used for a supply, are still in abundance. The operation of extracting the bricks has caused much confusion, and increased the difficulty of deciphering the use of this mound. In some places the solid mass has been bored into, and the superincumbent strata falling in, frequently bury workmen in the rubbish. In all these excavations walls of burnt brick laid in lime mortar of a good quality are to be seen; and among the ruins are to be found fragments of alabaster vessels, fine earthenware, marble, and great quantities of varnished tiles, whose glazing and colouring are surprisingly fresh. "In a

hollow," observes Mr. Rich, "near the southern part, I found a sepulchral urn of earthen-

Fig. 19. PLAN OF BABYLON.

ware, which had been broken in digging, and near it lay some human bones, which pulverised with the touch." Not more than 200 yards from the northern extremity of this mound, is a ravine near 100 yards long, hollowed out by those who dig for bricks, on one of whose sides a few yards of wall remain, the face whereof is clear and perfect, and appears to have been the front of some building. The opposite side is so confused a mass of rubbish, that it looks as if the ravine had been worked through a solid building. Under the foundations at the southern end was discovered a subterranean passage floored and walled with large bricks in bitumen, and covered over with pieces of sandstone a yard thick and several yards long, on which the pressure is so great as to have pushed out the side walls. What was seen was near seven feet in height, its course being to the south. The upper part of the passage is cemented with bitumen, other parts of the ravine with mortar, and the bricks have all writing on them. At the northern end of the ravine an excavation was made, and a statue of a lion of colossal dimensions, standing on a pedestal of coarse granite and rude workmanship, was discovered. This was about the spot marked E on the plan. A little to the west of the ravine at B is a remarkable ruin called the Kasr or Palace, which, being uncovered, and partly detached from the rubbish, is visible from a considerable distance. It is "so surprisingly fresh," says the author, "that it was only after a minute inspection I was satisfied of its being in reality a Babylonian remain." It consists of several walls and piers, in some places ornamented with niches, and in others strengthened by pilasters of burnt brick in lime cement of great tenacity. The tops of the walls have been broken down, and they may have been much higher. Contiguous to this ruin is a heap of rubbish, whose sides are curiously streaked by the alternation of its materials, probably unburnt bricks, of which a small quantity were found in the neighbourhood, without however any reeds in their interstices. A little to the N. N. E. of it is the famous tree which the natives call Athell. They say it existed in ancient Babylon, and was preserved by God that it might afford a convenient place to Ali for tying up his horse after the battle Hellah! "It is an evergreen," says Mr. R., "something resembling the *lignum vitæ*, and of a kind, I believe, not common in this part of the country, though I am told there is a tree of the description at Bassora." The valley which separates the mounds just described from the river is white with nitre, and does not now appear to have had any buildings upon it except a small circular heap at D. The whole embankment is abrupt, and shivered by the action of the water. At the narrowest part E, cemented into the burnt brick wall, there were a number of urns filled with human bones which had not undergone the action of fire. From a considerable quantity of burnt bricks and other fragments of building in the water the river appears to have encroached here.

39. A mile to the north of the Kasr, and 950 yards from the bank of the river, is the last ruin of this series, which Pietro della Valle, in 1616, described as the tower of Belus, in which he is followed by Rennell. The natives call it, according to the vulgar Arab pronunciation of those parts, Mujelibè, which means overturned. They sometimes also apply the same term to the mounds of the Kasr. This is marked F on the plan. "It is of an oblong shape, irregular in its height and the measurement of its sides, which face the cardinal points, the northern side being 200 yards in length, the southern 219, the eastern 182, and the western 136. The elevation of the south-east or highest angle, 141 feet. The western face, which is the least elevated, is the most interesting on account of the appearance of building it presents. Near the summit of it appears a low wall, with interruptions, built of unburnt bricks mixed up with chopped straw or reeds and cemented with clay mortar of great thickness." The south-west angle seems to have had a turret, the others are less perfect. The ruin is much worn into furrows from the action of the weather, penetrating considerably into the mound in some places. The summit is covered with heaps of rubbish, among which fragments of burnt brick are found, and here and there

whole bricks with inscriptions on them. Interspersed are innumerable fragments of pottery, brick, bitumen, pebbles, vitrified brick or scoria, and even shells, bits of glass, and mother of pearl.

Fig. 20.

NORTHERN FACE OF THE MUEJILIBE.

The northern face of the Muejilibe (*fig. 20.*) contains a niche of the height of a man, at the back whereof a low aperture leads to a small cavity, whence a passage branches off to the right till it is lost in the rubbish. It is called by the natives the serdaub or cellar, and Mr. Rich was informed that four years previous to his survey, a quantity of marble was taken out from it, and a coffin of mulberry wood, in which was contained a human body enclosed in a tight wrapper, and apparently partially covered with bitumen, which crumbled into dust on exposure to the air. About this spot Mr. R. also excavated and found a coffin containing a skeleton in high preservation, whose antiquity was placed beyond dispute by the attachment of a brass bird to the outside of the coffin, and inside an ornament of the same material, which had seemingly been suspended to some part of the skeleton. On the western side of the river there is not the slightest vestige of ruins excepting opposite the mass of Amran, where there are two small mounds of earth in existence.

40. The most stupendous and surprising mass of the ruins of ancient Babylon is situate in the desert, about six miles to the south-west of Hellah. It is too distant to be shown on the block plan above given. By the Arabs it is called Birs Nemroud; by the Jews,

Nebuchadnezzar's Prison. Mr. Rich was the first traveller who gave any account of this ruin, of which *fig. 21.* is a representation; and the description following we shall present in Mr. Rich's own words. "The Birs Nemroud is a mound of an oblong figure, the total circumference of which is 762 yards. At the eastern side it is cloven by a deep furrow, and is not more than fifty or sixty feet high; but at the western it rises in a conical figure to the elevation of 198 ft., and on its summit is a solid pile of brick 37 ft. high by 28 in breadth, diminishing in thickness to the top, which is broken and irregular, and rent by a large fissure extending through a third of its height. It is perforated by small square holes disposed in rhomboids. The fine burnt bricks of which it is built have inscriptions on them; and so admirable is the cement, which appears to be lime mortar,

Fig. 21.

BIRS NEMROUD.

that, though the layers are so close together that it is difficult to discern what substance is between them, it is nearly impossible to extract one of the bricks whole. The other parts of the summit of the hill are occupied by immense fragments of brickwork, of no determinate figure, tumbled together and converted into solid vitrified masses, as if they had undergone the action of the fiercest fire or been blown up with gunpowder, the layers of the bricks being perfectly discernible,—a curious fact, and one for which I am utterly incapable of accounting. These, incredible as it may seem, are actually the ruins spoken of by Pêre Emanuel (See *D'Anville, sur l'Euphrate et le Tigre*), who takes no sort of notice of the prodigious mound on which they are elevated." The mound is a majestic ruin, and of a people whose powers were not lost, if the hypothesis brought before the reader in the previous section on Celtic and Druidical architecture be founded on the basis of truth, but shown afterwards, on their separation from the parent stock, in Abury, Stonehenge, Carnac, and many other places. Ruins to a considerable extent exist round the Birs Nemroud; but for our purpose it is not necessary to particularise them. The chance (for more the happiest conjecture would not warrant) of conclusively enabling the reader to come to a certain and definite notion of the venerable city, whereof it is our object to give him a faint idea, is far too indefinite to detain him and exhaust his patience. One circumstance, however, we must not omit; and again we shall use the words of the traveller to whom we are under so many obligations. They are,—"To these ruins I must add one, which, though not in the same direction, bears such strong characteristics of a Babylonian origin, that it would be

improper to omit a description of it in this place. I mean Akerkouf, or, as it is more generally called, Nimrod's Tower; for the inhabitants of these parts are as fond of attributing every vestige of antiquity to Nimrod as those of Egypt are to Pharaoh. It is situate ten miles to the north-west of Bagdad, and is a thick mass of unburnt brickwork, of an irregular shape, rising out of a base of rubbish; there is a layer of reeds between every fifth or sixth (for the number is not regulated) layer of bricks. It is perforated with small square holes, as the brickwork at the Birs Nemroud; and about half way up on the east side is an aperture like a window; the layers of cement are very thin, which, considering it is mere mud, is an extraordinary circumstance. The height of the whole is 126 ft.; diameter of the largest part, 100 ft.; circumference of the foot of the brickwork above the rubbish, 300 ft.; the remains of the tower contain 100,000 cubic feet. (*Vide Ives's Travels*, p. 298.) To the east of it is a dependent mound, resembling those at the Birs and Al Hheimar."

41. The inquiry (following Mr. Rich) now to be pursued is that of identifying some of the remains which have been described with the description which has been left of them. And, first, of the circuit of the city. The greatest circumference of the city, according to the authors of antiquity, was 480 stadia (supposed about 500 ft. each), the least 360. Strabo, who was on the spot when the walls were sufficiently perfect to judge of their extent, states their circuit at 385 stadia. It seems probable that within the walls there was a quantity of arable and pasture ground, to enable the population to resist a siege; and that, unlike modern cities, the buildings were distributed in groups over the area inclosed; for Xenophon reports that when Cyrus took Babylon (which event happened at night) the inhabitants of the opposite quarter of the town were not aware of it till the third part of the day; that is, three hours after sunrise. The accounts of the height of the walls all agree in the dimension of 50 cubits, which was their reduced height from 350 ft. by Darius Hystaspes, in order to render the town less defensible. The embankment of the river with walls, according to Diodorus 100 stadia in length, indicates very a valuable engineering skill; but the most wonderful structure of the city was the tower, pyramid or pulchre of Belus, whose base, according to Strabo, was a stadium on each side. It was an enclosure of two miles and a half, and contained the temple in which divine Belus were paid to the tutelary deity of Babylon. The main interest attached to the tower of Belus arises from a belief of its identity with the tower which we learn from Scripture (*Gen. xi.*) the descendants of Noah, with Belus at their head, constructed in the plains of Shinar. The two masses of ruins in which this tower must be sought, seem to be the Birs Nemroud, whose four sides are 2286 English feet in length; and the Mujelibé, whose circumference is 2111 ft. Now, taking the stadium at 500 ft., the tower of Belus, according to the accounts, would be 2000 ft. in circumference; so that both the ruins agree, as nearly as possible, in the requisite dimensions, considering our uncertainty respecting the exact length of the stadium. Mr. Rich evidently inclines to the opinion that the Birs Nemroud is the ruin of this celebrated temple, though he allows "a very strong objection may be brought against the Birs Nemroud in the distance of its position from the extensive remains on the eastern bank of the Euphrates, which for its accommodation would oblige us to extend the measurement of each side of the square to nine miles, or adopt a plan which would totally exclude the Mujelibé, all the ruins above it, and most of those below: even in the former case, the Mujelibé and the Birs would be at opposite extremities of the town close to the walls, while we have every reason to believe that the tower of Belus occupied a central situation."

42. The citadel or palace was surrounded by a wall whose total length was 60 stadia, within which was another of 40 stadia, whose inner face was ornamented with painting,—a practice (says Mr. Rich) among the Persians to this day. Within the last-named wall was a third, on which hunting subjects were painted. The old palace was on the opposite side of the river, the outer wall whereof was no larger than the inner wall of the new one. Above the palace or citadel were, according to Strabo, the hanging gardens, for which, in some respects, a site near the Mujelibé would sufficiently answer, were it not that the skeletons found there "embarrass almost any theory that may be formed on this extraordinary pile."

43. As yet, no traces have been found of the tunnel under the Euphrates, nor of the obelisk which Diodorus says was erected by Semiramis; it is not, however, impossible that the diligence and perseverance of future travellers may bring them to light. Rich believes that the number of buildings within the city bore no proportion to the extent of the walls,—a circumstance which has already been passingly noticed. He moreover thinks that the houses were, in general, small; and further, that the assertion of Herodotus, that it abounded in houses of two or three stories, argues that the majority consisted of only one. He well observes, "The peculiar climate of this district must have caused a similarity of habits and accommodation in all ages; and if, upon this principle, we take the present fashion of building as some example of the mode heretofore practised in Babylon, the houses that had more than one story must have consisted of the ground floor, or *basse-cour*, occupied by stables, magazines, and serdaubs or cellars, sunk a little below the ground, for

the comfort of the inhabitants during the heat; above this a gallery with the lodging rooms opening into it; and over all the flat terrace for the people to sleep on during the summer." In these observations we fully concur with the author, believing that climate and habits influence the arts of all nations.

44. Vastness of dimension, rather than refined art, may be reasonably inferred of the Babylonian architecture; the sculptures which have been seen are those of a people not so advanced in art as the Egyptians. From the similarity of the arrow-headed characters on the bricks found about the ruins of Babylon to those which appear on the ruins of Persepolis, we may fairly conjecture a similarity of habits and taste between the people of the two cities; of the latter we have more perfect remains than of the former, of which we shall furnish our readers with some examples in the next section. In Asia, about the provinces of which we have spoken, must be sought the first notions of the art. There its wonders first appeared; there it first developed its power. Greater almost at its birth than ever afterwards, it seems all at once to have risen, as respects absolute grandeur, to the highest state of which it was there susceptible; and, degenerating successively under the hands of other people, we may reckon by the periods of its decay the epochs of its duration.

45. No trace of the arch has been found in the ruins either at the Kasr or in the passages at the Mujelibé. Massy piers, buttresses, and pilasters supplied the place of the column. The timber they used was that of the date tree, posts of which were used in their domestic architecture, round which, says Strabo, they twist reeds and apply a coat of paint to them. Thickness of wall was obtained by casing rubble work with fine brick, of which two sorts were made. The one was merely dried in the sun, the other burned in a kiln. The latter was 13 in. square and 3 in. thick, with varieties for different situations in the walls. They are of various colours. The sun-dried is considerably larger than the kiln-dried. There is reason for believing that lime cement was ~~never~~ generally used than bitumen or clay; indeed, Niebuhr says that the bricks laid ~~in~~ were easily separated, but that where mortar had been employed no force could ~~separate~~ them from each other without breaking them in pieces.

## Sec. IV.

### PERSEPOLITAN AND PERSIAN ARCHITECTURE.

46. Persepolis, the ancient capital of Persia, whereof the few ruins now remaining we are about to describe, was seated (lat.  $30^{\circ} 40'$  N., long.  $84^{\circ}$  E.) in the great plain of Merdasht or Istakhr, one of the most fertile in the world, being watered in all directions by rivulets and artificial drains, which ultimately unite in the Bundemir, the ancient Araxes. The site of this city, destroyed two thousand years since, would, like Memphis, have scarcely left a vestige by which it could have been identified, but for the celebrated ruins of Chel-Minar (*fig* 22.), which are believed to be the remains of that

Fig. 22.

RUINS OF PERSEPOLIS.

ancient palace of the masters of Asia to which Alexander set fire in a moment of madness and debauch. The information we are about to give on this subject is obtained from De Bruyn, who examined the ruins with great attention in 1704, with some reference also to Niebuhr and Sir R. K. Porter, the latest traveller who has published any account of them.

47. The ruins are situated at the foot and to the west of the mountain Kulirag-met. On three sides the walls are remaining, the mountain to the east forming the other side

From north to south the extent is 600 paces (1425 ft.), and 390 (802 ft.) from west to east to the mountain on the south side, having no stairs on that side; average height about 18 ft. 7 in. On the north side it is 410 paces (926 ft.) from east to west, and the wall is 21 ft. high in some places. At the north-west corner of the wall, about 80 paces in extent westward, are some rocks before the principal staircase. On mounting the steps there is found a large platform 400 paces in extent towards the mountain. Along the wall on three

FIG. 23.

PLAN OF PERSEPOLIS.

51 ft. 4 in. wide. The upper flights are separated from the lower by a wall which runs through at the upper landing. The upper flights are in forty-eight steps, and are cut out of single blocks of the rock. The upper landing is seventy-five feet between the flights.

48. Forty-two feet from the landing, at B, are two large portals and two columns (originally four). The bottom of the first is covered with two blocks of stone, which fill two thirds of the space; the other third having been destroyed by time. The second portal is more covered by the earth than the first, by five feet. They are 22 ft. 4 in. deep, and 13 ft. 4 in. wide. On the interior side-faces of their piers, and nearly the whole length of them, are large figures of bulls, cut in bas-relief. The heads of these animals are entirely destroyed; and their breasts and fore feet project from the piers: the two of the first portal face to the staircase, and those of the other face towards the mountain. On the upper part of the piers there are some arrow-headed characters, too small to be made out

FIG. 24. FIGURE ON A PORTAL AT PERSEPOLIS.

from below. The remains of the first portal are 39 ft. high, and of the second 28 ft. The base of the piers is 5 ft. 2 in. high, and projects inwards; and the bases upon which the figures stand are 1 ft. 2 in. high. We may here observe that the figures on the further portal have the body and legs of a bull, an enormous pair of wings (*fig. 24.*) projecting from the shoulders, and the heads looking to the east show the faces of men. On the head is a cylindrical diadem, on both sides of which horns are clearly represented winding from the brows upwards to the front of the crown; the whole being surmounted with a sort of coronet, formed of a range of leaves like the lotus, and bound with a fillet carved like roses. The two columns (at Sir R. K. Porter's visit only one remained) are the most perfect among the ruins, and are 54 ft. high. At the distance of fifty-two feet south-eastward from the second portico is a water-trough cut out of a single stone 20 ft. long and 17 ft. 5 in. broad, and standing 3 ft. high from the ground. From hence to the northern wall of the platform is covered with fragments; and the remains of one column not channelled as the others are; this is 12 ft. 4 in. high

49. At one hundred and seventy-two feet from the portals, southward, is another staircase of two flights (lettered C), one west and the other east. On the top of the ramp of the steps are some foliages, and a lion tearing to pieces a bull, in bas-relief, and larger than nature. This staircase is half buried. The western flight has twenty-eight steps, and the other, where the ground is higher, has only eighteen. These steps are 17 ft. long, 3 in. high, and 14½ in. wide. The wall of the landing is sculptured with three rows of figures, one above the other, and extending ninety-eight feet. The faces of these inner terrace walls

Fig 25. BAS-RELIEF AT PERSEPOLIS.

are all decorated with bas-reliefs, of which *fig. 25.* is a specimen. On arriving at the top of this staircase, was found another large platform, paved with large blocks of stone; and at the distance of twenty-two feet two inches from the parapet of the landing, are the most northern columns (lettered D), originally twelve in number, whereof in Sir R. K. Porter's time only one remained. At seventy-one feet southward from these stood thirty-six columns more, at intervals of twenty-two feet two inches from each other, whereof only five now remain; the bases, however, of all the others are in their places, though most of them are much damaged. This group of columns is lettered E. To the east and west of the last-named group are two other groups of twelve each marked F and G, whereof five still remain in the eastern one, and four in the western one. The columns of the central group are fifty-five feet high; and those of the other three groups are sixty feet in height. To the south of the three groups of columns is situate the most raised building on these ruins. On the east, towards the mountain, a large mass of ruins is visible (lettered H), consisting of portals, passages, windows, &c. The first are decorated with figures on the interior; and the whole plot on which they stand is 95 paces from east to west, and about 125 paces from north to south. The centre part of the plot is covered with fragments of columns and other stones; and in the interior part there seems to have been a group of seventy-six columns, whereof none are represented by Sir R. K. Porter, nor are they shown in either of Le Bruyn's views. The highest building as to level, marked I, is 118 ft. distant from the columns lettered G. Some foundations are visible in front of this building, to which there is not the slightest trace of a staircase. At fifty-three feet from the façade of it to the right is a staircase of double flight, marked K, where again bassi relievi are to be found, near which are the remains of some portals which Le Bruyn thinks were destroyed by an earthquake. The next ruin (L) is 54½ ft. in extent, and has portals similar to those in other parts of the place. To its north, M exhibits uniform features, with windows, and what travellers have agreed to call niches, which are nothing more than square-headed recesses. Sculpture here again abounds, whereof we do not think a description necessary, as in *fig. 25.* a specimen of it has been given, sufficient to indicate its character. Behind this edifice is another, in some respects similar, except that it is thirty-eight feet longer. It is marked N on the plan. One hundred feet to the south of this last set of ruins (lettered O), Sir R. K. Porter seems to have found traces of columns, which, if we read Le Bruyn rightly, he does not mention. In this, the last-named traveller found a staircase leading to subterranean apartments, as he thought, but nothing of interest was discovered. The general dimensions of the building (P) extend about 160 ft. from north to south, and 190 ft. from east to west. It exhibits ten portals in ruins, besides other remains; and there are traces of thirty-six columns, in six ranks of six each. The spot is covered with fragments, under which have been traced conveyances for water. To the west of the last-named building was another entirely in ruins: to the east of it are visible the remains of a fine staircase, much resembling that first described, and which, therefore, we do not think it necessary to particularise, more than we do the numberless fragments scattered over the whole area, which was equal to nearly thirty English acres! The ruins at Q are of portals. At R and S are tombs cut in the rock, of curious form, but evidently, from their character, the work of those who constructed the enormous pile of building of which we have already inserted a representation. Between the leading forms of the portals of these ruins, or porticoes, as Le Bruyn calls them, and those of the structures of Egypt, there is a very striking resemblance. On comparison of the two, it is impossible not to be struck with the large crowning hollowed member, which seems to have been common to the edifices on the banks of the Nile and those on the plain of Merdasht. In both, this member, forming, as it were, an entablature, is ornamented with vertical ribs or leaves, and the large fillet above the hollow appears equally in each. In the walls of the Persepolitan remains, there is perhaps less real massiveness than in those which were the works of the Egyptians; but the similarity of appearance between them points to the conjecture that, though neither might have been borrowed from the other, they are not many removes from one common parent. The an-

nexed diagram (*fig. 26.*) will give the reader some notion of the style of the architecture of

Fig. 26.

ARCHITECTURE OF PERSEPOLIS.

Persepolis. The diagram (*fig. 27.*) exhibits a specimen of a column and capital. *Fig. 28.* is a capital from one of the tombs. The walls forming the revêtement of the great esplanade are wonderfully perfect; and appear still capable of resisting equally the attacks of time and barbarism. The surface of the platform, generally, is unequal, and was of different levels: the whole seems to have been hewn from the mountain, from whence the marble has been extracted for constructing the edifices: hence the pavements appear masses of marble, than which nothing more durable or beautiful can be conceived. No cement appears to have been used, but the stones seem to have been connected by cramps, whose removal, however, has neither deranged the courses from which they have been removed, nor affected their nice fitting to each other; they are, indeed, so well wrought that the joints can scarcely be perceived, so close that the thinnest plate of metal could not be introduced between them.

FIG. 27. COLUMN AND CAPITAL.

FIG. 28. CAPITAL FROM A TOMB.

50. No person can look at the style of composition and details of Persepolis without a conviction of some intimate connection between the architects of Persia and those of Egypt.

FIG. 29. ARROW-HEADED CHARACTERS.

The principles of both are identical; and without inquiring into the exact date of the monument whose description we have just left, there is sufficient to convince us that the theory started in respect of the Cyclopean architecture, of the arts travelling in every direction from some central Asiatic point, is fully borne out; and that the Egyptian style had its origin in Asia. We are quite aware that conjectures, bearing a semblance of probability, have assigned the erection of this stupendous palace to Egyptian captives, at a comparatively late period, after the conquest of Egypt by

FIG. 30. NAKSHI RUSTAN.

Cambyses; but we think they are answered by the similarity of arrow-headed characters used therein to those of ancient Babylon, whereof an example is here given (*fig. 29.*) from one of the portals of Persepolis. A few miles to the south of Persepolis, the excavated hill of Nakshi Rustân (*fig. 30.*) presents a number of sculptured

tombs, the highest supposed to be coeval with Persepolis, and formed for the sepulture of the early kings of Persia. The lower tombs seem to have belonged to the Parthian Sassanide dynasties.

51. The present architecture of Persia much resembles that of other Mahometan countries. The city of Ispahan, in its prosperity, is said to have been surrounded by a wall twenty miles in circuit. When visited by Chardin, in 1666-7, the walls were so completely covered with houses as to be scarcely discernible; and he observes, that from whatever side the city is beheld it resembles a wood, where only domes are to be seen, with lofty slender towers attached to them. The houses are generally mean in external appearance: they commonly consist of a large square court surrounded with rooms of varying dimensions for different uses, the sides of the area being planted with flowers, and refreshed by fountains. Distinct from this is a smaller court, round which are distributed the apartments belonging to the females of the family; and almost every dwelling has a garden attached to it. The interior apartments of the richer classes are splendidly finished, though simply furnished. Those inhabited by the governor, public officers, and opulent merchants, may almost vie with palaces. Nearly all of them are constructed with sun-dried bricks, the public edifices only being built with burnt bricks: the roofs are mostly flat, having terraces, whereon the inhabitants sleep during several months of the year. According to the author above quoted, there were in his time within the walls 160 mosques, 48 colleges, 1802 caravanseras, 273 baths, 12 cemeteries, and 38,000 houses. But since that period the city has fallen into great ruin. The *Shah Meidan*, however (*figs. 31. and 32.*), or royal square, is still one of the

Fig. 31.

PLAN OF THE SHAH MEIDAN.

largest and finest in the world. It is 440 paces in length, and 160 in breadth. On its south side stands the royal mosque, a magnificent building, erected by Shah Abbas, in the

Fig. 32.

THE SHAH MEIDAN.

sixteenth century, and constructed of stone, covered with highly varnished bricks and tiles, whereon are inscribed sentences of the Koran. On another side of the Meidan is a Mahometan college called the Medresse Shah Sultan Hossein. The entrance is through a lofty portico decorated with twisted columns of Tabriz marble, leading through two brazen gates, whose extremities are of silver, and their whole surface sculptured and embossed with flowers,

and verses from the Koran. Advancing into the court, on the right side is a mosque, whose dome is covered with lacquered tiles, and adorned externally with ornaments of pure gold. This, and the minarets that flank it, are now falling into decay. The other sides of the square are occupied, one, by a lofty and beautiful portico, and the remaining two by small square cells for students, twelve in each front, disposed in two stories. In the city are few hospitals; one stands, however, beside the caravanserai of Shah Abbas, who erected both at the same time, that the revenue of the latter might support the proper officers of the hospital. That the reader may have a proper idea of one of these inns of the

East, if they may be so called, we have here given the plan of that just above named (*fig.*

Fig. 33.

CARAVANSERAI OF SHAH ABBAS.

marble, sculptured into four lions, so placed that the shafts stand on them. Mirrors are distributed on the walls in great profusion, and the ceiling is ornamented with gilt flowers. An arched recess leads from the apartment just described into a spacious and splendid hall, whose roof is formed into a variety of domes, decorated with painting and gilding. The walls are partly of white marble, and partly covered with mirrors, and are moreover decorated with six large paintings, whose subjects are the battles and royal fêtes of Shah Ismael and Shah Abbas the Great. Though of considerable age, the colours are fresh, and the gilding still brilliant. Adjoining the palace is the harem, erected but a few years ago. The bazaars are much celebrated; they consist of large wide passages, arched, and lighted from above, with buildings or stores on each side. One of these was formerly 600 geometrical paces in length, very broad and lofty. From these being adjacent to each other, a person might traverse the whole city sheltered from the weather. In Ispahan, we must not forget to notice that some fine bridges exist, which cross the river Zenderond.

## SECT. V.

### JEWISH ARCHITECTURE.

52. We are scarcely justified in giving a section, though short, to the architecture of the Jews, since the only buildings recorded as of that nation are the Temple of Jerusalem constructed by Solomon, and the house of the forest of Lebanon. The shepherd tribes of Israel, indeed, do not seem to have required such dwellings or temples as would lead them, when they settled in cities, to the adoption of any style very different from that of their neighbours. Whatever monuments are mentioned by them appear to have been rude, and have been already noticed in the section on Druidical and Celtic architecture. When Solomon ascended the throne, anxious to fulfil the wish his father had long entertained of erecting a fixed temple for the reception of the ark, he was not only obliged to send to Tyre for workmen, but for an architect also. Upon this temple a dissertation has been written by a Spaniard of the name of Villalpanda, wherein he, with consummate simplicity, urges that the orders, instead of being the invention of the Greeks, were the invention of God himself, and that Callimachus most shamefully put forth pretensions to the formation of the Corinthian capital which, he says, had been used centuries before in the temple at Jerusalem. The following account of the temple is from the sixth chapter of the First Book of Kings. Its plan was a parallelogram (taking the cubit at 1'824 ft., being the length generally assigned to it) of about 109½ ft. by 36½ ft., being as nearly as may be two thirds of the size of the church of St. Martin's in the Fields. In front was a pronaos, or portico, stretching through the whole front (36½ ft.) of the temple, and its depth was half its extent. The cell, or main body of the temple, was 54½ ft. deep, and the sanctuary beyond 36½ feet, the height of it being equal to its length and breadth. The height of the middle part, or cell, was 54½ ft.; and that of the portico the same as the sanctuary, — that is, 36½ ft., — judging from the height of the columns. In the interior, the body of the temple was surrounded by three tiers of chambers, to which there was an ascent by stairs; and the central part was open to the sky. The ends of the beams of the floors rested on corbels of stone, and were not inserted into the walls, which were lined with cedar, carved into

cherubims and palm trees, gilt. In the sanctuary two figures of cherubs were placed, whose wings touched each other in the centre, and extended outwards to the walls. These were 10 cubits high. In the front of the portico were two pillars of brass, which were cast by Hiram, "a widow's son of the tribe of Naphtali," whose "father was a man of Tyre," and who "came to king Solomon and wrought all his work." These two pillars of brass (1 *Kings*, vii. 14, 15.) were each 18 cubits high, and their circumference was 12 cubits; hence their diameter was 3·82 cubits. The chapters, or capitals, were 5 cubits high; and one of them was decorated with lilies upon a net-work ground, and the other with pomegranates. From the representation (*fig. 34.*) here given, the reader must be struck with their resemblance to the columns of Egypt with their lotus leaves, and sometimes net-work. In short, the whole description would almost as well apply to a temple of Egypt as to one at Jerusalem. And this tends, though slightly it is true, to show that the Phœnician workmen who were employed on the temple worked in the same style as those of Egypt.

Fig. 34.

53. The house of the forest of Lebanon was larger than the temple, having been 100 cubits in length, by 50 in breadth; it also had a portico, and from the description seems to have been similar in style.

54. *Phœnician Architecture.*—That part of the great nation of Asia which settled on the coasts of Palestine, called in scripture Canaanites, or merchants, were afterwards by the Greeks called Phœnicians. Sidon was originally their capital, and Tyre, which afterwards became greater than the parent itself, was at first only a colony. From what we have said in a previous section on the walls of Mycene, it may be fairly presumed that their architecture partook of the Cyclopean style; but that it was much more highly decorated is extremely probable from the wealth of a people whose merchants were princes, and whose traffickers were the honourable of the earth. Besides the verses of Euripides, which point to the style of Phœnician architecture, we have the authority of Lucian for asserting that it was Egyptian in character. Unfortunately all is surmise; no monuments of Phœnician architecture exist, and we therefore think it useless to dwell longer on the subject.

## SECT. VI.

### INDIAN ARCHITECTURE.

55. Whence the countries of India derived their architecture is a question that has occupied abler pens than that which we wield, and a long period has not passed away since the impression on our own mind was, that the monuments of India were not so old as those of Egypt. Upon maturer reflection, we are not sure that impression was false; but if the arts of a country do not change, if the manners and habits of the people have not varied, the admission of the want of high antiquity of the monuments actually in existence will not settle the point. The capitals and columns about Persepolis have a remarkable similarity to some of the Hindoo examples, and seem to indicate a common origin; indeed, it is our opinion, and one which we have not adopted without considerable hesitation, that though the existing buildings of India be comparatively modern, they are in a style older than that of the time of their erection. Sir William Jones, whose opinion seems to have been that the Indian temples and edifices are not of the highest antiquity, says (3rd Discourse), "that they prove an early connection between India and Africa. The pyramids of Egypt, the colossal statues described by Pausanias and others, the Sphinx and the Hermes Canis (which last bears a great resemblance to the Varáhavatár, or the incarnation of Vishnu in the form of a boar), indicate the style and mythology of the same indefatigable workmen who formed the vast excavations of Canárah, the various temples and images of Buddha, and the idols which are continually dug up at Gayá or in its vicinity. The letters on many of these monuments appear, as I have before intimated, partly of Indian and partly of Abyssinian or Ethiopic origin; and all these indubitable facts may induce no ill-grounded opinion that Ethiopia and Hindustan were peopled or colonised by the same extraordinary race." In a previous page (*fig. 27.*), the reader will find a Persepolitan column and capital; we place before him, in *fig. 35.*, an example from the Indra Subba which much resembles it in detail, and at the Nerta Chabei at Chillambaram are very similar examples. Between the styles of Persepolis and Egypt a resemblance will be hereafter traced, and to such an extent, that there seems no reasonable doubt of a common origin. The monuments of India may be divided into two classes, the *excavated* and *constructed*: the former being that where a building has been hollowed, or, as it were, quarried out of the rock; the latter, that built of separate and different sorts of materials, upon a regular plan, as may be seen in those buildings improperly called pagodas, which ornament the enclosures of the sacred edifices, of

Fig. 35. A COLUMN OF THE INDRA SUBBA.

which they are component parts. The class first named seems to have interested travellers more than the last, from the apparent difficulty of execution ; but on this account we are not so sure that they ought to create more astonishment than the constructed temple, except that, according to Daniel (*Asiat. Res.* vol. i.), they are hollowed in hard and compact granite.

56. The monuments which belong to the first class are of two sorts ; those actually hollowed out of rocks, and those presenting forms of *apparently* constructed buildings, but which are, in fact, rocks shaped by human hands into architectural forms. Of the first sort are the caves of Elephanta and Ellora ; of the last, the seven large pagodas of Mavalipowram. It will immediately occur to the reader that the shaping of rocks into forms implies art, if the forms be imposing or well arranged : so, if the hollowing a rock into well-arranged and well-formed chambers be conducted in a way indicating an acquaintance with architectural effect, we are not to assume that a want of taste must be consequent on the first sort merely because it cannot be called constructive architecture. And here we must observe, that we think the writer in the *Encyclopédie Méthodique* (art. Arch. Indienne) fails in his reasoning ; our notion being simply this, that as far as respects these monuments, if they are worthy to be ranked as works of art, the means by which they were produced have nothing to do with the question. It must, however, be admitted, that what the architect understands by ordonnance, or the composition of a building, and the proper arrangement of its several parts, points which so much engaged the attention of the Greeks and Romans, will not be found in Indian architecture as far as our acquaintance with it extends. Conjectures infinite might be placed before the reader on the antiquity of this species of art, but they would be valueless, no certain data, of which we are aware, existing to lead him in the right road ; and we must, therefore, be content with enumerating some of the principal works in this style. The caves at Ellora consist of several apartments ; the plan of that called the Indra Subba (*fig. 36.*) is here given, to show the species of plan which these places

57. The most celebrated excavated temple is that of Elephanta (*fig. 38.*), near Bombay,

of whose interior composition the reader may obtain a faint idea from the subjoined representation (*fig. 39.*). It is 130 ft. long, 110 ft. wide, and 14½ ft. high. The ceiling is flat, and is apparently supported by four ranks of columns, about 9 ft. high, and of a balustral form. These stand on pedestals, about two thirds the height of the columns themselves. A great portion of the walls is covered

with colossal human figures, forty to fifty in number, in high relief, and distinguished by a variety of symbols, probably representing the attributes of the deities

Fig. 38.

TEMPLE OF ELEPHANTA.

Fig. 39

INTERIOR OF THE TEMPLE OF ELEPHANTA.

whom they worshipped, or the actions of the heroes whom they represented. At the end of the cavern there is a dark recess, about 20 ft. square, entered by four doors, each flanked by gigantic figures. "These stupendous works," says Robertson, "are of such high antiquity, that, as the natives cannot, either from history or tradition, give any information concerning the time in which they were executed, they universally ascribe the formation of them to the power of superior beings. From the extent and grandeur of these subterraneous mansions, which intelligent travellers compare to the most celebrated monuments of human power and art in any part of the earth, it is manifest that they could not have been formed in that stage of social life where men continue divided into small tribes, unaccustomed to the efforts of persevering industry." Excavations similar to those we have named are found at Canaráh, in the Island of Salsette, near Bombay. In these there are four stories of galleries, leading in all to three hundred apartments. The front is formed by cutting away one side of the rock. The principal temple, 84 ft. long, and 40 ft. broad, is entered by a portico of columns. The roof is of the form of a vault, 40 ft. from the ground to its crown, and has the appearance of being supported by thirty pillars, octagonal in plan, whose capitals and bases are formed of elephants, tigers, and horses. The walls contain cavities for lamps, and are covered with sculptures of human figures of both sexes, elephants, horses, and lions. An altar, 27 ft. high and 20 ft. in diameter, stands at the further end, and over it is a dome shaped out of the rock. Though the sculptures in these caves are low in rank compared with the works of Greek and Etrurian artists, yet they are certainly in a style superior to the works of the Egyptians; and we infer from them a favourable opinion of the state of the arts in India at the period of their formation. "It is worthy of notice," observes the historian we have just quoted, "that although several of the figures in the caverns at Elephanta be so different from those now exhibited in the pagodas as objects of veneration, that some learned Europeans

have imagined they represent the rites of a religion more ancient than that now established in Hindostan; yet by the Hindoos themselves the caverns are considered as hallowed places of their own worship, and they still resort thither to perform their devotions, and honour the figures there, in the same manner with those in their own pagodas." Mr. Hunter, who in the year 1784 visited the place, considers the figures there as representing deities who are still objects of worship among the Hindoos. One circumstance justifying this opinion is, that several of the most conspicuous personages in the groups at Elephanta are decorated with the *zennar*, the sacred string or cord peculiar to the order of Brahmins, an authentic evidence of the distinction of casts having been established in India at the time when these works were finished.

Fig. 40. PAGODA OF CHILLAMBARAM.

58. The structure of the earliest Indian temples was extremely simple. Pyramidal, and of large dimensions, they had no light but that which the door afforded; and, indeed, the gloom of the cavern seems to have led them to consider the solemn darkness of such a mansion sacred. There are ruins of this sort at Deogur and at a spot near Tanjore, in the Carnatic. In proportion, however, to the progress of the country in opulence and refinement, their sacred buildings became highly ornamented, and must be considered as monuments exhibiting a high degree of civilisation of the people by whom they were erected. Very highly finished pagodas, of great antiquity, are found in different parts of Hindostan, and particularly in its southern districts, where they were not subjected to the destructive fury of Mahometan zeal. To assist the reader in forming a notion of the style of the architecture whereof we are treating, we here place before him a diagram (fig. 40.) of part of the pagoda at Chillambaram, near Porto Novo, on the Coromandel coast; one which is, on account of its antiquity, held in great veneration. The monument would be perhaps more properly described as a cluster of pagodas, enclosed in a rectangular space 1332 ft. in length, and 936 ft. in width, whose walls are 30 ft. in height, and 7 ft. in thickness, each side being provided with a highly decorated frustum of a pyramid over an entrance gateway. The large enclosure is subdivided into four subordinate ones, whereof the central one, surrounded by a colonnade and steps, contains a piscina or basin for purification. That on the southern side forms a cloister enclosing three contiguous temples called *Chabei*, lighted only by their doors and by lamps. The court on the west is also claustral, having in the middle an open portico, consisting of one hundred columns, whose roof is formed by large blocks of stone. The last is a square court with a temple and piscina, to which is given the name of the Stream of Eternal Joy. To the temple is attached a portico of thirty-six columns, in four parallel ranks, whose central intercolumniation is twice the width of those at the sides, and in the centre, on a platform, is the statue of the Bull Nundu. It is lighted artificially with lamps, which are kept constantly burning, and is much decorated with sculpture. The central inclosure, on its eastern side, has a temple raised on a platform, in length 224 ft., and in width 64 ft., having a portico in front, consisting of a vast number of columns 30 ft. high; at the end of it a square vestibule is constructed with four portals, one whereof in the middle leads to the sanctuary, named *Nerta Chabei*, or Temple of Joy and Eternity, the altar being at the end of it. The temple is much decorated with sculpture, representing the divinities of India. The pilaster fig. 41. is placed at the sides of the door of the *Nerta Chabei*, and is extremely curious; but the most singular object about the building is a chain of granite carved out of the rock, attached to the pilasters, and supported at four other points in the face of the rock so as to form festoons. The links are about 3ft. long, and the whole length of the chain is 146 ft. The pyramids

Fig. 41. PILASTER FROM THE NERTA CHABEI.

above mentioned, which stand over the entrances of the outer enclosure, rise from rectangular bases, and consist of several floors. The passage through them is level with the ground.

59. A very beautiful example of the Indian pagoda exists at Tanjore, which we here insert (*fig. 42.*).

60. One of the largest temples known is that on the small island Seringham, near Trichinopoly, on the Coromandel coast. It is situate about a mile from the western extremity of the island, and is thus described by Sonnerat. It is composed of seven square enclosures, one within the other, the walls

These enclosures are 350 ft. distant from one another, and each has four large gates with a high tower; which are placed, one in the middle of each side of the enclosure, and opposite to the four cardinal points. The outward wall is near four miles in circumference, and its gateway to the south is ornamented with pillars, several of which are simple stones, 33 ft. long, and nearly 5 ft. in diameter; and those which form the roof are still larger. In the inmost inclosures are the chapels. About half a mile to the east of Seringham, and nearer to the river Caveri than the Coleroon, is another large pagoda, called Jembikisma, but this has only one enclosure. The extreme veneration in which Seringham is held arises from a belief that it contains that identical image of the god Vishnu which used to be worshipped by Brahma.

61. We shall conclude this section with some observations on Tchoultry (or Iun) at Madurah (*fig. 43.*). Its effect is quite theatrical, and its perfect symmetry gives it the appearance of a work of great art, and of greater skill in composition than most other Indian works. Yet an examination of the details, and particularly of the system of corbelling over, destroys the charm which a first glance at it creates. In it, the ornaments which in Grecian architecture are so well applied and balanced, seem more the work of chance than of consideration. We here insert an external view

of the temple at this place (*fig. 44.*). The essential differences between Indian and Egyptian architecture, in connection with the sculpture applied to them, have been well given in the *Encyclopédie Méthodique*, and we shall here subjoin them. In Egypt, the principal forms of the building and its parts preponderate, inasmuch as the hieroglyphics with which they are covered never interfere with the general forms, nor injure the effect of the whole; in India, the principal form is lost in the ornaments which divide and decompose it. In Egypt, that which is essential predominates; in India, you are lost in the multitude of

Fig. 42. PAGODA AT TANJORE.

whereof are 25 ft. high, and 4 ft. thick.

Fig. 43. TCHOULTRY AT MADURAH.

of the temple at this place (*fig. 44.*).

Fig. 44. TEMPLE AT MADURAH.

accessories. In the Egyptian architecture, even the smallest edifices are grand; in that of India, the infinite subdivision into parts gives an air of littleness to the largest buildings. In Egypt, solidity is carried to the extreme; in India, there is not the slightest appearance of it.

## SECT. VII.

### EGYPTIAN ARCHITECTURE.

62. We propose to consider the architecture of Egypt — First, in respect of the physical, political, and moral causes which affected it. Secondly, in respect of its analysis and development. Thirdly, and lastly, in respect of the taste, style, and character which it exhibits.

63. I. In our introduction, we have alluded to the three states of life which even in the present day distinguish different nations of the earth — hunters, shepherds, and agriculturists; in the second class whereof are included those whose subsistence is on the produce of the waters, which was most probably the principal food of the earliest inhabitants of Egypt. Seated on the banks of a river whose name almost implies fertility, they would have been able to live on the supply it afforded for a long period before it was necessary to resort to the labours of agriculture. In such a state of existence nothing appears more probable than that they should have availed themselves of the most obvious shelter which nature afforded against the extremes of heat and cold, namely, the cavern; which, consisting of tufo and a species of white soft stone, was easily enlarged or formed to meet their wants. Certain it is, that at a very early period the Egyptians were extremely skilful in working stone, an art which at a later time they carried to a perfection which has never been surpassed. As the Tyrians, Sidonians, and other inhabitants of Palestine were, owing to the material which their cedar forests afforded, dexterous in joinery, so the Egyptians received an impulse in the style of their works from an abundance of the stone of all sorts which their quarries produced. Subterranean apartments, it will be said, are found in other countries; but they will mostly, India excepted, be found to be the remains of abandoned quarries, exhibiting no traces of architecture, nor places for dwelling. Egypt, on the contrary, from time immemorial, was accustomed to hollow out rocks for habitation. Pliny (lib. xxxvi. c. 13.) tells us, that the great Labyrinth consisted of immense excavations of this sort. Such were the subterranean chambers of Biban el Melook, those which have in the present day received the name of the Labyrinth, and many others, which were not likely to have been tombs. When the finished and later monuments of a people resemble their first essays, it is easy to recognise the influential causes from which they result. Thus, in Egyptian architecture, every thing points to its origin. Its simplicity, not to say monotony, its extreme solidity, almost heaviness, form its principal characters. Then the want of profile and paucity of members, the small projection of its mouldings, the absence of apertures, the enormous diameter of the columns employed, much resembling the pillars left in quarries for support, the pyramidal form of the doors, the omission of roofs and pediments, the ignorance of the arch (which we believe to have been unknown, though we are aware that a late traveller of great intelligence is of a different opinion),—all enable us to recur to the type with which we have set out. If we pursue this investigation, we do not discover timber as an element in Egyptian compositions, whilst in Grecian architecture, the types certainly do point to that material. It is not necessary to inquire whether the people had or had not tents or houses in which timber was used for beams or for support, since the character of their architecture is specially influenced by the exclusive use of stone as a material; and however the form of some of their columns may not seem to bear out the hypothesis (such, for instance, as are shaped into bundles of reeds with imitations of plants in the capitals), all the upper parts are constructed without reference to any other than stone construction. It is, moreover, well known that Egypt was extremely bare of wood, and especially of such as was suited for building.

64. The climate of Egypt was, doubtless, one great cause of the subterranean style, as it must be in the original architecture of every nation. Materials so well adapted to the construction it induced, furnishing supports incapable of being crushed, and single blocks of stone which dispensed with all carpentry in roofs or coverings, a purity of air and evenness of temperature which admitted the greatest simplicity of construction from the absence of all necessity to provide against the inclemency of seasons, and which permitted the inscription of hieroglyphics even on soft stone without the fear of their disappearance,—all these concurred in forming the character of their stupendous edifices, and stimulated them in the development of the art.

65. The monarchical government, certainly the most favourable to the construction of great monuments, appears to have existed in Egypt from time immemorial. The most

important edifices with which history or their ruins have made us acquainted, were raised under monarchies; and we scarcely need cite any other than the ruins of Persepolis, of which an account is given in a previous section, to prove the assertion: these, in point of extent, exceed all that Egypt or Greece produced. Indeed, the latter nation sought beauty of form rather than immense edifices; and Rome, until its citizens equalled kings in their wealth, had no monuments worthy to be remembered by the historian, or transmitted as models to the artist.

66. Not the least important of the causes that combined in the erection of their monuments was the extraordinary population of Egypt: and though we may not perhaps entirely rely on the wonderful number of twenty thousand cities, which old historians have said were seated within its boundaries, it is past question that the country was favourable to the rearing and maintenance of an immense population. As in China at the present day, there appears in Egypt to have been a redundant population, which was doubtless employed in the public works of the country, in which the workman received no other remuneration than his food.

67. The Egyptian monarchs appear to have gratified their ambition as much in the provision for their own reception after this life as during their continuance in it. If we except the Memnonium, and what is called the Labyrinth at Memphis, temples and tombs are all that remain of their architectural works. Diodorus says, that the kings of Egypt spent those enormous sums on their sepulchres which other kings expend on palaces. They considered that the frailty of the body during life ought not to be provided with more than necessary protection from the seasons, and that the palace was nothing more than an inn, which at their death the successor would in his turn inhabit, but that the tomb was their eternal dwelling, and sacred to themselves alone. Hence they spared no expense in erecting indestructible edifices for their reception after death. Against the violation of the tomb it seems to have been a great object with them to provide, and doubts have existed on the minds of some whether the body was, after all, deposited in the pyramids, which have been thought to be enormous cenotaphs, and that the body was in some subterraneous and neighbouring spot. Other writers pretend that the pyramids were not tombs, assigning to them certain mystic or astronomical destinations. There are, however, too many circumstances contradictory of such an assumption to allow us to give it the least credit; and there is little propriety in calling them sepulchral monuments, whether or not the bodies of the monarchs were ever deposited in them. The religion of Egypt, though not so fruitful, perhaps, as that of Greece in the production of a great number of temples, did not fail to engender an abundant supply. The priesthood was powerful and the rites unchangeable: a mysterious authority prevailed in its ceremonies and outward forms. The temples of the country are impressed with mystery, on which the religion was based. Here, indeed, Secresy was deified in the person of Harpocrates; and, according to Plutarch (*De Iside*), the sphinx, which decorated the entrances of their temples, signified that mystery and emblem were engraven on their theology. Numerous doors closed the succession of apartments in the temples, leaving the holy place itself to be seen only at a great distance. This was of little extent, containing merely a living idol, or the representation of one. The larger portion of the temple was laid out for the reception of the priests, and disposed in galleries, porticoes, and vestibules. With few and unimportant variations, the greatest similarity and uniformity is observable in their temples, in plan, in elevation, and in general form, as well as in the details of their ornaments. In no country was the connection between religion and architecture closer than in Egypt, and as the conceptions and execution in architecture are dependent on the other arts, we will here briefly examine the influence which the religion of the country had upon them.

68. Painting and sculpture are not only intimately connected with architecture through the embellishments they are capable of affording to it, but are handmaids at her service in what depends upon taste, upon the principles of beauty, upon the laws of proportion, upon the preservation of character, and in various other respects. Nature, in one sense, is the model upon which architecture is founded; not as a subject of imitation, but as presenting for imitation principles of the harmony, proportion, effect, and beauty, for which the arts generally are indebted to nature. We think it was Madame de Staël who said that architecture was frozen music. Now, though in architecture, as in the other arts, there is no sensible imitation of nature, yet by a study of her mode of operating, it may be tempered and modified so as to give it the power of language and the sublimity of poetry. In respect of the connection of the art with sculpture, little need be said: in a material light, architecture is but a sculptured production, and its beauty in every country is in an exact ratio with the skill which is exhibited in the use of the chisel. Facts, however, which are worth more than arguments, prove that as is the state of architecture in a country, so is that of the other arts. Two things prevented the arts of imitation being carried beyond a certain point in the country under our consideration; the first was political, the other religious. The first essays of art are subjects of veneration in all societies; and when, as in Egypt, all change was forbidden, and a constant and inviolable respect was entertained for that which had existed be-

fore, when all its institutions tended to preserve social order as established, and to discourage and forbid all innovation, the duration of a style was doomed to become eternal. Religion, however, alone, was capable of effecting the same object, and of restraining within certain bounds the imitative faculty, by the preservation of types and primitive conventional signs for the hieroglyphic language, which, from the sacred purposes for which it was employed, soon acquired an authority from which no individual would dare to deviate by an improvement of the forms under which it had appeared. Plato observes, that no change took place in painting among the Egyptians; but that it was the same, neither better nor worse, than it had been ages before his time. *Σκοπὸν δ' εὐρησεῖς αὐτοὶ τὰ μυριοστόν ἐτος γεγραμμένα, ἢ τετυπωμένα (οὐχ ὥς ἐπὶ εἰπεῖν μυριοστόν, ἀλλ' οὕτως) τῶν νῦν δεδημιουργημένων οὐτε τι καλλίονα, οὐτ' αἰσχίω, τὴν αὐτὴν δὲ τέχνην ἀπειργασμένα.* — *De Legibus*, lib. ii.

69. Uniformity of plan characterises all their works; they never deviated from the right line and square. "Les Egyptiens," observes M. Caylus "ne nous ont laissé aucun monument public dont l'elevation ait été circulaire." The uniformity of their elevations is still more striking. Neither division of parts, contrast, nor effect is visible. All this necessarily resulted from the political and religious institutions whereof we have been speaking.

70. II. In analysing the architecture of Egypt, three points offer themselves for consideration, — construction, form, and decoration. In construction, if solidity be a merit, no nation has equalled them. Notwithstanding the continued effect of time upon the edifices of the country, they still seem calculated for a duration equally long as that of the globe itself. The materials employed upon them were well adapted to insure a defiance of all that age could effect against them. The most abundant material is what the ancients called the Thebaic granite. Large quarries of it were seated near the Nile in Upper Egypt, between the first cataract and the town of Assouan, now Syene. The whole of the country to the east, the islands, and the bed of the Nile itself, are of this red granite, whereof were formed the obelisks, colossal statues, and columns of their temples. Blocks of dimensions surprisingly large were obtained from these quarries. Basalt, marble, freestone, and alabaster were found beyond all limit compared with the purposes for which they were wanted.

71. We have already observed, that Egypt was deficient in timber, and especially that sort proper for building. There are some forests of palm trees on the Lybian side, near Dendera (Tentyris); but the soil is little suited to the growth of timber. Next in quantity to the palm is the acacia; the olive is rare. With the exception of the palm tree, there is none suited for architectural use. The oak is not to be found; and that, as well as the fir which the present inhabitants use, is imported from Arabia. Diodorus says, that the early inhabitants used canes and reeds interwoven and plastered with mud for their huts; but he confines this practice to the country away from towns, in which, from fragments that have been found, we may infer that brick was the material in most common use.

72. Bricks dried in the sun were employed even on large monuments; but it is probable that these were originally faced either with stone or granite. The pyramids described by Pocock, called Ktoubé el Meuschich, are composed of bricks, some of which are  $13\frac{1}{2}$  in. long,  $6\frac{1}{2}$  in. wide, and 4 in. thick; others 15 in. long, 7 in. wide, and  $4\frac{1}{2}$  in. thick. They are not united by cement, but in some instances cements of a bituminous nature were employed, and in others a mortar composed of lime or plaster and sand, of which it would seem that the second was exceedingly powerful as well as durable.

73. The Egyptians arrived at the highest degree of skill in quarrying and working stone, as well as in afterwards giving it the most perfect polish. In their masonry they placed no reliance on the use of cramps, but rather on the nice adjustment of the stones to one another, on the avoidance of all false bearings, and the nice balance of all overhanging weight. Of their mechanical skill the reader will form some idea by reference to volume iii. p. 328. of Wilkinson's *Manners and Customs of the Ancient Egyptians*, from a representation in a grotto at El Bersheh. A colossus on a sledge is therein pulled along by 172 men, but none of the mechanical powers seem to be called in to their assistance. "The obelisks," says Mr. Wilkinson, "transported from the quarries of Syene to Thebes and Heliopolis, vary in size from 70 to 93 ft. in length. They are of one single stone; and the largest in Egypt, which is that at the great temple at Karnak, I calculate to weigh about 297 tons. This was brought about 138 miles from the quarry to where it now stands; and those taken to Heliopolis passed over a space of 800 miles." Two colossi (one of them is the vocal Memnon), each of a single block 47 ft. in height, and containing 11,500 cubic feet, are carved from stone not known within several days' journey of the place; and at the Memnonium is a colossal statue, which, when entire, weighed 887 tons. We consider, however, the raising of the obelisks a far greater test of mechanical skill than the transport of these prodigious weights; but into the mode they adopted we have no insight from any representations yet discovered. We can scarcely suppose that in the handling of the weights whereof we have spoken, they were unassisted by the mechanical powers, although, as we have observed, no representations to warrant the conjecture have been brought to light.

74. In the construction of the pyramids it is manifest they would serve as their own scaffolds. The oldest monuments of Egypt of which we below give a view, and a section of that of the largest, called of Cheops (*fig. 45.*), are the pyramids at Gizeh, to the north of Memphis. Mr. Wilkinson supposes them to have been erected by Suphis and Jeusuphis his brother, 2120 years B. C., that is, previous by nearly 400 years to the entrance of Joseph into Egypt; but the same author admits that, previous to the reign of Osirtasen, 1740 B. C., there is nothing to guide any one with certainty as to dates. The edifices (*fig. 46.*), however, more commonly known by the names of Cheops, Cephrenes, and Mycerinus, are extraordinary for their size and the consequent labour bestowed upon them; but as works of the art they are of no further importance than being a link in the chain of its history. They are constructed of stone from the neighbouring mountains, and are in steps, of which in the largest there are two hundred and eight, varying in height from  $2\frac{1}{2}$  ft. (French) to 4 ft., decreasing in height as they rise towards the summit. Their width diminishes in the same proportion, so that a line drawn from the base to the summit touches the edge of each step. So great a

FIG. 45. SECTION OF PYRAMID OF CHEOPS.

Fig. 46. PYRAMIDS OF GIZEH.

difference in the measures by different authors appears, that we here subjoin those of the pyramid of Cheops:—

Authors.	Length of base.	No. of steps.	Height.	Authors.	Length of base.	No. of steps.	Height.
Herodotus	800 Gr. ft.	—	852 Eng. ft.	Thevenot	727 Eng. ft.	208	554 Eng. ft.
Strabo	600 —	—	666 —	Niebuhr	751 —	—	469 —
Diodorus	700 —	—	639 —	Chavannes	751 —	—	498 —
Sandys	300 paces	—	—	Mallet	—	208	—
Bellonius	324 —	—	—	Pocock	—	212	—
Graves	693 Eng. ft.	207	499 —	Belon	—	250	—
Le Bruyn	750 —	—	656 —	French Engineers	—	—	477 —
Prosper Alpinus	799 —	—	666 —				

Mr Perring, a recent traveller, in respect of the proportions of the great pyramid, has endeavoured to prove that the unit of Egyptian measurement is an ell equal to 1·713 English feet, and that it is expressed a certain number of times without remainder in a correct measurement of the pyramids of Gizeh. Thus, he says, the perpendicular height of the great pyramid is exactly 280 of such ells, the base 448; and that  $\frac{1}{2}$  base : perpendicular height :: slant height :  $\frac{1}{2}$  base. Upon the top thereof is a platform 32 ft. square, consisting of nine large stones, each about a ton in weight, though inferior in that respect to others in the edifice, which vary from 5 ft. to 30 ft. in length, and from 3 ft. to 4 ft. in height. From this platform Dr. Clarke saw the pyramids of Saccara to the south, and on the east of them smaller monuments of the same kind nearer to the Nile. He remarked, moreover, an appearance of ruins which might be traced the whole way from the pyramids of Gizeh to those of Saccara, as if the whole had once constituted one great city. The stones of the platform are soft limestone, a little harder and more compact than what in England is called *clunch*. The

Fig. 47. ENTRANCE TO THE SECOND PYRAMID.

pyramids are built with common mortar externally, but no appearance of mortar can be discerned in the more perfect parts of the masonry. The faces of the pyramid are directed to the four cardinal points. The entrance is in the north front, and the passage to the central chamber is shown on the preceding section. That in the pyramid of Cephrenes (*fig. 47.*) is thus described by Belzoni:—The first passage is built of granite, the rest are cut out of the natural sandstone rock which rises above the level of the basis of the pyramid. This passage is 104 ft. long, 4 ft. high, and 3 ft. 6 in. wide; descending at an angle of 26 degrees: at the bottom is a porteculis, beyond which is a horizontal passage

of the same height as the first, and at the distance of 22 ft. it descends in a different direction, leading to some passages below. Hence it re-ascends towards the centre of the pyramid by a gallery 84 ft. long, 6 ft. high, and 3 ft. 6 in. wide, leading to a chamber also cut out of the solid rock. The chamber is 46 ft. in length, 16 feet wide, and 23 ft. 6 in. in height, and contained a sarcophagus of granite 8 ft. long, 3 ft. 6 in. wide, and 2 ft. 3 in. deep in the inside. Returning from the chamber to the bottom of the gallery a passage descends at an angle of 26 degrees to the extent of 48 ft. 6 in., when it takes a horizontal direction for a length of 55 ft.; it then again ascends at the same angle and proceeds to the base of the pyramid, where another entrance is formed from the outside. About the middle of the horizontal passage there is a descent into another chamber, which is 32 ft. long, 10 ft. wide, and 8 ft. 6 in. high. The dimensions of this pyramid, as given by Denon, are a base of 655 ft. and a height of 398 ft. Those of the pyramid of Mycerinus are a base of 280 ft., and a height of 162 ft. The pyramids of Saccara, which are as many as twenty in number, vary in form, dimensions, and construction. They extend five miles to the north and south of the village of Saccara. Some of them are rounded at the top, and resemble hillocks cased with stone. One is constructed with steps like that of Cheops. They are six in number, each 25 ft. high, and 11 ft. wide. The height of one in the group is 150 ft. Another, built also in steps, is supposed to be as high as that of Cheops. The stones whereof they are composed are much decayed, and more crumbling than those of Gizeh; hence they are considered older. One of them is formed of unburnt bricks, containing shells, gravel, and chopped straw, and is in a very mouldering state. About 300 paces from the

Fig. 48.

THE SPHINX.

second pyramid stands the extraordinary gigantic statue of the Sphinx (*fig. 48.*), whose length from the fore-part to the tail has been found to be 125 ft. Belzoni cleared away the sand, and found a temple held between the legs and another in one of its paws. According to Denon, the antiquity of the Egyptian temples may be comparatively determined from their size; the larger ones being posterior to the smaller. Since, however, the wonderful insight we have obtained into the meaning of the hieroglyphics, more accurate information than we before possessed may be gained on that point by reference to Mr. (now Sir Gardiner) Wilkinson's works on Egypt and Thebes. A spirit of simplicity, grandeur, and solidity reigns through the whole of them, and every precaution seems to have been taken to render them eternal. The walls by which they are enclosed are found sometimes 26 ft. in thickness, and those of the entrance gate of a temple at Thebes are as much as 53 ft. thick at their base, and are composed of blocks of enormous size. The masonry employed is that called by the Greeks *empletum* (*εμπλεκτον*), all filling in of an inferior or rubble work being discarded. They are masses of nicely squared and fitted stones, and are built externally with a slope like the walls of a modern fortification. The columns are absolutely necessary for the support of the ceilings, which consist of large blocks of stone, and are therefore of few diameters in height. Sometimes they are in a single piece, as at Thebes and Tentyris. The stones of which the ceilings are composed are usually, according to Pococke, 14 ft. long, and 5½ ft. in breadth, but some run much larger.

75. Before adverting to the form and disposition of the Egyptian temple, we think it here necessary to notice the recent discovery of an arch in a tomb at Saccara, said to be of the time of Psammetichus II., and of one also at Thebes in the remains of a crude brick pyramid. (See *Wilkinson's Customs of the Ancient Egyptians*, vol. iii. p. 263. 321.) That exhibited in the tomb of Saccara, from the vignette given, is clearly nothing but a lining of the rock, and is, if truly represented in the plate, incapable of bearing weight, which is the office of an arch. That, however, at Thebes, to which Mr. W. assigns the date of 1500 B.C., with every respect for his great information on the subject, and with much deference to his judgment, not having ourselves seen it, we cannot easily believe to be of such antiquity. Its appearance is so truly Roman, that we must be permitted to doubt the truth of his conjecture. We are, moreover, fortified in the opinion we entertain by the principles on which the style of Egyptian architecture is founded, which are totally at variance with the use of the arch. We have ventured to transfer this (*fig. 49.*) to our pages, that the reader may form a judgment on the subject, as well as ourselves. We will only add, that the reasons assigned by Mr. W. for the Egyptians not preferring such a mode of construction as the arch, because of the difficulty of repairing it when injured, and the consequences attending the decay of a single block, are not of any weight with us, because, practically, there is an easy mode of accomplishing such repair. And, again, the argument that the superincumbent weight applied to an arch in such a case as that before

us will not hold good, inasmuch as the balance on the back of each course would almost preserve the opening without any arch at all.

FIG. 49. ARCH AT THREE.

of porticoes, courts, vestibules, galleries, apartments, communicating with each other, and surrounded with walls. Strabo, in his 17th book, thus describes the temples in question. "At the entrance of the consecrated spot the ground is paved to the width of 100 ft. (*πλεθρον*) or less, and in length three or four times its width, and in some places even more. This is called the court (*δρομος*, course); thus Callimachus uses the words —

Ὁ δρόμος ἵερὸς αὐτοῦς Ἀνευῶδες.

Throughout the whole length beyond this on each side of the width, are placed sphinxes of stone, 20 cubits or more distant from one another, one row being on the right, and the other on the left. Beyond the sphinxes is a great vestibule (*προπυλαιον*), then a further one, and beyond this another. The number, however, of the sphinxes, as of the vestibules, is not always the same, but varies according to the length and breadth of the course. Beyond

FIG. 50. PLAN OF TEMPLE AT APOLLONOPOLIS MAGNA.

the vestibules (*προπυλαια*) is the temple (*νεως*), having a very large porch (*προναος*), which is worthy to be recorded. The chapel (*σηκος*) is small, and without a statue; or, if there be one, it is not of human form, but that of some beast. The porch on each side has a wing (*πτερα*); these consist of two walls as high as the temple itself, distant from each other at the bottom a little more than the width of the foundations of the temple, then they incline towards each other, rising to the height of 50 or 60 cubits. These walls are sculptured with large figures, similar to those which are to be seen in the works of the Etruscans and ancient Greeks." This account is not at all exaggerated, as we shall immediately show by the introduction in this place of the plan, section, and elevation of the celebrated temple at Apollonopolis Magna, between Thebes and the first cataract, which, though, as we learn from the deciphering in these days, the hieroglyphics upon it are not of the time of the Pharaohs, seems admirably calculated to give the reader almost all the information necessary for understanding the subject. This will, moreover, so much more fully explain it than words, that we shall not need to do more than afterwards come to some recital of the details.

77. This edifice, seated near Edfou, about twenty miles south of Thebes, is one of the largest in Egypt, and is comparatively in good preservation. Its form is rectangular, and its general dimensions 450 ft. by 140 ft. (*fig. 50.*) In the centre of one of the short sides is the entrance, which consists of two buildings, each 100 ft. long, and 32 ft. in width; both pyramidal in form, and lying in the same direction, but separated by a passage 20 ft. in width, with a doorway at each extremity. This passage conducts us to a quadrangle 140 ft. long, and 120 ft. wide, flanked by twelve columns on each side, and eight more on the entrance side, all standing a few feet within the walls, and thus forming a colonnade round three sides covered by a flat roof. A view of a portion of it is given in *fig. 54.* At the further end of the quadrangle (which rises by corded steps) opposite to the entrance, is a portico extending the whole breadth of the quadrangle, and 45 ft. in depth. It has three ranks of columns, containing six in each rank, is covered by a flat roof, and is enclosed by walls on three sides, the fourth, or that opposite the entrance,

being open. This is, however, closed breast high by a species of pedestals half inserted in the columns, and in the central intercolumniation a doorway is constructed with piers, over which are a lintel and cornice cut through. From this portico a doorway leads to an inner vestibule, in which are three ranks of four columns each, smaller than those first described, but distributed in the same way. Beyond this, in Cousin's plan, are sundry apartments, with staircases and passages, whereof the smaller central one was

Fig. 51.

LONGITUDINAL SECTION OF TEMPLE AT APOLEONOPOLIS.

doubtless the cell. *Fig. 51.* is a longitudinal section. *Fig. 52.* is the elevation. We

Fig. 52.

ELEVATION.

Fig. 53.

VIEW OF THE TEMPLE.

may here add, that there is so little difference between the earlier and later specimens of Egyptian architecture, that though, as we have hinted, this is of the latter, it

Fig. 54.

VIEW OF THE INTERIOR.

will convey a pretty correct knowledge of all. The general appearance of the temple is given in *fig. 53.*, and a view of the interior in *fig. 54.* The plan of the Egyptian temple is always uniform, symmetrical, and rectangular. Its most brilliant feature is the great number of columns employed, in which is displayed a prodigality unapproached by any other nation. This, however, was induced by the necessity for employing blocks of stone for the ceilings or roofs. The greatest irregularity occurring in any of the plans known, is in that at the island of Philæ (see *fig. 55.*), and it

Fig. 55.

TEMPLE OF PHILÆ.

is very evident that the cause was the shape of the ground on which it is placed. The intercolumniations were very small, rarely exceeding a diameter, or one diameter and a half of the column. We know of no specimens of peripteral temples similar to those of Greece, that is, those in which the cell is surrounded by columns. In the elevations of those of Egypt, the spirit and character of their architecture is more particularly developed. But they are monotonous. The repetition of the same forms is carried to the utmost pitch of tolerance. The pyramidal form prevails in all the combinations, whether in walls, doors, general masses, or details. In considering the principal parts of the elevations, the first feature that presents itself is the column, which we will notice without its attendant base and capital. If it were possible to establish a system relative to their invention and subsequent perfection, we might easily arrange them in distinct classes, principally as respects their decoration; but as far as regards general form, the Egyptian column may be reduced to two varieties, the circular and polygonal. The first are of two sorts. Some are found quite plain or smooth, but ornamented with hieroglyphics (see *fig. 56.*). Some

are composed with ranges of horizontal circles, and look like an assemblage of bundles of rods tied together at intervals. The only difference among those columns which are circular and plain is in their having hieroglyphics, or not. Of the second sort there are many varieties, of which we here present three specimens (*fig. 57.*). They have the appearance of being bound together by hoops, like barrels. These are usually in three rows with four or five divisions in each; but these arrangements seem to have been subject to no certain laws. The species of columns in question is certainly curious, and appears based upon the imitation of stems of trees bound together, so as out of a number to form one strong post. It seems scarcely possible that they could have had their origin in mere whim or caprice. Many polygonal columns are to be found in Egypt. Some square specimens are to be seen in the grottoes at Thebes cut out of the rock itself. Similar examples occur at the entrance of the sanctuary of a temple in the same city. Hexagonal ones are described by Norden, and Pocock mentions one of a form triangular on the plan. We do not at present remember any fluted specimen, except in the tombs of Beni-Hassan, of which a representation will be given in the section on Grecian architecture. Their character is shortness and thickness. They vary from three to eleven feet in diameter, the last dimension being the largest diameter that Pocock observed, as in height the tallest was forty feet. Such were some of those he measured at Carnac and Luxor, but this he gives only as an approximation from the circumstance of so much of them being buried in the earth.

78. Pilasters, properly so called, are not found in Egyptian architecture. The base of the column, when it appears, is extremely simple in its form. Among the representations in Denon's work is one in which the base is in the shape of an inverted ogee. It belongs to a column of one of the buildings at Tentyris.

79. In their capitals, the Egyptians exhibited great variety of form. They may, however, be reduced to three species,—the square, the vase-formed, and the swelled. The first (*fig. 58.*) is nothing more than a simple abacus, merely placed on the top of the shaft of the column, to which it is not joined by the intervention of any moulding. This abacus is, however, sometimes high enough to admit of a head being sculptured thereon, as in the annexed block. It does not appear, as in Grecian architecture, that in that of Egypt differently proportioned and formed columns had different capitals assigned to them. The notion of imparting expression to architecture by a choice of forms of different nature, and more or less complicated according to the character of an order, was unknown in Egypt. It was an architectural language which the people knew not. The vase-shaped capital (*fig. 59.*) is variously modified: sometimes it occurs quite plain; in other cases it is differently decorated, of which we here give two examples. It certainly has all the appearance of having afforded the first hint for the bell of the Corinthian capital. The third or swelled capital is also found in many varieties; but if the form be not founded on that of the bud of a tree, we scarcely know wherein its original type is to be

sought. Two examples of it are here appended.

80. The entablature, for such (however unlike it be to the same thing in the architecture of Greece) we suppose we must call the massive loading placed on the walls and columns of ancient Egypt, is very little subdivided. The upper part of it, which we may call the cornice, projects considerably, having a large concave member, in some cases consisting of ornaments representing a series of reeds parallel to each other from top to bottom; in other cases in groups of three or six in a group, the intervals between them being sculptured with winged globes, as on the portico of the temple at Tentyris, given in *fig. 60.* Sculptures of animals, winged globes, and scarabæi, are the almost constant decorations placed on what may be called the architrave of the Egyptian temple. Of the winged globe, usually found on the centre of it, as also of the great concave cornice, *fig. 61.* is a representation.

We close our observations on the cornices of the Egyptian temple by requesting the reader, if he have the smallest doubt on the common origin of the archi-

Fig. 60. ENTABLATURE.

Fig. 61. WINGED GLOBE. A drawing of a winged globe, a common decorative element in Egyptian architecture, featuring a central circular motif with radiating lines and a pair of large, spread wings.

Fig. 61.

WINGED GLOBE.

tures of Egypt and Persepolis, to refer to *fig. 26.*, where he will find a precisely similar use of the great cavetto which crowned the buildings of both countries. The writer who, in the *Description Abrégée des Monumens de la Haute Egypt*, has found that this great curve is borrowed from the bending leaves of the palm tree, has mistaken the elements of decoration for substantial constructive art, and has forgotten that the first object follows long after the latter. But we doubt if he really meant what his words import. The ceilings of Egypt are invariably monotonous. The non-use of the arch, whereon we have touched in a preceding page, and the blocks of stone which the country afforded, allowed little scope for display of varied form. In the colonnades of the country, architraves of stone rest on the columns (see *fig. 54.*), on which transversely are placed those which actually form the ceilings, just like the floor boards of a modern economical English building. On them are often found some of the most interesting representations that are in existence: we allude to those of the zodiacal constellations disposed circularly about the centre of the apartments in which they are placed. Though nothing has been deduced from these to satisfy us on the date of their continent buildings, they are not the less unworthy of further investigation, which, however, it is not our province here to pursue.

81. The gates and portals of the Egyptian temples were either placed, as at Carnac

Fig. 62. EGYPTIAN PORTAL AT LUXOR.

and Luxor (*figs. 62. and 63.*), in masses of masonry, or between columns, as already noticed, inclined upwards, having generally a reed moulding round them, and the whole crowned with a large cavetto. They were plentifully covered with hieroglyphics; frequently fronted by a pair of obelisks; and on their sides were placed staircases of very simple construction, leading to platforms on their summits. It is now difficult to account for the extraordinary labour bestowed on these masses of masonry. More than pictorial effect must have been the motive. The reader will, by turning back to *fig. 52.*, be equally surprised with ourselves when he contemplates, in the gateway at the Temple of Apollinopolis Magna, such vast efforts developed on so apparently minor a point.

Fig. 63. EGYPTIAN PORTAL AT CARNAC.

The masses in these are always pyramidal, and bear great resemblance to the gates of modern fortifications. Sometimes they are extremely simple, and do not rise so high as the adjacent buildings which flank them. Their thickness is enormous, some of them extending to the extraordinary depth of fifty feet.

82. Windows were not frequently used. When they occur they are long small parallelograms, rarely ornamented, but splayed inside. Many of the apartments were without windows at all.

83. We have, in a previous page, alluded to the Pyramids; to which we here add, that, whatever might have been their purpose, it is certain that the form adopted in them — one

that, among other people, was devoted to the purposes of sepulture—was of all architectural forms that calculated to ensure durability, and was, moreover, well suited to the views of a nation which took extraordinary means to preserve the body after life, and expended large sums on their tombs.

84. ORNAMENT OF DECORATION may be considered under two heads, — that which consists in objects foreign to the forms of the edifices themselves, such as statues, obelisks, &c.; and that which is actually affixed to them, such as the carving on the friezes, bas-reliefs, &c.

85. The former of these are remarkable for the size and beauty of the materials whereof they are composed. First for notice are their statues of colossal dimensions, which are mostly, if not always, in a sitting attitude. The two here given (*fig. 64.*) are from the Memnonium.

They are generally isolated, and placed on simple pedestals. The use of Caryatides, as they are called, perhaps improperly, in Egyptian architecture, if we may judge from remains, does not appear to have been very frequent. In the tomb of Osymandyas, we find, according to Diodorus, that there was a peristylum, 400 feet square, supported by animals 16 cubits high, each in one stone, instead of columns. The same author (vol. i. f. 56. ed. Wesseling), speaking of Psammeticus, says, "Having now obtained the whole kingdom, he built a propylæum, on the east side of the temple, to the God at Memphis; which temple he encircled with a wall; and in this propylæum, instead of columns, substituted colossal statues 12 cubits in height." Statues of sphinxes in allies or avenues were used for ornamenting the dromos of their temples. Of this species of ornament the ruins of Thebes present a magnificent example. They were placed on plinths facing one another, and about ten feet apart. Examples of lions also occur. The form of the Egyptian obelisks is too well known to need a description here. They have been alleged to be monuments consecrated to the sun. From the situation they often occupy, it is clear they were used neither as gnomons nor solar quadrants.

Fig. 64. COLOSSAL STATUES FROM THE MEMNONIUM.

86. Amongst the ornaments affixed to their buildings, or rather forming a part of them, the most frequent are hieroglyphics and bas-reliefs. The custom of cutting the former upon almost every building was, as we now find, for the purpose of record; but it is nevertheless to be considered as ornamental in effect. The figures that are sculptured on the walls of the temples are mostly in low relief, and are destitute of proportion; and, when in groups, are devoid of sentiment. Painting was another mode of decoration. The grottoes of the Thebaid, and other subterranean apartments, abound with pictures, not only of hieroglyphics, but of other subjects. But the taste of all these, either in drawing, colouring, or composition, is not better than that of their sculpture. (See an example in *fig. 65.*) Yet in both these arts, from the precision with which they are cut and the uniformity of line and proportion they exhibit, a certain effect is produced which is not altogether displeasing.

Fig. 65. PRESENTATION TO OSIRIS.

87. The nymphæa lotus, or water lily, seems to have been the type of much of the ornament used for the purpose of decoration. The leaf of the palm tree was another object of imitation, and is constantly found in the capitals of their columns. The use of the palm leaf in this situation may have been derived from a popular notion mentioned by Plutarch, (*Symposiac.* lib. vi. cap. 4.), that the palm tree rose under any weight that was placed upon it, and even in proportion to the degree of depression it experienced. This supposed peculiarity is also mentioned by Aulus Gellius (lib. iii. cap. 6.). The reed of the Nile, with its head, enters into some combinations of ornament; the former, indeed, collected in bundles, seems to have been the type of some of the species of their columns. In their entablatures and elsewhere, animals of all sorts occasionally find a place as ornaments, even down to fishes, which occur in a frieze at Assouan; and, as we have before observed, there are few buildings of importance in which the winged globe does not appear as an ornament.

88. Some observations on the taste, style, and character of Egyptian architecture, will conclude this section. If the type was, as we imagine, derived from the early subterranean edifices of the people, whose customs allowed of no change or improvement, we cannot be surprised at the great monotony that exists in all their monuments. The absence of variety in their profiles, by means of projecting and re-entering parts, of the use of the arch, of the inclined roof, and of all deviation from those shades of different developments, which impart character to a work of art, generated the monotony, the subject of our complaint. It cannot be denied that in those arts which have nature for their model, the artists of Egypt never sought excellence in true representation. Now architecture is so allied to the other arts, that the principles by which they were guided in these latter were carried through in

the former. It was impossible that the abstract imitation of nature, which constitutes almost the essence of architecture, which is founded upon the most refined observations of the impressions of different objects on our senses, which indicates numberless experiments and successive trials, and which therefore requires the independence of the artist, could be developed in a country where the restrictions of religion and the spirit of routine became the dominant genius of all the arts. In positive imitation, whose existence and principles have been already traced from grottoes and hollowed subterranean apartments, the types of Egyptian architecture were unsusceptible of variety, and very remote from that which characterises invention. The monotony thence resulting was attended by another effect, — that of endeavouring to correct it by a profusion of hieroglyphics. As to the other ornaments employed, they seem to have flowed from caprice, both in selection and employment, resting on no fixed principles of necessity or fitness, nor subject to any laws but those of chance. The original forms, indeed, of Egyptian architecture, unfounded, like those of Greece, on a construction with timber, would not suggest the use of ornament. Nothing seemed fixed, nothing determined by natural types. We must, however, except some of their columns, which do appear to have been formed with some regard to imitation.

89. In the architecture of Egypt we find great want of proportion, or that suitable ratio which the different parts of a body should bear to each other and to the whole. In all organised beings, their parts so correspond, that, if the size of a single part be known, the whole is known. Nature has thus formed them for the sake of dependence on and aid to each other. In works of art, the nearer we approach a similar formation, the more refined and elegant will be its productions. Solidity is abused in the works of the Egyptians; the means employed always seem greater than were necessary. This discovers another cause of their monotony. The masses of material which the country produced measured their efforts and conceptions, and their invention was exhausted by a very restricted number of combinations. Their monuments are doubtless admirable for their grandeur and solidity; but the preponderance of the latter, when carried beyond certain bounds, becomes clumsiness; art then disappears, and character becomes caricature. Though we think it useful thus to analyse Egyptian art, it must not be supposed that we are insensible to its imposing, and often picturesque, effect. It can never be revived, and our observations upon it must be understood as in comparison with Greek art, which has proved so susceptible of modification that it is not likely to be abandoned in any part of the world where civilisation has appeared.

90. Though the private dwellings of the Egyptians were not comparable with their public edifices, they were not altogether devoid of splendour. Examples of them from sculptures may be seen in Mr. Wilkinson's work above quoted. In the towns they of course varied in size and plan. The streets were narrow and laid out with regularity; and the mixture, as frequently met with in eastern towns, of large houses with low hovels, appears to have been avoided. In Thebes, the number of stories were, according to Diodorus, in some cases as much as four and five. Houses of small size were usually connected together, rarely exceeding two stories. They were regular in plan, the rooms usually occupying three sides of a court-yard, separated by a wall from the street; or on each side of a long passage from a similar entrance court. The court was sometimes common to several houses. Large mansions were detached, having often *different entrances on their several sides*, with portals very similar in form to those of their temples. These portals were about 12 or 15 ft. high, and on each side was a smaller door. Entering through the porch, the passage was into an open court wherein was a receiving room for visitors, and this was supported by columns, and closed in the lower part by intercolumnal panels. On the opposite side of the court was another door, by which the receiving room was entered from the interior. Three doors led from this court to another of larger dimensions, ornamented with trees, communicating on the right and left with the interior parts of the building, and having a back entrance. The arrangement of the interior was the same on each side of the court; six or more chambers, whose doors faced each other, opened on a corridor supported by columns on the right and left of the area, which was shaded by a double row of trees. A sitting room was placed at the upper end of one of these areas, opposite the door leading to the great court; and over this and the chambers were the apartments of the upper story. On each side of the sitting-room was a door opening on to the street. Of course there were houses on other plans, which are given by Wilkinson; but the above conveys a sufficient idea of their general distribution. On the tops of the houses were terraces, serving as well for repose as exercise. The walls and ceilings were richly painted, and the latter were formed into compartments with appropriate borders. Some of their villas were on a very large scale, and were laid out with spacious gardens, watered by canals communicating with the Nile.

91. We close this section with a list of the principal ancient edifices of Egypt (for which we are indebted to the work of Mr. Wilkinson), whose situations are marked on the accompanying map (*fig. 66.*). At Heliopolis (*modern name Matarieh*) (No. 1.), a little to the north of Cairo, the obelisk of Osirtasen I., and the remains of walls and houses. Near

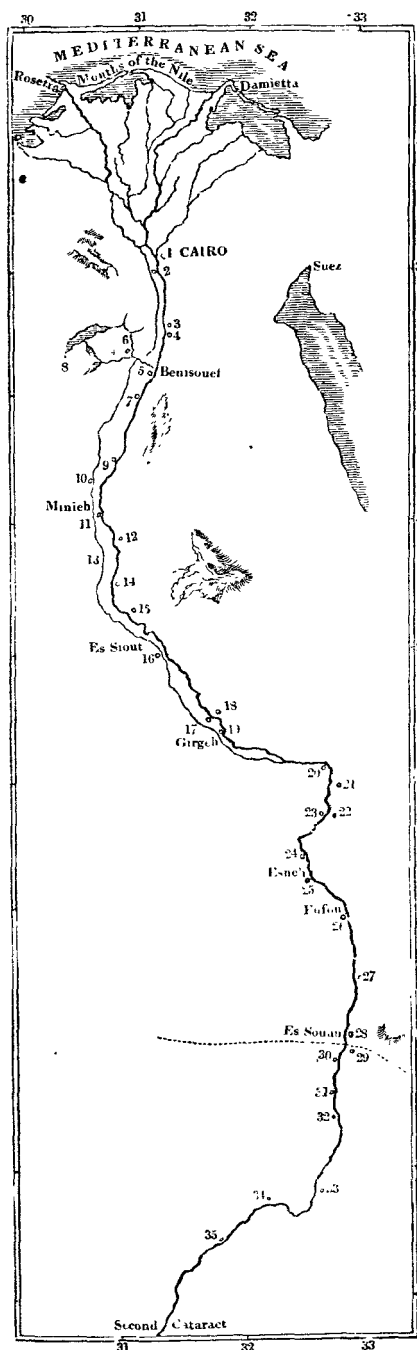

Fig. 66

MAP OF THE NILE.

Cairo, to the south-west, pyramids of Geezeh (No. 2.), Saccara, and Dashoor. At Mitrahani (No. 3.), a colossus of Remeses II.; the mounds of Memphis, fragments of statues, and remains of buildings. About thirty-eight miles above Cairo, on the east bank (No. 4.), are the mounds of Aphroditopolis; and on the opposite bank a false pyramid. Three miles further, on the east bank, the walls of an ancient village called El Heebec (No. 5.), with some hieroglyphics. At Benisooef a road leads to the Fyoom; a brick pyramid at Illahoun (No. 6.), another at El Hawara, and traces of the Labyrinth. An obelisk at Biggig (No. 7.); ruins near Lake Mocris and at Kasr Keroun (No. 8.). From Abou Girgeh (No. 9.), on the west bank, a road to Oxyrinchery (Bahasa) (No. 10.), where are mounds but no ruins. At Gabel e' Tayr, a rock temple. Eight miles below Minieh (No. 11.) is Acoris (Tehneh), on the east bank, where is a Greek Ptolemaic inscription on the cliff, tombs in the rock with inscriptions on the doors, hieroglyphic tablets, &c. On the east bank, seven miles above Minieh, Kom Ahmar, where are the ruins of an old town and some grottoes. Nine miles further up are the grottoes of Beni Hassan (No. 12.); and about a mile and a half further on a grotto or rock temple of Bubastis or Diana. Antinoe (Shekh Abadeh), west bank, few traces of the town, a theatre, principal streets, baths, &c. Outside the town, the hippodrome. At El Bersheh, a grotto, wherein is a colossus on a sledge. Hermopolis, on the west bank (Oshmounayn) (No. 13.), no remains of it. At Gebel Toona are mummy pits, a tablet of hieroglyphics, and statues in high relief. At Shekh Said (No. 14.) the mountains recede to the eastward, leaving the river; a little beyond is the village of Tel eb Amarna, to the north of which are the remains of a small town, and to the south the ruins of a city, which Mr. W. supposes to have been the Alabastron. To the east are grottoes with sculptures; and on the summit of the mountain an ancient alabaster quarry. At El Hargib (No. 15.), the ruins of an old town. At E' Siout (No. 16.) (the ancient Lycopolis) are grottoes. At Gow (Antaeopolis), a few stones of the temple close to the river. At Shekh Heredee, small grottoes; and a Roman statue at the base of the mountain cut out of a piece of the rock. West of Soohag (No. 17.) is the old town of Athribis, where is a Greek inscription in the ruined temple, and grottoes in the mountain. On the east side of the river, opposite, is E'Khimm (No. 18.) (Parcopolis, Greek

inscription of Temple of Pan, and remains of other stone buildings. Mensheeh (No. 19.)

Fig. 67. TEMPLE AT TENTYRIS.

town and of a temple; and at the village of El Qala, to the north, a small Roman Egyptian temple. Qoos (No. 21.) (Apollinopolis parva) no ruins. At Thebes (No. 22.) (Diospolis magna), on the east bank, Karnac and Lugsor; on the west, tombs of the kings, private tombs, several temples, colossi of the plain, &c. At Erment (No. 23.) (Hermonthis), west bank, a temple and early Christian church. At Tofnees and Asfoon (No. 24.) mounds of ancient towns, but no ruins. Esneh (fig. 69.) (Latopolis) (No. 25.) possesses a fine portico, zodiac and quay; sixteen miles from whence is a small stone pyramid. On the east bank, four miles beyond, is El Kab (Eilethyas), where are ruins of a very ancient town; the temples lately destroyed; grottoes in the mountain; Edfu (No. 26.) (Apollinopolis magna) has two temples; and eleven miles above it are the remains of an old town. At Komombo (No. 27.) (Ombos) are two temples, and an ancient stone gateway in a crude brick wall on the east side of the inclosure of the temples. At E' Soaan (No. 28.) (Syene), ruins of a small Roman temple, some columns, granite quarries, in one of which is a broken obelisk. Island of Elephanta, opposite the rocks of E' Soaan, is the Nilometer, with Greek inscriptions relating to the rise of the Nile. A granite gateway bearing the name of Alexander, son of Alexander the Great. At Philæ (No. 29.) temples and ruins. On the Island of Biggeh, opposite Philæ to the west, ruined temple, tablets, &c.

Fig. 68. INTERIOR OF TEMPLE AT TENTYRIS.

and a short distance up the valley three small temples.

Fig. 69. PORTICO AT ESNEH.

92. In Nubia, temples at Dabode (No. 30.) (Paremboli) and Kababshee (No. 31.) (Talmis); to the north of the last a small but interesting temple, called Bayt el Wellea, cut in the rock, and of the time of Remeses II. A temple at Dandoor (No. 32.), and one cut in the rock, of the time of Remeses II., with Gerf Hossayn (Tutizis). At Sabooa (No. 33.), a temple of the time of Remeses II., with an avenue of sphinxes, the adytum cut in the rock, the rest built. At Assaia (No. 34.) or Amada, a temple of Thothmes ancient; and nearly opposite, on the east bank, is Dayr, where is a temple cut in the rock of the date of Remeses II. At Ypsambool (No. 35.) (figs. 70. and 71.), two fine temples

Fig. 70. TEMPLE AT YPSAMBOOL.

Fig. 71. TEMPLE AT YPSAMBOOL.

cut in the rock of the time of Remeses II., and the finest out of Thebes. Above the last-named place there are no buildings of importance mentioned by our author.

## SECT. VIII.

## CHINESE ARCHITECTURE.

93. In the first chapter, the reader will remember, we have said that in the tent is to be found the type of this architecture; and one which, M. de Paw justly observes, cannot be mistaken. We are not aware of the utility of a very minute investigation of its style, which in this country is of no further importance than attaches to the silly decoration of gardens with imitations of its productions; but as the object of this work would not be fully attained without some account of it, we propose to consider it, firstly, with respect to its principles, character, and taste; secondly, with respect to its buildings, their parts, and the method of construction adopted in them.

94. (1.) To judge of the arts of a people, we ought to be acquainted with the people themselves, the constitution of their minds, their power, their habits, and the connection of the arts with their wants and pleasures. As one man differs from another, so do these differ among nations. The desire of improving on what has been done before us, no less distinguishes nations than individuals from each other. Whatever may be the cause, this faculty does not seem to be possessed by the Chinese. Unlike their Indian neighbours, amongst whom appears an exuberance of invention, the arts of imitation in China have been bound in the chains of mechanical skill. Their painters are rather naturalists than artists; and an European, engaged on the foreground of a landscape, tells us that the criticism by a native artist on his work was confined to the observation that he had omitted some fibres and sinkings in some of the leaves of the foliage employed in it. The political and moral subjection of the people seems to have doomed them to remain in that confined circle wherein long habit and repugnance to change have enclosed them.

95. In speaking of the principles of Chinese architecture, the word is used in application to those primitive causes which gave birth to it, and which, in every species of architecture, are the elements of its character and the taste it exhibits. The imitation of the tent, as we have before observed, is the true origin of their buildings; and this agrees with our knowledge of the primitive state of the Chinese, who, like all the Tartar tribes, were nomadic. On this is founded the singular construction of their dwellings, which would stand were the walls destroyed; inasmuch as, independent of them, their roofs rest upon timber framing, just as though they had surrounded tents with enclosures of masonry. Indeed, from the accounts of travellers, a Chinese city looks like a large permanent encampment, as well in respect of its roofs as its extent. If, again, we recur to their concave sloped sides, we can arrive at no other conclusion; and though the carpentry of which they are raised has for ages been subjected to these forms, when we consider the natural march of human invention, especially in cases of necessity, we cannot believe that, in a country where the primitive construction was of timber, the coverings of dwellings would at once have been so simple and so light. Their framing seems as though prepared merely for a canvas covering. Again, we have, if more were wanting, another proof, in the posts employed for the support of their roofs. On them we find resting nothing analogous to the architecture for receiving and supporting the upper timbers of the carpentry; on the contrary, the roof projects over and beyond the posts or columns, whose upper extremities are hidden by the eaves; thus superseding the use of a capital. A canvas covering requires but a slender support: hence lightness is a leading feature in the edifices of China. The system of carpentry (if such it can be called) thus induced, will be noticed under the second head; but we must here observe, that lightness is not at all incompatible with essential solidity of construction; and whilst other materials than those which formed tents have been substituted for them, the forms of the original type have been preserved, making this lightness the more singular, inasmuch as the slightest analogy between those of the original and the copy is imperceptible. This change of material prevents in the copy the appearance of solidity, and seems a defect in the style, unless we recur to the type.

96. A characteristic quality of Chinese architecture is gaiety of effect. Their coloured roofs, compared by their poets to the rainbow, — their porticoes, diapered with variegated tints, — the varnish lavished on their buildings, — the keeping of this species of decoration with the light forms of the buildings, — all these unite in producing, to eyes accustomed to contemplate them, a species of pleasure which they would with difficulty relinquish; and it seems reasonable that the architecture of Europe must appear cold and monotonous to men whose pleasure in the arts is more dependent on their senses than on their judgment.

97. Taste in art is a quality of vague signification, except amongst those whose lives are

passed in its practice; neither is this the place to say, upon that subject, more than that, in the application of ornament or decoration to architecture, it must depend on the method of construction. This is not found in that whereof we are writing. With the Chinese, the art of ornamenting a building is an application of capricious finery and patchwork, in which grotesque representations of subjects connected with their mythology often prevail: yet, in this respect, they exhibit a fertility of invention, and produce beautiful abstract combinations quite in character with the general forms. Indeed, the parts of their architecture are in harmony with each other. All is based upon natural principles, and is so adapted to the few and simple wants of a nation whose enormous population alone seems to render it independent of every other people, that no period can be assigned to the future duration of an architecture which, we apprehend, has existed amongst them from the earliest date of their dwelling in cities.

98. (2.) **TIMBER** is the chief material in use among the Chinese; and that of which the country produces the principal is the *nan-mon*, which, according to some, is a species of cedar; others have placed it among the firs. It is a straight thick tree, and improves with age. De Paw says that it furnishes sticks from twelve to thirteen feet high, of useful wood; but Chambers limits it to a smaller size. Respecting its beauty and duration, all travellers agree. Davis (*Description of the Empire of China*) says that the *nan-mo* is a description of cedar, which resists insects and lime, and appears to be exclusively used for imperial dwellings and temples. It was an article of impeachment against the minister of Kien-loong, that he had presumed to use this wood in the construction of his private palace. According to Du Halde, the iron-wood, *the-ly-mow*, is as tall as the oaks of Europe, but is less in its trunk, and differs from it in colour, which is darker, and in weight. The author does not tell us whether it is employed for columns. The *tse-laù*, also called *mo-wáng*, or king of woods, resembles what we call rosewood; but its use is confined chiefly to articles of furniture. The *tchou-tse*, or bamboo, grows to a great height in China. Though hollow, it is very hard, and capable of bearing great weight. It is employed for scaffolding and sheds of all kinds; and the frame-work of their matted houses for theatrical exhibitions is carried up with bamboos in a few hours. It is in universal use. The missionaries inform us that **BRICK** has been in use with the nation from the earliest period, and of both species, — burnt and merely dried in the sun. Chambers describes the walls of the houses built of this material as generally eighteen inches thick. He says, the workmen bring up the foundations for three or four courses in solid work; after which, as the walls rise, the bricks are used in the alternate courses as *headers* and *stretchers* on the two faces of them; so that the headers meet, and thus occupy the whole thickness, leaving a void space between the stretchers: they then carry up another course of stretchers, *breaking* the vertical joints. **STONE** and **MARBLE** are little employed; not on account of their scarcity, for they are abundant, nor on the score of economy, for they are acquainted with the method of working them, as is proved from their use in public buildings and tombs. Neither can it arise from the difficulty or want of acquaintance with the means of transport; for we find in their gardens immense blocks introduced for the purposes of ornament; and in their marble staircases, the steps, whatever the length, are always in a single piece. The fear of earthquakes, moreover, does not appear to have been a motive for their rejection. That is rather to be found in the climate, which, especially in the southern parts, would, from the great heat and moisture, tend to render their houses unwholesome. In the scaffolding they use for the erection of their buildings, security and simplicity are the principal features; not, however, unmixed with skill. It consists of long poles, so inclined as to make the ascent easy, and is executed without any transverse bearing pieces.

99. The police of architecture among the Chinese is, to an European, a singular feature in its practice; and we cannot refrain from presenting to the reader the curious restrictions imposed upon every class in their several dwellings. Police, indeed, may be said to govern the arts of China. Its laws detail the magnitude and arrangement permitted for the *lon*, or palace of a prince of the first, second, or third degree; for a noble of the imperial family, for a grandee of the empire, for the president of a tribunal, for a mandarin, — for, indeed, all classes. They extend, also, to the regulation of the public buildings of capitals, and other cities, according to their rank in the empire. The richest citizen, unless bearing some office in the state, is compelled to restrict the extent of his house to his exact grade in the country; and whatever form and comfort he may choose to give to the interior, the exterior of his dwelling towards the street must be in every respect consistent with these laws. According to the primitive laws on this subject, the number of courts, the height of the level of the ground floor, the length of the buildings, and the height of the roofs, were in a progressive ratio from the mere bourgeois to the emperor; and the limits of each were exactly defined. The ordinary buildings are only a single story high: the climate seems to discountenance many stories. Though Peking is in the fortieth degree of north latitude, the police obliges the shopkeepers and manufacturers to sleep in the open air under their penthouses in the hottest part of the summer.

100. The *leon* is a building of several stories. Of this sort are almost all the small palaces

built by the emperors in their pleasure gardens. The taste for this class of building at one period prevailed to such an extent that houses were constructed from 150 ft. to 200 ft. in height, flanked by towers extending to 300 ft. Though the emperors have, generally, abandoned these enormous buildings, they are still occasionally erected. Most houses of the country are so slightly built as to be incapable of bearing more than one story. Indeed, the necessity for making the most of an area by doubling and tripling its capacity, which exists in the capitals of Europe, does not operate in China.

101. The houses of the Chinese are uniform in their appearance. We here annex the plan and elevation of one (*figs. 72. and 73.*); from which it will be seen that a large portion of the area is occupied by courts, passages, and gardens. Sir W. Chambers describes those of the merchants at Canton as being, generally, a long rectangle on the plan, two stories high, and the apartments divided on the ground floor by a wide passage, which extends through the whole length. On the side towards the street the shops are placed, beyond which a quadrangular open vestibule leads to the private apartments, which are distributed on the right and left of the passage. There is a salon, usually about 18 ft. or 20 ft. long, and 20 ft. wide, open towards the vestibule, or with a screen of canework to protect it from the sun and rain. At the back are doors extending from the floor about half way to the ceiling; the superior part being of trellis work, covered with painted gauze, which gives light to the bedroom. The partition walls are not carried higher than the ground story, and are lined with mats to the height of three feet, above which a painted paper is used. The pavement is of differently coloured stone, or marble squares. The doors are generally rectangular, of wood, and varnished or painted with figures. Sometimes the communication between apartments is in the form of an entire circle, which some have compared to the aperture of a bird-cage. The windows are rectangular, and filled in with framework in patterns of squares, parallelograms, polygons, and circles, variously inscribed in or intersecting each other. The railwork to the galleries is similarly ornamented. The compartments of the windows are generally filled in with a transparent oyster shell instead of glass. The upper floor, which occupies the whole breadth of the

Fig. 72. GROUND PLAN.

house, is divided into several large apartments, which are, occasionally, by means of temporary partitions, converted into rooms for visitors, apart from the family. The sleeping rooms for the people connected with the business are over the shops. The roof stands on wooden columns; and its extremities, projecting beyond the walls, are usually decorated with the representation of a dragon.

Fig. 73. ELEVATION OF A CHINESE HOUSE.

102. In the system of carpentry practised by the Chinese, the columns and beams look more like the bars of a light cage than the supports and ties of a solid piece of framing, or like a collection of bamboos fastened to one another. The accompanying diagram (*fig. 74.*) will convey our meaning to the reader. Their columns vary in their forms and in their proportions from eight to twelve diameters in height, and are without capitals. They are generally of wood, standing on marble or stone bases, and are occasionally polygonal as well as circular. Some are placed on moulded bases.

Fig. 74. COLUMN AND BRASS-PIECE.

103. The palaces are constructed on nearly the same plan. Nothing, say the missionaries of Peking, gives a more impressive idea of a palace and the greatness of its inhabitant, whether we consider its extent, symmetry, elevation, and uniformity, or whether we regard it for the splendour and magnificence of its parts, than the palace of the emperor at Peking. The whole, they say, produced an effect upon them for which they were not prepared. It occupies an area of upwards of 3600 ft. from east to west, and above 3000 ft. from north to south, without including the three fore-courts. Mr. Barrow, in his *Account of Lord Macartney's Embassy*, describes it as a vast enclosure of a rectangular form, surrounded by double walls, having between them ranges of offices, covered by roofs sloping towards the interior. The included area is occupied by buildings not more than two stories high, and forming several quadrangular courts of various sizes, in the centres of which are buildings standing on granite platforms, 5 ft. or 6 ft. high. These are surrounded by columns of wood, which support a projecting roof turned up at the angles. One of these buildings, serving as a hall of audience, stands like the rest on a platform, and

its projecting roof is supported by a double row of wooden columns, the intervals between which, in each row, are filled with brickwork to the height of 4 ft.; the part above the wall being filled in with lattice work, covered with transparent paper. The courts are intersected by canals spanned by several marble bridges. The gateways of the quadrangles are adorned with marble columns on pedestals, decorated with dragons. The courts contain sculptured lions 7 ft. or 8 ft. high; and at the angles of the building, surrounding each area, are square towers, two stories high, crowned with galleries. The reader will find a delineation of this extraordinary building in Cousin's work, *Du Genie de L'Architecture*, 4to, Paris, 1822, pl. 26. The peristylia of the interior buildings of the palace are built upon a platform of white marble, above which they are raised but a few steps; but this platform is reached by three flights of marble steps, decorated with vases and other ornaments.

104. It is said that there are 10,000 *miao*, or idol temples in Pekin and its environs. Some of these are of considerable size, others are more distinguished for their beauty; there is, however, no sufficient account of them, and we shall therefore proceed to those of Canton, which have been described by Chambers. He says that in this city there are a great number of temples, to which Europeans usually apply the name of *pagoda*. Some of these are small, and consist of a single chamber; others stand in a court surrounded by corridors, at the extremity of which the *ting*, or idols, are placed. The most extensive of these pagodas is at *Ho-nang*, in the southern suburb of Conan. Its interior area is of the length of 590 ft., its width 250 ft. This area is surrounded by cells for 200 bonzes, having no light but what is obtained from the doors. The entrance to the quadrangle is by a vestibule in the middle of one of the short sides; and at the angles are buildings 30 ft. square, in which the principal bonzes reside. In the middle of each of the long sides is a rectangular area, surrounded by cells, one containing the kitchens and refectories, and the other, hospitals for animals, and a burying ground. The great quadrangle contains three pagodas or pavilions, each 33 ft. square on the plan. They consist each of two stories, the lowest whereof is surrounded by a peristyle of twenty-four columns. The basement to each is 6 ft. high, to which there is a flight of steps on each side, and the three basements are connected by a broad wall for the purpose of communication between them, with steps descending into the court. The roofs of the peristylia are concave on the exterior; and the angles, which are curved upwards, are decorated with animals. The sides of the upper story are formed with wooden posts, filled in with open framework. Round the foot on the exterior is a balcony with a rail in front. The roof resembles that of the peristyle, and has its angles similarly ornamented. The buildings are all covered with green varnished tiles.

105. The Chinese towers, which also Europeans call pagodas, are very common in the country. The most celebrated, whereof a diagram is presented here (*fig. 75.*), is thus described by P. Le Comte. Its

Fig. 75.

CHINESE TOWER, OR PAGODA.

form on the plan is octagonal, and 40 ft. in diameter; so that each side is 15 ft. It is surrounded by a wall at a distance of 15 ft., bearing, at a moderate height, a roof covered with varnished tiles, which seems to rise out of the body of the tower, forming a gallery below. The tower consists of nine stories, each ornamented with a cornice of 3 ft. at the level of the windows, and each with a roof similar to that of the gallery, except that they do not project so much, not being supported by a second wall. They grow smaller as the stories rise. The wall of the ground story is 12 ft. thick, and  $8\frac{1}{2}$  ft. high, and is cased with porcelain, whose lustre the rain and dust have much injured in the course of three centuries. The staircase within is small and inconvenient, the risers being extremely high. Each floor is formed by transverse beams, covered with planks forming a chamber, whose ceiling is decorated with painting. The walls are hollowed for numberless niches, containing idols in bas-relief. The whole work is gilt, and seems of marble or wrought stone; but the author thinks it of brick, which the Chinese are extremely skilful in moulding with ornaments thereon. The first story is the highest, but the rest are equal in height. "I counted," says M. Le Comte, "190 steps, of ten full inches each, which make 158 ft. If to this we add the height of the basement, and that of the ninth story, wherein there are no steps, and the covering, we shall find that the whole exceeds a height of 200 ft. The roof is not the least of the beauties which this tower boasts. It consists of a thick mast, whose foot stands on the eighth floor, and rises thirty feet from

the outside of the building. It appears enveloped in a large spiral band of iron, clear by several feet from the pole, on whose apex is a gilt globe of extraordinary dimensions.

106. The word tower has been vaguely applied to all these buildings; but in China there are differences in their application, which are classed under three heads: — 1. *Tui*, or platforms for astronomical or meteorological observations, or for enjoying the air and landscape. 2. *Hou*, such as that just described in detail, being edifices of several stories, isolated and circular, square and polygonal on the plan, built of different materials in different places. 3. *Tu*, which are sepulchral towers. These are commonly massive, of strange but simple forms.

107. The *Pay-leon*, or triumphal arches of the Chinese, are to be found in every city. They are erected to celebrate particular events. Those at *Ning-po* are with a central and two smaller side openings, and are ornamented with polygonal stone columns, supporting an entablature of three or four fasciæ. These are usually without mouldings, the last but one excepted, which is a species of frieze filled with inscriptions. They are crowned with roofs of the usual form, having broad projections, whose angles are turned upwards. The apertures are sometimes square, and sometimes circular headed.

108. China abounds in bridges; but Du Halde and the missionaries have made more of them in their accounts than they appear to deserve. What they have described as a bridge of ninety-one arches between Soo-chow and Hång-chow, was passed by Lord Macartney, and found to be nothing more than a long causeway. Its highest arch, however, was supposed to be between 20 ft. and 30 ft. high, and its length about half a mile. Some of their bridges, however, as in the case of that observed by the late Sir George Staunton (vol. ii. p. 177.), are skilfully constructed. They have long been acquainted with the use of the arch composed of wedge-shaped voussoirs, perhaps long before it was known in Europe. Their great wall is one of their most remarkable monuments. It consists of an earthen mound, retained on each side by walls of brick and masonry, with a terraced platform of square bricks. Its total height is 20 ft., including a parapet of 5 ft. The thickness at the

base is 25 ft., and it diminishes to 15 ft. at the platform. The towers on it, at intervals of about 200 paces, are 40 ft. square at the base, diminishing to 30 ft. at the top; and their height is about 37 ft. Some of the towers, however, are 48 ft. high, and consist of two stories. It extends from the province of Shen-Si to the Wanghay, and in a length of 1500 miles is conducted over mountains, valleys,

FIG. 76.

GREAT WALL OF CHINA.

and rivers, often in places inaccessible to an enemy. (See fig. 76.)

## SECT. IX.

### MEXICAN ARCHITECTURE.

109. The architecture of the people who had possession of America before its discovery by Columbus has a considerable claim upon our attention. When a people appears to have had no means of modelling their ideas through study of the existing monuments of older nations, nor of preserving any traces of the style of building practised by the race from which they originated, their works may be expected to possess some novelty in the mode of combination or in the nature of the objects combined; and, in this point of view, American architecture is not without interest. It is, moreover, instructive in pointing out the bent of the human mind when unbiassed by example in the art.

110. North America was found by the Spaniards advanced in agriculture and civilisation, and more especially so in the valleys of Mexico and Oaxaca. These provinces seem to have been traversed by different migratory tribes, who left behind them traces of cultivation. It is not our intention here to discuss the mode of the original peopling of America; but we must, in passing, observe that the vicinity of the continents of Asia and America is such as to induce us to remind the reader that one of the swarms, which we mentioned in the section on Druidical and Celtic Architecture, might have moved in a direction which ultimately brought them to that which, in modern times, has received the name of the New World. The Toultecs appeared in 648, making roads, building cities, and constructing great pyramids, which are yet admired. They knew the use of hieroglyphical paintings,

founded metals, and were able to cut the hardest stone. (*Humboldt, New Spain.*) The Aztecs appeared in 1196, and seem to have had a similar origin and language. Their works, though they attest the infancy of art, bear a striking resemblance to several monuments of the most civilised people. The rigid adherence of the people to the forms, opinions, and customs which habit had rendered familiar to them, is common to all nations under a religious and military despotism.

111. The edifices erected by the Mexicans for religious purposes were solid masses of earth of a pyramidal shape, partly faced with stone. They were called *Teocallis* (Houses of God). That of ancient Mexico, 318 ft. at the base and 121 ft. in height, consisted of five stories; and, when seen at a distance, so truncated was the pyramid that the monument appeared an enormous cube, with small altars covered by wooden cupolas on the top. The place where these cupolas terminated was elevated 177 ft. above the base of the

Fig. 77.

PYRAMIDS OF TEOTIHUACAN.

edifice or the pavement of the enclosure. Hence we may observe that the *Teocalli* was very similar in form to the ancient monument of Babylon, called the Mausoleum of Belus. The pyramids of Teotihuacan (*fig. 77.*), which still remain in the Mexican Valley, have their faces within 52 minutes of a degree of the cardinal points of the compass. Their interior is clay, mixed with small porous amygdaloid. Traces are

perceived of a bed of lime, which externally covers the stone.

112. The great pyramid of Cholula (*fig. 78.*), the largest and most sacred temple in

Fig. 78.

GREAT PYRAMID OF CHOLULA.

Mexico, appears, at a distance, like a natural conical hill, wooded, and crowned with a small church; on approaching it, its pyramidal form becomes distinct, as well as the four stories whereof it consists, though they are covered with vegetation. Humboldt compares it to a square whose base is four times that of the Place Vendôme at Paris covered with bricks to a height twice that of the Louvre. The height of it is 177 ft., and the length of a side of the base 1423 ft.. There is a flight of 120 steps to the platform. Subjoined is a comparative statement of the Egyptian and Mexican pyramids: —

Dimensions.	EGYPTIAN.				MEXICAN.	
	Cheops.	Cephrenes.	Mycerinus.	Saccara (of five stories).	Teotihuacan.	Cholula.
Height in feet - -	448	398	162	150	171	172
Length of base in feet	728	655	280	210	645	1355

The Cholula pyramid is constructed with unburnt bricks and clay, in alternate layers. As in other *Teocallis*, there are cavities of considerable size, intended for sepulchres. In cutting through one side of it to form the present road from Puebla to Mexico, a square chamber was discovered, built of stones, and supported by beams of cypress wood. Two skeletons were found in it and a number of curiously painted and varnished vases. Humboldt, on an examination of the ruins, observed an arrangement of the bricks for the purpose of diminishing the pressure on the roof, by the *sailing over* of the bricks horizontally. The area on the top contains 3500 square yards, and was occupied by the Temple of Quetzalcoatl, the God of Air, who has yielded his place to the Virgin. By the way, we may here mention that tumuli are found in Virginia, Canada, and Peru, in which there are galleries built of stone communicating with each other by shafts; but these are not surmounted by temples.

113. In the northern part of the intendency of Vera Cruz, west from the mouth of the Rio Tecolutla, two leagues distant from the great Indian village of Papanla, we meet with a pyramidal edifice of great antiquity. The pyramid of Papanla remained unknown to the first conquerors. It is seated in the middle of a thick forest, and was only discovered by some hunters about thirty-five years ago. It is constructed of immense blocks of stone laid in mortar; but is not so remarkable for its size as for its form and the perfection of its finish, being only 80 ft. square at the base, and not quite 60 ft. high. A flight of fifty-seven

steps leads to the truncated pyramid. Like all the Mexican *teocallis*, it is composed of stages, six whereof are still distinguishable, and a seventh appears to be concealed by the vegetation with which its sides are covered. The facing of the stories is ornamented with hieroglyphics, in which serpents and crocodiles, carved in relievo, are discernible. Each story contains a great number of square niches symmetrically distributed. In the first story twenty-four are on each side; in the second, twenty; and in the third, sixteen. The number of these niches in the body of the pyramid is 366, and there are twelve in the stairs towards the east.

114. The military intrenchment of Xochiculco, near Tetlama, two leagues south-west of Cuernavaca, is another remarkable ancient monument. It is an insulated hill, 370 ft. high, surrounded with ditches or trenches, and divided by the hand of man into five terraces covered with masonry. The whole has the appearance of a truncated pyramid, whereof the four faces are in the cardinal points of the compass. The masonry is of porphyry, very regularly cut, and adorned with hieroglyphics; among which are to be seen a crocodile spouting up water, and men sitting cross-legged after the Asiatic fashion. On the platform, which is very large, is a small square edifice, which was most probably a temple.

115. Though the province of Oaxaca contains no monuments of ancient Aztec architecture, which astonish by their colossal dimensions, like the houses of the gods of Cholula, Papautla, and Teotihuacan, it possesses the ruins of edifices remarkable for their symmetry and the elegance of their ornaments. The antiquity of them is unknown. In the district of Oaxaca, south of Mexico, stands the palace of *Mitla*, contracted from *Mignitlan*, signifying, in Aztec, the *place of woe*. By the Tzapotec Indians the ruins are called *leoba*, or *luira* (burial, or tomb), alluding to the excavations found beneath the walls. It is conjectured to have been a palace constructed over the tombs of the kings, for retirement, on the death of a relation. The tombs of Mitla are three edifices, placed symmetrically in a very romantic situation. That in the best preservation, and, at the same time, the principal one, is nearly 130 ft. long. A staircase, formed in a pit, leads to a subterranean apartment, 88 ft. in length, and 26 ft. in width. This, as well as the exterior part of the edifice, is decorated with fret, and other ornaments of similar character (fig. 79.). But the most singular

feature in these ruins, as compared with other Mexican architecture, was the discovery of six porphyry columns, placed for the support of a ceiling, in the midst of a vast hall. They are almost the only ones which have been found in the new continent, and exhibit strong marks of the infancy of the art, having neither base nor capital. The upper part slightly diminishes. Their total height is 19 ft., in single blocks of porphyry. The ceiling under which they were placed was

Fig. 79. ORNAMENTS AT THE PALACE OF MITLA.

formed by beams of Savine wood, and three of them are still in good preservation. The roof is of very large slabs. The number of separate buildings was originally five, and they were disposed with great regularity. The gate, whereof some vestiges are still discernible, led to a court 150 ft. square, which, from the rubbish and remains of subterranean apartments, it is supposed was surrounded by four oblong edifices. That on the right is tolerably preserved, the remains of two columns being still in existence. The principal building had a terrace, raised between three and four feet above the level of the court, and serving as a base to the walls it surrounds. In the wall is a niche, with pillars, four or five feet above the level of the floor. The stone lintel, over the principal door of the hall, is in a single block, 12 ft. long and 3 ft. deep. The excavation is reached by a very wide staircase, and is in the form of a cross, supported by columns. The two portions of it, which intersect each other at right angles, are each 82 ft. long by 25 ft. wide. The inner court is surrounded by three small apartments, having no communication with the fourth, which is behind the niche. The interiors of the apartments are decorated with paintings of weapons, sacrifices, and trophies. Of windows there are no traces. Humboldt was struck with the resemblance of some of the ornaments to those on the Etruscan vases of Lower Italy. In the neighbourhood of these ruins are the remains of a large pyramid, and other buildings.

116. In the intendency of Sonora, which lies north-west of the city of Mexico, and in the Gulf of California, on the banks of the Rio Gila, are some remarkable ruins, known by the name of the *Casa Grande*. They stand in the middle of the vestiges of an ancient Aztec city. The sides are in the direction of the four cardinal points, and are 445 ft. from north

to south, and 276 ft. from east to west. The materials are unburned brick, symmetrically arranged, but unequal in size. The walls are 4 ft. in thickness. The building was of three stories. The principal edifice was surrounded by a wall with towers in it at intervals. From vestiges which appear, it is supposed the town was supplied with the water of the Rio Gila, by an artificial canal. The plain in the neighbourhood is covered with broken earthen pottery painted in white, red, and blue colours.

117. The capital of Mexico, reconstructed by the Spaniards, is undoubtedly one of the finest cities ever built by Europeans in either hemisphere. Perhaps there scarcely exists a city of the same extent which, for the uniform level of the ground on which it stands, for the regularity and breadth of the streets, and the extent of its great square, can be compared to the capital of New Spain. The architecture is pleasing. Ornament is sparingly applied to it; and the sorts of stone employed, which are a porous amygdaloid called *tetzontli*, and a porphyry of vitreous feld-spath, without any quartz, give to the Mexican buildings an air of solidity, and sometimes even of magnificence. The wooden balconies and galleries which disfigure the European cities in both the Indies are discarded. The balustrades and gates are all of Biscay iron ornamented with bronze; and the houses, instead of roofs, have terraces, like those in Italy and other southern countries. It must, however, be admitted, notwithstanding the progress of the arts there during the last thirty years, that it is less from the grandeur and beauty of the edifices, than from the breadth and straightness of the streets, and their uniform regularity and extent, that Mexico commands the admiration of Europeans.

## SECT. X.

### ARABIAN, MORESCQUE, OR SARACENIC ARCHITECTURE.

118. Before the appearance of Mahomet, in the seventh century, and the consequent establishment of Islamism, the Arabians were by no means celebrated for their skill in architecture. The beautiful country of Happy Yemen, wherein were seated the most ancient and populous of the forty-two cities of Arabia enumerated by Abulfeda, does not appear to have produced what might have been expected from the neighbours of the Egyptians, Syrians, Chaldeans, and Persians. The arts of the surrounding nations seem to have been lost upon them. Though a part of their time and industry was devoted to the management of their cattle, still they were collected into towns, and were employed in the labours of trade and agriculture. The towers of Saana, compared by Abulfeda to Damascus, and the marvellous reservoir of Merab, were constructed by the kings of the Homerites, who, after a sway of two thousand years, became extinguished in 502. The latter, the Meriaba, mentioned by Pliny as having been destroyed by the legions of Augustus, was six miles in circumference, and had not revived in the fourteenth century. "But," says Gibbon, "the profane lustre of these was eclipsed by the prophetic glories of Medina and Mecca." Of the ancient architecture of Arabia there are so few examples remaining, that no satisfactory account can be given of it. Excavations, still seen in rocks, are said to be the houses of the people called Thamud; but the Caaba of Mecca is the only one of the seven temples in which the Arabians worshipped their idols now in existence. It is a quadrangular building, about 36 ft. long, 34 ft. broad, and about 40 ft. high. It is lighted by a door on the east side, and by a window, and the roof is supported by three octangular pillars. Since its adoption by Mahomet, it has been enclosed by the caliphs with a quadrangle, round which are porticoes and apartments for the pilgrims resorting to it. Here were the tombs of the eighty descendants of Mahomet and of his wife; but, in 1803, they were destroyed by the Wahabees, who, however, respected and spared the Caaba and its enclosures.

119. The extraordinary conquests from the Indus to the Nile, under Omar, the second caliph, who, after a reign of ten years, died in A. D. 644, brought the victorious Moslems in contact with nations then much more civilised than themselves. As their empire extended, their love for the arts and sciences increased. The first mosque built out of the limits of Arabia is supposed to be that which was founded by Omar on the site of the ancient temple at Jerusalem. Under the dynasty of the Omniades, of which race Omar was a member, the cultivation of architecture was carried on with success. The seat of the empire was removed to Damascus, which was considerably enlarged and improved. Among its numerous splendid buildings was the celebrated mosque founded by Alwalid II. It was he who introduced the lofty *minaret*, which, though an innovation at the time, seems, in later years, to have been as necessary a portion of the mosque as the main body of it. This caliph made considerable additions to the mosque at Medina, as he also did to that which had been built by Omar on the site of the Temple of Solomon, above mentioned. His generals and governors of provinces seem to have been equally zealous in the cause of art and the prophet; witness the mosque built by one of the former on taking Samarcand, and

the universal improvement in the provinces under the sway of the latter. Great as were the works just mentioned, the removal of the seat of the empire to the western frontier of Persia, by the second caliph of the dynasty of the Abassides, gave a lustre to Arabian architecture which almost surpasses belief. Almansor, the brother and successor of Saffah, laid the foundations of Bagdad in the year 145 from the Héjira (A. D. 762), a city which remained the imperial seat of his posterity during a period of five hundred years. The chosen spot is on the eastern bank of the Tigris, about fifteen miles above Modain; the double wall was of a circular form; "and such," says Gibbon, "was the rapid increase of a capital, now dwindled to a provincial town, that the funeral of a popular saint might be attended by eight hundred thousand men and sixty thousand women of Bagdad and the adjacent villages." The magnificence displayed in the palace of the caliph could only be exceeded by that of the Persian kings; but the pious and charitable foundation of cisterns and caravanseras along a measured road of seven hundred miles, has never been equalled.

120. About A. D. 660-5, the prudence of the victorious general Akbah had led him to the purpose of founding an Arabian colony in the heart of Africa; and of forming a citadel that might secure, against the accidents of war, the wealth and families of the Saracens. With this view, under the modest title of a caravan station, he planted the colony of Cairoan, in the fiftieth year of the Héjira. "When," observes Gibbon, "the wild beasts and serpents were extirpated, when the forest, or rather wilderness, was cleared, the vestiges of a Roman town were discovered in a sandy plain: the vegetable food of Cairoan is brought from afar; and the scarcity of springs constrains the inhabitants to collect, in cisterns and reservoirs, a precarious supply of rain water. These obstacles were subdued by the industry of Akbah; he traced a circumference of three thousand and six hundred paces, which he encompassed with a brick wall; in the space of five years the governor's palace was surrounded with a sufficient number of private habitations; a spacious mosque was supported by five hundred columns of granite, porphyry, and Numidian marble."

121. "In the West, the Omniades of Spain," says the same author, "supported with equal pomp the title of Commander of the Faithful. Three miles from Cordova, in honour of his faithful Sultana, the third and greatest of the Abdalrahmans constructed the city, palace, and gardens of Zehra. Twenty-five years, and above three millions sterling, were employed by the founder: his liberal taste invited the artists of Constantinople, the most skilful sculptors and architects of the age; and the buildings were sustained by twelve hundred columns of Spanish and African, of Greek and Italian marble. The hall of audience was incrustured with gold and pearls, and a great bason in the centre was surrounded with the curious and costly figures of birds and quadrupeds." The streets and houses at this place are hollowed out of the rock, which stands 1200 feet above them.

122. Whether we contemplate the materials furnished by Babylon and its neighbourhood, the dismantled towns of Syria, or the abundant ruins of Egypt, and from Tripoli to the Atlantic, it is curious, as the historian of the western Arabs has remarked, to observe that no people constructed, without recourse to the quarry, so many magnificent edifices. In Spain, this was most remarkably the case, whereof the reader will be convinced by reference to Murphy's *Arabian Antiquities*, and Laborde's *Voyage Pittoresque de l'Espagne*.

123. From the latter half of the eighth century to nearly the middle of the ninth, the progress of the Arabians in the sciences was wonderful. Their merit, however, in the art which it is our province to investigate, was of a class inferior to that of the people who invented and carried into execution, though later, the principles which regulated the stupendous monuments of Gothic architecture in Europe. They certainly understood the science of architecture; and works on it were written for the benefit of those whose occupations led them to take an interest in the art.

124. We regret that our limits do not permit us to dwell on the progress in the sciences made by the Arabians, though some of them are intimately connected with our subject. But the information we omit will be much more satisfactorily obtained by the reader consulting the pages of the historian of the decline and fall of the Roman Empire. Our purpose is now to present a concise view of the architecture of the Arabians from Laborde's *Voyage Pittoresque de l'Espagne* (vol. ii. part 1. xliii. et seq.); observing, by the way, that, from our own study of the subject, we are inclined fully to adopt it. In Spain there is a sufficient number of monuments of architecture to class them chronologically, and to assign an epoch to the different styles they exhibit. Though the species does not resemble that which has been denominated Gothic, which is clearly not an imitation, the one and the other sprung from the same source. The point of departure was the architecture of Byzantium, in which city, after the fall of Italy, a totally new style arose, whose development in different modes was the basis of all modern architecture. As though the Coliseum had furnished the hint, the immense edifices, in the style of the period, were constructed with a multiplicity of stories, — they were heavy without, though lightly and richly decorated within; the artists employed in their erection seeming to aim at a transference to the architecture and sculpture on which they were engaged of the oriental profusion of ornament visible in the stuffs of India. This Byzantine school produced the Lombard and

Saxon styles in the North, on which we shall enlarge in the section on Gothic architecture; and, in the South, it produced the Arabian, Saracenic, or Moresque style, by whichever name the reader may choose to distinguish it. Both were strongly impregnated with the vices and defects into which the Roman architecture of the period had fallen. For the sake of illustrating what we mean, we refer, as examples, to the Baths of Dioclesian, to that emperor's palace at Salona, and to the buildings of Justinian and Theodosius,—from all which may be learned the abuses and incongruities which attended the fall, not only of architecture, but of all the other arts. We find in them arches springing from capitals, columns without entablatures, and even zigzag ornaments. But, with all this perversion of taste, the general form of the plans of the edifices altered not: that of the temples more particularly continued unchanged. Some great convulsion was necessary before they could undergo alteration, and such was the introduction of Christianity. Thus, says Saint Isidore, the basilica suffered transformation into the Christian church: — “*Basilicæ olim negotiis plenæ, nunc votis pro salute susceptis.*” Of this, in a succeeding page, we shall have more to say. But the change was not confined to the basilica; the palace and domestic dwelling equally partook of the alteration of wants. The Romans, whilst masters of the world, were careless in protecting their cities by walls. Defence was only necessary on their frontiers; and there, walls and towers were constructed, from which was the first hint for the castle, of which the Roman villa, *fortified*, is the type. When, however, Italy was invaded, the fate of war soon caused exterior decoration to be sacrificed to internal comfort and luxury; and even Rome, under Belisarius, was surrounded by walls and towers. The people, whose prowess made these precautions necessary, soon found the convenience of adopting similar habits and buildings.

125. The Arabians, whose wandering life could scarcely be imagined capable of such a change, ultimately established themselves in Roman castles, and turned the Christian churches, which, at the period, were extremely numerous, into mosques. For some time, the architecture of the Goths, of the Arabians or Moors, was, as respects plan, the same; not less so was the character of the ornaments employed by both nations; but it was not long before these diverged into styles which possessed each its peculiar beauties. The Christians soon used the pointed arch; and the style they adopted became slender and tall, whilst that of the Moslems, from the nature of the climate and their peculiar habits, was deficient in elevation, though in the end it acquired a lightness and elegance which it did not at its origin possess. But it is proper, here, to impress on the mind of the reader that Gothic and Arabian architecture have nothing in common between them, except their origin from a common source. It is an error to confound them, or to suppose that the pointed arch is found in any strictly Arabian edifices. That, as far as we can ascertain, did not exist before the eleventh century. It seems to have been a development in the parts of a style which, as it passed into more northern latitudes, became more acute in the roofs, from the necessity of discharging the rain and snow with greater facility. This pointed style spread itself over some parts of India; but, there, none of the examples are older than the fourteenth or fifteenth century. Except in ornamental detail, whereof we append two specimens (*figs. 80, 81.*) from the Alhambra, the Arabs were not inventive. It is not

FIG. 80.

PAVEMENT, ALHAMBRA.

unlikely that their skill in geometry greatly assisted them in the extraordinary combination

FIG. 81. CAPITAL, ALHAMBRA.

of lines to be found in their decorations, which nothing can surpass ; nor was it till the time of the Abassides that the Arabians became fully acquainted with what had been done by the Greeks. This knowledge was not confined to them, for there is abundant proof, 1. That all the modern arts, as well of the North, as of the West and South, had their origin from the Greek empire at Constantinople, which at that period gave the fashion in them, as did Italy five centuries afterwards. 2. That the plans of churches and mosques are traceable to that of the ancient basilica, as in the citadels of the middle ages, and the palaces of the Greek emperors, are to be found the types of the Gothic castle and of the Moresque alcazar. 3. That the Gothic and Saracenic styles attained their several perfection in very different manners as to the details of their distribution and ornament, and acquired peculiar characters, which in both may be divided into three periods, the last in each being lost in the change that took place in Italy on the revival of the arts. The periods of the Gothic will be noticed under the proper section.

126. The *first period* in the history of Moresque architecture is from the foundation of Islamism to the ninth century, of which the finest example was the Mosque of Cordova in Spain. This was commenced in 770 by Abderahman, and finished by his son and successor, Hisham. Its plan is a parallelogram, whose longest side is 620 ft. by 440, formed by a wall and counterforts, both of which are embattled. The height of the wall varies from 35 to 60 ft., and its thickness is 8 ft. The whole of the quadrangular space is internally divided into two parts, viz. a court of 210 ft. in depth, the mosque itself covering the remainder of the area. The mosque consists of nineteen naves (of a portion of one whereof *fig. 82.* is a

FIG. 82. MOSQUE AT CORDOVA.

diagram) formed by seventeen ranks of columns, and a wall pierced with arches, from south to north, and thirty-two narrower naves from east to west. Each of these naves is about 16 ft. wide from north to south, and about 400 ft. long, their width in the opposite direction being less. Thus the intersection of the naves with each other produces 850 columns, which, with fifty-two columns in the court, form a total of upwards of 900 columns. They are about 18 in. in diameter, the mean height of them is about 15 ft., and they are covered with a species of Corinthian and Composite capital, of which there are many varieties. The columns have neither socle nor base, and are connected by arches from one to another. The ceilings are of wood, painted, each range forming, on the outside, a small roof, separated from those adjoining by a gutter. The variety of the marbles of the columns produces an effect of richness which all agree is very striking. They were most probably procured from the Roman ruins of the city. It is impossible to pass over the description of this mosque without calling to mind the resemblance it bears in its arrangement to the basilicas at Rome. The reader who has seen St. Agnese and St. Paolo fuori le mura, we are sure, will think with us. After the conquest of Cordova in 1236, this mosque was converted into a cathedral. In 1528, it was much disfigured by modern erections, which were necessary for better adapting it to the service of the Christian religion. These, however, have not so far ruined its ancient effect as to prevent an idea being formed of it when in its splendour. The decorations throughout are in stucco, painted of various colours, decorated with legends, and occasionally gilt like the churches of the Lower Empire.

127. In the *second period*, the style greatly improved in elegance. It lasted till the close of the thirteenth century, just before which time was founded the royal palace and fortress of the Alhambra, at Granada (*fig. 83.*), perhaps the most perfect model of pure Arabian architecture that has existed. During this period, no traces of the Byzantine style are to be found. An exuberance of well-tempered ornament is seen in their edifices, whose distribution and luxury manifest the highest degree of refinement. Speaking of the interior of the building above mentioned, M. de Laborde says, that it exhibits "tout ce que la volupté, la grâce, l'industrie peuvent réunir de plus agréable et de plus parfait." After passing the principal entrance, you arrive at two oblong courts ; one whereof, celebrated in Arabian history, called the Court of the Lions, is in *fig. 84.* represented on the following page. This court is 100 ft. long and 50 ft. broad, having 128 columns of white marble. Round these two courts, on the ground floor, are disposed the apartments of the palace. Those for state look out towards the country ; the rest, cooler and more retired, have openings for light under the interior porticoes. The whole is on one plane, the walls being placed so as exactly to suit the plateau of the rock ; its entire length is about 2300 ft., and breadth 600 ft. The doors are few and large, and the windows, except on the side where the landscape is most magnificent, are chiefly towards the interior. In one of the apartments, the Arabian architect has, in an inscription, given his reason for this adoption, in the following terms : — "My windows admit the light, and exclude the view of external objects, lest the beauties of

nature should divert your attention from the beauties of my work." The walls are covered with arabesques, apparently cast in moulds, and afterwards joined together. The orna-

FIG. 83.

PLAN OF THE ALHAMBRA.

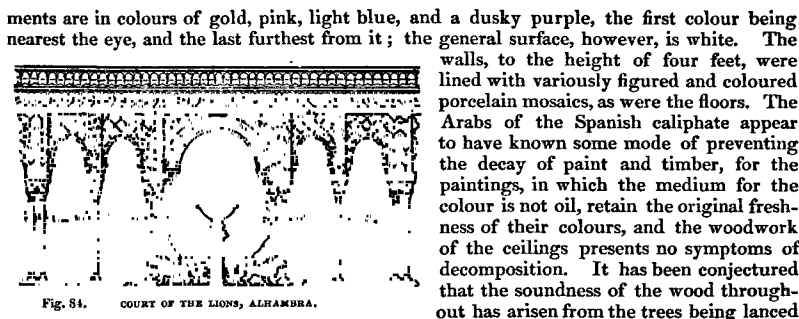

FIG. 84. COURT OF THE LIONS, ALHAMBRA.

ments are in colours of gold, pink, light blue, and a dusky purple, the first colour being nearest the eye, and the last furthest from it; the general surface, however, is white. The walls, to the height of four feet, were lined with variously figured and coloured porcelain mosaics, as were the floors. The Arabs of the Spanish caliphate appear to have known some mode of preventing the decay of paint and timber, for the paintings, in which the medium for the colour is not oil, retain the original freshness of their colours, and the woodwork of the ceilings presents no symptoms of decomposition. It has been conjectured that the soundness of the wood throughout has arisen from the trees being lanced or drained of their sap at the time of felling; but it may be, that the coating of paint has had some effect in producing the result. Description conveys no notion of this extraordinary edifice: the reader who wishes to obtain one must refer to Murphy's work, already mentioned.

128. The *third period* of Arabian architecture is from the end of the thirteenth century to the decline of the Saracen power in Spain. During a portion of this period, it was used by the Spaniards themselves, and like the Gothic, in the northern and middle parts of Europe, was engrafted on the style which crept from Italy into all countries till the Renaissance. During this period were built the castles of Benavento, Penafel, and Tordesillas; and the alcázars of Segovia and Seville. The plans continued much the same; but Greek ornaments began to appear, with Moresque arches on Corinthian columns. At this time, also, representations of the human figure are to be seen, which, by the laws of Mahomet, were strictly forbidden. There was a charm about this architecture which makes one almost regret that reason and advance in civilisation have extinguished it.

129. We are not to look to the works of the Arabians for the real grandeur which is exhibited in the works of Egypt, Greece, or Rome. Brick was the material most used. When stone was employed, it was covered with a coating of stucco. In their constructive combinations there is nothing to surprise. The domes which crown their apartments are neither lofty nor large in diameter, neither do they exhibit extraordinary mechanical skill. The Arabian architects seem to have been unacquainted with the science of raising vaults on lofty piers. In the specimen cited at Cordova, the span, from pier to pier is less than 20 ft., which would not have required much skill to vault, yet we find the ceilings of timber. The use of orders was unknown to them; the antique columns which they introduced were employed as they found them, or imitations of them, without an acquaintance with the types from which they were derived, with their principles or proportions. In truth,

their columns are posts. We do not find, in the forms of Arabian art, that character of originality which can be traced from local causes. The Arabians had spread themselves out in every direction, far from their own country, in which they had never cultivated the arts; hence their architecture was founded upon the models before them, which the

Fig. 85. ARABIAN ARCHES.

Byzantine school supplied. Of the forms of their arches, some whereof are here exhibited (*fig. 85.*), the most favourite seems to have been the horse-shoe form. They may be ranged into two classes, — that just named, and the other, that wherein the curve is of contrary flexure, and described from several centres. Both classes are vicious in respect of construction, from the impossibility of gaining resistance to thrust at the abutments. In masonry, such arches could not be executed on a large scale. In brick arches, however, the surface of the cement is so increased, that if it be good, and great care be used in not removing the centres till the cement is set, great variety of form in them may be hazarded. If the pleasure — perhaps we may say sensuality — of the eye is alone to be consulted, the Arabians have surpassed all other nations in their architecture. The exquisite lines on which their decorations are based, the fancienciness of their forms, to which colour was most tastefully superadded, are highly seductive. Their works have the air of fairy enchantment, and are only to be compared to that imagination with which the oriental poetry abounds. The variety and profusion wherewith they employed ornament impart to the interior masses of their apartments the appearance of a congeries of painting, incrustation, mosaic, gilding, and foliage; and this was probably much augmented by the Mahometan law, which excluded the representation of the human figure. If a reason be unnecessary for the admission of ornament, nothing could be more satisfactory than the splendour and brilliancy that resulted from their combinations. One of their practices, that of introducing light into their apartments by means of openings in the form of stars, has a magical effect.

130. We have principally confined ourselves, in the foregoing remarks, to the architecture

of the Arabians as it is found in Spain, which, it is proper to observe, is only a class of the edifices in the style. There is so close a resemblance between the buildings of that country and those of other places that were, and still are, under the dominion of the Moors, that, allowing only for difference of climate, we might have left the subject without further illustration, but that we think the representation in *figs. 86. and 87.* of a Turkish house at Algiers, which we have extracted from Durand's *Parallèle des Edifices*, may give a better idea of Arabian architecture than a host of words.

Fig. 86. PLAN, HOUSE AT ALGIERS.

Fig. 87. ELEVATION, HOUSE AT ALGIERS.

131. In *Mecca*, the city of the Prophet, the houses are of stone, and three or four stories in height. The material employed indicates solidity of construction. The streets are regular. The

leading features are — the balconies covered with blinds; fronts of the houses much ornamented; doors, with steps and small seats on both sides; roofs terraced, with very high parapets, opened at intervals by a railing formed of brick, in which holes are left for the circulation of the air, at the same time giving an ornamental appearance to the front; staircases narrow and inconvenient; rooms of good dimensions and well-proportioned, having, besides the principal windows, an upper tier. *Damascus*, of which a slight view (*fig. 88.*) is annexed, has been described as resembling a large camp of conical tents, which, on a nearer approach, are found to be small cupolas to the houses. Brick, sun-dried, is the principal material, and the forms of the roofs mentioned are absolutely necessary to protect against the winter rains. Streets generally narrow, houses well supplied with fountains, and containing a large number of houses that may be ranked as palaces. Mosques, many in number, but presenting none that are very remarkable. The bazaars and baths of considerable size and splendour. In *Bagdad*, there are many large squares. The gates erected by the caliphs are still in existence, and are fine specimens of Arabian art. Its walls of mud are 25 ft. in height, but within them are ramparts, carried on arches. In *Bussorah*, the most remarkable feature is the mode in which they construct their arches, which is effected without centres.

132. We do not think it necessary to detain the reader on the architecture of Moorish or Western Arabia. As in the eastern parts of the ancient empire, the houses usually consist of a court, whereof some or all of its sides are surrounded by galleries. Narrow rooms run generally parallel with the gallery, usually without any opening but the door

opening on to the gallery. Roofs are flat or terraced. Walls variously built, often of lime, plaster, and stones, carried up in a sort of casing, which is removed when the work is set.

Fig. 88.

VIEW OF FEZ.

From want of good timber, the rooms are narrow. The mosques are by no means worthy of notice. *Fez*, an ancient Arabian city, contains some lofty and spacious houses. Its streets are narrow, and on their first floors have projections which much interrupt the light. In the centre of each house is an open quadrangle, surrounded by a gallery, communicating with a staircase. Into this gallery the doors of the apartments open. The ceilings are lofty, the floors of brick. All the principal houses are supplied with cisterns in the lower parts, for furnishing a supply to the baths, a luxury with which also every mosque is provided. In this town there are nearly two hundred caravanseras or inns, three stories high, in each of whose apartments, varying from fifty to one hundred, water is laid on for ablution. The shops, as in *Cairo*, are very small; so much so, that the owner can reach all the articles he deals in without changing his posture. In *Tripoli*, the houses rarely exceed one story in height; but we must be content with observing that the character is still the same. "Nec facies omnibus una, nec diversa tamen." Though the late Sultan built a new palace in the Italian style at Constantinople, the Moslems will not easily relinquish a style inti-

Fig. 89.

ENTRANCE TO A RECEPTION ROOM OF THE SERAGLIO.

mately allied to their habits and religion, a style whereof *fig. 89.* will convey some idea to the reader. He is also referred to *figs. 31, 32, and 33.*, as examples of the same style in Persia.

## SECT. XI.

## GRECIAN ARCHITECTURE.

133. The architecture of Greece is identical with columnar architecture. Writers on the subject have so invariably treated the hut as the type on which it is formed, that, though we are not thoroughly satisfied of the theory being correct, it would be difficult to wander from the path they have trodden. In the section on Egyptian architecture, we have alluded to the tombs at Beni-hassan, and we here present a representation of a portion of them from a sketch with which we were favoured many years since by Mr. Charles Barry

Fig. 90.

TOMB AT BENI-HASSAN.

(fig. 90.). The reader will, in it, be struck by the appearance of the Doric column, almost in its purity. Wilkinson (*Manners and Customs of the Ancient Egyptians*) is of opinion that the date of these tombs is 1740 B. C., that is, in the time of the first Osirtasen, an antiquity which can be assigned to no example in Greece. These tombs are excavated in a rock, a short distance from the Nile, on its right bank, about forty-eight French leagues south of Cairo. Two of them have architectural fronts like the above plate. The columns are five diameters and a half in height. The number of the flutes, which are shallow, is 20, and the capital consists of a simple abacus. There are no indications of a base or plinth.

Above the architrave, which is plain, there is a projecting ledge of the rock, somewhat resembling a cornice, whose soffit is sculptured, apparently in imitation of a series of reeds, laid transversely and horizontally. There certainly does, in this, appear some reference to imitation of a hut, and the refinement of the Greeks, in after ages, may have so extended the analogy as in the end to account for all parts of the entablature. The tradition doubtless existed long before Vitruvius wrote, who gives us nothing more than the belief of the architects of his time. The point is not, at this time, likely to be answered satisfactorily; if it could, it might be important, as leading to the solution of some points of detail, which limit the propriety or impropriety of certain forms in particular situations. Having thus cautioned the reader against implicit faith in the system we are about to develop, we shall preface it by the opinion, on this subject, of M. Quatremère de Quincy, an authority of great value in everything that relates to the art. Carpentry, says that writer, is incontestably the model upon which Greek architecture is founded; and of the three models which nature has supplied to the art, this is, beyond doubt, the finest and most perfect of all. And again, he observes, whoever bestows his attention on the subject, will easily perceive that, by the nature of it, it includes all those parts that are effective for utility and beauty, and that the simplest wooden hut has in it the germ of the most magnificent palace.

134. We must here premise that this section is strictly confined to the architecture of Greece and its colonies. Much confusion has arisen from the want of strict limits to the term *Grecian Architecture*, one which has been indiscriminately applied to all buildings in which the orders appear. The orders were altered in their profiles, proportions, and details by the Romans; and though between them and those of the Greeks there is a general resemblance, and their members are generally similar, yet, on a minute examination, great difference will be found. In the former, for instance, the contour of every moulding is a portion of a circle; in the latter, the contours of the mouldings are portions of conic sections. In Roman architecture, we find the dome, which in Greek architecture never occurs. In the latter, the arch is never seen; in the former, it is often an important feature. Indeed, the columnar style, as used by the Greeks, rendered arches unnecessary; hence, in all imitation of that style, its introduction produces a discord which no skill can render agreeable to the educated eye. Attempts have been made by the modern German architects to introduce the use of the arch with Greek forms; but they have been all signal failures, and that because it is incapable of amalgamation with the solemn majesty and purity of Greek composition. Before such blending can be accomplished with success, the nature of pure Greek architecture must be changed.

135. Following, then, the authors, ancient and modern, on the origin of the art, we now proceed to a development of its origin. The first trees or posts which were fixed in the earth for supporting a cover against the elements, were the origin of the isolated columns which afterwards became the supports of porticoes in temples. Diminishing in diameter

as they rose in height, the tree indicated the diminution of the column. No type, however, of base or pedestal is found in trees: hence the ancient Doric is without base. This practice, however, from the premature decay of wood standing immediately on the ground, caused the intervention of a step to receive it, and to protect the lower surface from the damp. Scamozzi imagines that the mouldings at the bases and capitals of columns had their origin in cinctures of iron, to prevent the splitting of the timber from the superincumbent weight. Others, however, are of opinion that the former were used merely to elevate the shafts above the dampness of the earth, and thereby prevent rot. In the capital, it seems natural that its upper surface should be increased as much as possible, in order to procure a greater area for the reception of the architrave. This member, or chief beam, whose name bespeaks its origin, was placed horizontally on the tops of the columns, being destined, in effect, to carry the covering of the entire building. Upon the architrave lay the joists of the ceiling, their height being occupied by the member which is called the frieze. In the Doric order, the ends of these joists were called triglyphs, from their being sculptured with two whole and two half glyphs or channels. These, however, in the other orders in strictly Greek architecture, do not appear in the imitation of the type, though in Roman architecture it is sometimes otherwise, as in the upper order of the Coliseum at Rome, where they are sculptured into consoles. The space between the triglyphs was, at an early period of the art, left open, as we learn from a passage in the *Iphigenia* of Euripides, where Pylades advises Orestes to slip through one of the metopæ, in order to gain admission into the temple. In after times, these intervals were filled up, and in the other orders they altogether disappear, the whole length of the frieze becoming one plain surface. The inclined rafters of the roof projected over the faces of the walls of the building, so as to deliver the rain clear of them. Their ends were the origin of the mutule or modillion, whereof the former had its under side inclined, as, among many other examples, in the Parthenon at Athens. The elevation, or as it is technically termed, pitch of the pediment, followed from the inclined sides of the roof, whose inclination depended on the nature of the climate. Thus authors trace from the hut the origin of the different members of architecture which a consideration of the annexed diagram will make more intelligible to the reader. *Figs. 91. and 92. exhibit the parts of a roof in elevation and section: a a are the architraves or*

*trabes; b b the ridge piece or column; c the king-post or columna of a roof; d d the tie-beam or transtrum; e the strut or capreolus; f f the rafters or cantherii; g g g g the purlines or templa; h h the common rafters or asseres.* The form of the pediment became an object of so much admiration, and so essential a part of the temple, that Cicero says, if a temple were to be built in heaven, where no rain falls, it would be necessary to bestow one upon it. "Capitolii fastigium illud, et cæterarum ædium, non venustas sed necessitas ipsa fabricata est. Nam cum esset habita ratio quemadmodum ex utraque parte tecti aqua delaberetur utilitatem templi fastigii dignitas consecuta est, ut etiam si in cælo capitolium statueretur ubi imber esse non potest, nullam sine fastigio dignitatem habiturum fuisse videatur." (*De Oratore*, lib. iii.) The inclination of the pediment will be hereafter discussed, when we speak on the article Roof, in another part of the work. Under the section on Cyclopean Architecture, mention has been made of the works at Tiryns and Mycene. We do not think there is sufficient chain of evidence to connect those ruins with the later Grecian works, though it must be confessed that the temples of Sicily, especially at Selinus, and perhaps those at Pæstum, are connecting links. Perhaps the sculptures at Selinus might be properly called Cyclopean sculpture, in its more refined state.

136. Architecture, as well as all the other arts, could only be carried to perfection by slow steps. Stone could not have been used in building until the mechanical arts had been well known. It is curious that Pliny gives the Greeks credit only for caves as their original dwellings, from which they advanced to simple huts, built of earth and clay. His words are (lib. vii. s. 57.), "Laterarias ac domos constituerunt primi Euryalus et Hyperbias

fratres Athenis : antea specus erant pro domibus." This, perhaps, is no more than a traditional fable. Fables of this kind, however, often have some foundation in fact. We are not always inclined to discard them, for we have little more than tradition for the early excellence of the Athenians in civilisation, a nation among the Greeks who first became a body politic, and whose vanity caused them to assume the name of *Αυτοχθόνες*, from a belief, almost sanctioned by Plato, that their ancestors actually rose from the earth. How strong the prevailing opinion was of the original superiority of the Athenians, may be gathered from Cicero, in his oration for Flaccus. "Adsunt," he says, "Athenienses, unde humanitas, doctrina, religio, fruges, jura, leges ortæ, atque in omnes terras distributæ putantur : de quorum urbis possessione, propter pulchritudinem, etiam inter deos certamen fuisse proditum est : quæ vetustate eâ est, ut ipsa ex sese suos cives genuisse dicatur." But we shall not attempt, here, an early history of Greece ; for which this is not the place, and, if accomplished, would little answer our views. The Greeks exhibited but little skill in their earliest edifices. The temple of Delphi, mentioned by Homer, in the first book of the *Iliad* (v. 404. et seq.), which Bryant supposes to have been originally founded by Egyptians, was, as we learn from Pausanias (*Phocic*. c. 5.), a mere hut, covered with laurel branches. Even the celebrated Areopagus was but a sorry structure, as we learn from Vitruvius (lib. ii. cap. 1.), who judged of it from its ruins. The fabulous Cadmus — for we cannot help following Jacob Bryant in his conjectures upon this personage — has been supposed to have existed about 1519 a. c., to have instructed the Greeks in the worship of the Egyptian and Phœnician deities, and to have taught them various useful arts ; but this carries us so far back, that we should be retracing our steps into Cyclopean architecture, if we were here to dwell on the period ; and we must leave the reader — as is our own, and as we apprehend will be the case with all who may succeed us — to grope his way out of the darkness as best he may.

137. The earliest writer from whom gleanings can be made to elucidate the architecture of Greece is the father of poets. To Homer we are obliged to recur, little as we approve of the architectural graphic flights in which the poet is wont generally to indulge. Though the *Odyssey* may not be of so high antiquity as the *Iliad*, it is, from internal evidence, of great age, for the poem exhibits a government strictly patriarchal, and it sufficiently proves that the chief buildings of the period were the palaces of princes. We may here, in passing, observe, that in Greece, previous to Homer and Hesiod, the sculptor's art appears to have been unknown, neither was practised the representation of Gods. The words of Athenagoras (*Leg. pro Christ.* xiv.) are — *Αἱ δ' εἰκόνες μέχρι μὴ τῷ πλαστικῇ, καὶ γραφικῇ, καὶ ἀνδριαντοποιητικῇ ἦσαν, οὐδὲ εὐομιζόντο*. The altar, which was merely a structure for sacred use, was nothing more than a hearth, whereon the victim was prepared for the meal ; and it was not till long after Homer's time that a regular priesthood appeared in Greece. In Sparta, the kings performed the office. In Egypt, the dignity was obtained by inheritance ; as was the case in other places. The *Odyssey* places the altar in the king's palace ; and we may reasonably assume that the spot was occasionally, perhaps always, used as the temple. From such premises, it is reasonable to conjecture that until the sacerdotal was separated from the kingly office, the temple, either in Greece or elsewhere, had no existence. It may not be without interest to collect, here, the different passages in the *Odyssey*, which bear upon the nature and construction of the very earliest buildings of importance. Between the *αὐλή* and the *δομος* there must have been a distinction. The former, from its etymology *αὐ*, must have been a *locus subdialis* ; and though it is sometimes used (*Iliad*, Z. 247.) for the whole palace, such is not generally its meaning in the *Odyssey*. The *αὐλή* was the place in which the female attendants of Penelope were slain by Telemachus (*Odys.* X. 446.), by tying them up with a rope over the *δολος* or ceiling. Hence we arrive at the conclusion that this *δολος* belonged to the *αἶθουσα* or cloister, supposing, as we have done, that the *αὐλή* was open at top, and the *αἶθουσα* is described (*Iliad*, T. 176.) as *εἰδονπος*, that is, sonorous or echoing, and as circumscribing the open part of the *αὐλή*. The *δολος* was supported by *κίονες*, posts or columns, and in the centre of the *αὐλή* stood the *βομος* or altar. If our interpretation be correct, the *μεσοδομαί* in this arrangement must be the spaces between the columns or posts, or the intercolumniations, as the word is usually translated ; and the passage in the *Odyssey* (T. 37.), wherein Telemachus is said to have seen the light on the walls, becomes quite clear. The passage is as follows :—

Εἰπαὶς μὲν ταῖσιν μέγαρον, καλαὶ δὲ μεσοδομαί,  
Εἰλατῖναι τε δομοὶ, καὶ κίονες ὑψοῦς ἔχοντες,  
Φαινέσθ' οὐρανόθεν.

There seems no doubt that the word *αἶθουσα* will bear the interpretation given, and the arrangement is nothing more than that of the hypæthral, and even correspondent with the Egyptian temple, particularly that of the temple at Edfou, described by Denon, and represented in his plate 34.

138. Before we quit this part of our subject, let us consider the description which Homer (*Odys.* H. 81.) gives of the house of Alcinoüs as illustrative of Greek architecture. This dwelling, which Ulysses visited, had a brazen threshold, *οὐδος*. It was *υπερέφης* or

lofty-roofed. The walls were brazen on every side, from the threshold to the innermost part. This, however, is rather poetic. The coping *δρυκος* was of a blue colour. The interior doors are described as gold. The jambs of them, *σθαβοι*, were of silver on a brazen threshold. The lintel *υπερθυριον* was silver, and the cornice *κορωνη* of gold. Statues of dogs, in gold and silver, which had been curiously contrived by Vulcan himself, guarded the portal. Thus far, making all due allowance for the poet's fancy, we gain an insight into what was considered the value of art in his day, more dependent, it would seem, on material than on form. Seats seemed to have been placed round the interior part of the house, on which seats were cushions, which the women wrought. But we must return to the construction of the *αυλη*, inasmuch as in it we find considerable resemblance to the rectangular and columnar disposition of the comparatively more recent temple.

139. It would be a hopeless task to connect the steps that intervened between the sole use of the altar and the establishment of the temple in its perfection; though it might, did our limits permit the investigation, be more easy to find out the period when the regular temple became an indispensable appendage to the religion of the country. It is closely connected with that revolution which abolished the civil, judicial, and military offices of kings leaving the sacerdotal office to another class of persons. Though in the palace of the king no portion of it was appropriated to religious ceremony, the spot of the altar only excepted, yet, as it was the depository of the furniture and utensils requisite for the rite of sacrifice, when the palace was no more, an apartment would be wanting for them; and this, conjoined with other matters, may have suggested the use of the cell. Eusebius has conjectured that the temple originated in the reverence of the ancients for their departed relations and friends, and that they were only stately monuments in honour of heroes, from whom the world had received considerable benefit, as in the case of the temple of Pallas, at Larissa, really the sepulchre of Acrisius, and the temple of Minerva Polias at Athens, which is supposed to cover the remains of Erichthonius. The passage in Virgil (*Æn.* ii. v. 74.)—

—— tumulum antiquæ Cereris, sedemque sacratam  
Venimus —

is explanatory of the practice of the ancients in this respect; and, indeed, it is well known that sacrifices, prayers, and libations were offered at almost every tomb; nay, the resting-place of the dead was an asylum or sanctuary not less sacred than was, afterwards, the temple itself. From Strabo (lib. ii.) it is clear that the temple was not always originally a structure dedicated to a god, but that it was occasionally reared in honour of other personages.

140. Before proceeding to that which is more accurately known, it may not be unstructive to the reader to glance at the houses of the Greeks, as may be gathered from passages in the *Iliad* and the *Odyssey*. We shall merely remind him that Priam's house had fifty separate chambers, though he lived in a dwelling apart from it. These houses were, in some parts, two stories in height, though the passages supporting that assertion (*Iliad*, B. 514–16. 184.) have been pronounced of doubtful antiquity. There is, however, not the slightest doubt that the dwellings of the East consisted of more than a single story. David wept for Absalom in the chamber *over* the gate (2 *Sam.* xviii. 33.). The altars of Abaz were on the terrace of the *upper chamber* (3 *Kings*, xxiii. 12.). The summer chamber of Eglon had *stairs* to it, for by them Ehud escaped, after he had revenged Israel (*Judges*, iii. 20.; 1 *Kings*, vi. 8.). In the Septuagint, these upper stories are all represented by the word *υπερσωον*, the same employed by Homer. The Jewish law required (*Deut.* xxii. 8.) the terraces on the tops of their houses to be protected by a battlement; and, indeed, for want of a railing (*Odys.* K. 552. et seq.) of this sort, Elpenor, one of the companions of Ulysses, at the palace of Circe, fell over and broke his neck. The use of the word *κλιμαξ* in the *Odyssey*, connected with the words *αναβαινειν* and *καταβαινειν*, and the substantive *υπερσωον*, is of frequent occurrence: it is either a ladder or a staircase, and which of them is unimportant; but it clearly indicates an upper story. To a comparatively late period, the Greek temple was of timber. Even statues of the deities were, in the time of Xenophon, made in wood for the smaller temples (lib. iv. c. 1.), where the revenue of them was not adequate to afford a more expensive material. But time and accidents would scarcely permit their prolonged duration, and none survived long enough to allow of a proper description of them reaching us. The principle of their construction necessarily bore some relation to the materials employed, and the use of stone must have imparted new features to them. In timber, the beam (*epistylum*), which was borne by the columns, would probably extend in one piece through each face of the building. But in a stone construction this could not take place, even had blocks of such dimensions been procurable, and had mechanical means been at hand to place them in their proper position. From this alone follows a diminution of spaces between the columns. The arch, be it recollected, was unknown. It is curious to observe that the relative antiquity of the examples of Grecian Doric may be expressed in terms of the intercolumniations; that is, the number of diameters forming the intervals between the columns. There is, moreover, another point worthy of notice, which is, that their antiquity may be also estimated by the comparison of the heights of the columns compared with their diameters. This, however, will require

further consideration when we come to treat of the orders: here it is noticed only incidentally. Though we are not inclined to place reliance on the account given by Vitruvius of the origin of the orders of architecture, we should scarcely be justified in its omission here. It seems necessary to notice it in any work on architecture; and, after remarking that the age which that author assigns for their origin is long before Homer's time, at which there seems no probability of their existence, from the absence of all reference to them in his poems, we here subjoin the account of Vitruvius (lib. iv. c. 1.):—"Dorus, son of Hellen and the Nymph Orseis, reigned over Achaia and Peloponnesus. He built a temple of this (the Doric) order, on a spot sacred to Juno, at Argos, an ancient city. Many temples similar to it were afterwards raised in the other parts of Achaia, though, at that time, its proportions were not precisely established. When the Athenians, in a general assembly of the states of Greece, sent over into Asia, by the advice of the Delphic oracle, thirteen colonies at the same time, they appointed a governor over each, reserving the chief command for Ion, the son of Xuthus, and Creusa, whom the Delphic Apollo had acknowledged as son. He led them over into Asia, where they occupied the borders of Caria, and built the great cities of Ephesus, Miletus, Myus (afterwards destroyed by inundation, and its sacred rites and suffrages transferred by the Ionians to the inhabitants of Miletus), Priene, Samos, Teos, Colophon, Chios, Erythrae, Phocæa, Clazomene, Lebedos, and Melite. This last, as a punishment for the arrogance of its citizens, was detached from the other states in the course of a war levied on it, in a general council, and in its place, as a mark of favour towards king Attalus and Arsinoe, the city of Smyrna was received into the number of the Ionian states. These received the appellation of Ionian, after the Carians and Lelegæ had been driven out, from the name of Ion, the leader. In this country, allotting different sites to sacred purposes, they erected temples, the first of which was dedicated to Apollo Panionius. It resembled that which they had seen in Achaia, and from the species having been first used in the cities of Doria, they gave it the name of Doric. As they wished to erect this temple with columns, and were not acquainted with their proportions, nor the mode in which they should be adjusted, so as to be both adapted to the reception of the superincumbent weight, and to have a beautiful effect, they measured a man's height by the length of the foot, which they found to be a sixth part thereof, and thence deduced the proportions of their columns. Thus the Doric order borrowed its proportion, strength, and beauty from the human figure. On similar principles, they afterwards built the temple of Diana; but in this, from a desire of varying the proportions, they used the female figure as a standard, making the height of the column eight times its thickness, for the purpose of giving it a more lofty effect. Under this new order, they placed a base as a shoe to the foot. They also added volutes to the capital, resembling the graceful curls of the hair, hanging therefrom, to the right and left, certain mouldings and foliage. On the shaft, channels were sunk, bearing a resemblance to the folds of a matronal garment. Thus were two orders invented; one of a masculine character, without ornament, the other of a character approaching the delicacy, decorations, and proportions of a female. The successors of these people, improving in taste, and preferring a more slender proportion, assigned seven diameters to the height of the Doric column, and eight and a half to the Ionic. That species, of which the Ionians were the inventors, has received the appellation of Ionic. The third species, which is called Corinthian, resembles, in its character, the graceful elegant appearance of a virgin, whose limbs are of a more delicate form, and whose ornaments should be unobtrusive. The invention of the capital of this order arose from the following circumstance. (Fig. 93.) A Corinthian virgin, who was of marriageable age, fell a victim to a violent disorder: after her interment, her nurse, collecting in a basket those articles to which she had shown a partiality when alive, carried them to her tomb, and placed a tile on the basket, for the longer preservation of its contents. The basket was accidentally placed on the root of an acanthus plant, which, pressed by the weight, shot forth, towards spring, its stems and large foliage, and in the course of its growth, reached the angles of the tile, and thus formed volutes at the extremities. Callimachus, who, for his great ingenuity and taste in sculpture, was called by the Athenians *καταρχος*, happening at this time to pass by the tomb, observed the basket and the delicacy of the foliage that surrounded it. Pleased with the form and novelty of the combination, he took the hint for inventing these columns, using them in the country about Corinth," &c. Now, though we regret to damage so elegant and romantic a story, we must remind those who would willingly trust the authority we have quoted, that Vitruvius speaks of matters which occurred so long before his time, that in such an investigation as that before us we must have other authentication than that of the author we quote, and most especially in the case of the Corinthian capital, whose type may be referred to in a

FIG. 93. ORIGIN OF CORINTHIAN CAPITAL.

and the delicacy of the foliage that surrounded it. Pleased with the form and novelty of the combination, he took the hint for inventing these columns, using them in the country about Corinth," &c. Now, though we regret to damage so elegant and romantic a story, we must remind those who would willingly trust the authority we have quoted, that Vitruvius speaks of matters which occurred so long before his time, that in such an investigation as that before us we must have other authentication than that of the author we quote, and most especially in the case of the Corinthian capital, whose type may be referred to in a

vast number of the examples of Egyptian capitals, one of which, among many, is seen in *fig. 94*.

Fig. 94. EGYPTIAN CAPITAL.

141. The progress of the art in Greece, whose inhabitants, in the opinion of the Egyptian priests in the time of Solon, were so ignorant of all science that they neither understood the mythology of other nations nor their own (Plato, in *Timæo*), cannot be satisfactorily followed between the period assigned to the siege of Troy and the time of Solon and Pisistratus, or about 590 B. C. But it is, however, certain that within four centuries after Homer's time, notwithstanding their originally coarse manners, the Grecians attained the highest excellence in the arts. Goguet is of opinion the nurture of the art was principally in Asia Minor, in which country, he thinks, we must seek for the origin of the Doric and Ionic orders, whilst in Greece Proper the advancement was slow. The Corinthian order was, however, the last invented, and it seems generally agreed that its invention belongs to the mother country; but this we shall not stop to discuss here. The Temple of Jupiter, at Olympia, one of the earliest temples of Greece (Pausanias, *Eliac. Pr.* c. 10.), was built about 630 years before the Christian era; and after this period were reared temples at Samos, Priene, Ephesus, and Magnesia, and other places up to that age when, under the administration of Pericles, the architecture of Greece attained perfection, and the highest beauty whereof it is supposed to be susceptible, in the Parthenon (*fig. 95*.)

Fig. 95.

VIEW OF THE PARTHENON.

at Athens. The date of the erection of the temple of Diana, at Ephesus, was really as remote as that of the temple we have just mentioned. If Livy had sufficiently our confidence, and we concede that other writers corroborate his statement (*lib. i. c. 45.*), its date is as ancient as the time when Servius Tullius was king of Rome. Great, however, as were the works which the Grecians executed, the mechanical powers were, if one may judge from Thucydides (*lib. iv.*), not compendiously applied for raising weights.

142. The origin of the Doric order is a question not easily disposed of. Many provinces of Greece bore the name of Doria; but a name is often the least satisfactory mode of accounting for the birth of the thing which bears it. We have already attempted to account for the parts of this order by a reference to its supposed connection with the hut. The writer, in the *Encyclopédie Méthodique*, truly says that if the Doric had an *inventor*, that inventor was a people whose wants were, for a long period, similar, and with whom a style of building prevailed suitable to their habits and climate, though but slowly modified and carried to perfection. At the beginning of this section, we have, however, sufficiently spoken on this matter. But there are some peculiarities to be noticed with respect to the Doric order, which we think will be better given here than in the third book, where we propose to treat of the orders more fully; and these consist in the great differences which are found in its proportions and parts in different examples. For this purpose, several buildings have been arranged in the following table, wherein the first column exhibits the name of the building; the second the height of the column, of the example as a nume-

rator, and its lower diameter as a denominator, both in English feet; the third is the quotient of the second, showing the height of the column, expressed in terms of its lower diameter; the fourth column shows the height of the entablature in terms of the diameter of the column; the fifth column gives the distance between the columns in the same terms; and the sixth shows the height of the capitals also in the same terms:—

Example.	Height divided by lower Diameter in English Feet.	Diameters high.	Height of Entablature in Terms of Diameter.	Interco- lumnations.	Height of Capital in terms of Diameter.
Temple at Corinth - - - -	$\frac{23.713}{5.83} =$	4.065	.	1.362	.405
Hypæthral Temple at Pæstum - -	$\frac{28.950}{7.00} =$	4.134	1.741	1.167	.549
Enneastyle Temple at Pæstum . -	$\frac{21.000}{4.85} =$	4.329	1.140	1.064	.500
Greater Hexastyle Temple at Selinus -	$\frac{32.678}{7.49} =$	4.361	2.200	1.490	.490
Temple of Minerva at Syracuse - -	$\frac{28.665}{6.50} =$	4.410	.	.	.486
Octastyle Hypæthral Temple at Selinus -	$\frac{48.585}{10.62} =$	4.572	2.038	1.023	.450
Temple of Juno Lucina at Agrigentum -	$\frac{21.156}{4.59} =$	4.605	.	.	.570
Temple of Concord at Agrigentum -	$\frac{22.062}{4.64} =$	4.753	1.976	1.071	.487
Hexastyle Temple at Pæstum - -	$\frac{20.383}{4.24} =$	4.795	1.917	1.111	.564
Temple of Jupiter Panhellenius at Egina -	$\frac{17.354}{3.22} =$	5.395	.	1.680	.486
Parthenon - - - -	$\frac{34.232}{6.15} =$	5.566	1.977	1.275	.459
Temple of Theseus at Athens - -	$\frac{18.717}{3.30} =$	5.669	1.964	1.250	.502
Temple of Minerva at Sunium - -	$\frac{19.762}{3.34} =$	5.899	1.928	1.472	.372
Doric Portico of Augustus at Athens -	$\frac{26.206}{4.33} =$	6.042	1.724	1.046	.374
Temple of Apollo, Island of Delos -	$\frac{18.721}{3.0.2} =$	6.052	1.900	1.500	.555
Temple of Jupiter Nemeus - - -	$\frac{33.932}{5.22} =$	6.515	1.560	1.348	.383
Portico of Philip of Macedon - -	$\frac{19.330}{2.96} =$	6.535	1.867	2.700	.480

143. Casting our eye down the third column of the above table, we find the height of the column in terms of its lower diameter varying from 4.065 to 6.535. Lord Aberdeen (*Inquiry into the Principles of Beauty in Greek Architecture*, 1822) seems to prefer the proportion of the capital to the column, as a test for determining its comparative antiquity; but we are not, though it is entitled to great respect, of his opinion, preferring, as we do, a judgment from the height as compared with the diameter to any other criterion; although it must be admitted that it is not an infallible one. The last columns shows what an inconstant test the height of the capital exhibits. There is another combination, to which reference ought to be made,—the height of the entablature, which forms the third column of the table, in which it appears that the most massive is about one third the height of the whole order, and the lightest is about one fourth, and that these proportions coincide with the thickest and the thinnest columns.

144. The entasis or swelling, which the Greeks gave to their columns, and first verified by the observations of Mr. Allason, was a refinement introduced probably at a late period, though the mere diminution of them was adopted in the earliest times. The practice is said to have its type in the law which Nature observes in the formation of the trunks of trees. This diminution varies, in a number of examples, from one fifth to one third of the lower diameter; a mean of sixteen examples gives one fourth. The mere diminution is not, however, the matter for consideration; but the curved outline of the shaft, which is attributed to some refined perception of the Greeks,

relative to the apparent diminution of objects as their distance from the eye was increased, which Vitruvius imagines it was the object of the entasis to correct. It cannot be denied that in a merely conical shaft there is an appearance of concavity, for which it is difficult to account. The following explanation of this phenomenon, if it may be so called, is given by our esteemed and learned friend, Mr. Narrien, in the *Encyc. Metropol. art. Architecture*. "When," he observes, "we direct the axis of the eye to the middle of a tall column, the organ accommodates itself to the distance of that part of the object, in order to obtain distinctness of vision, and then the oblique pencils of light from the upper and lower parts of the column do not so accurately converge on the retina: hence arises a certain degree of obscurity, which always produces a perception of greater magnitude than would be produced by the same object if seen more distinctly. The same explanation may serve to account for the well-known fact, that the top of an undiminished pilaster appears so much broader than the body of its shaft; to which, in this case, may be added some prejudice, caused by our more frequently contemplating other objects, as trees, which taper towards their upper extremities." Connected in some measure with the same optical deception is the rule which Vitruvius lays down (book iii. chap. 2.) for making the columns, at the angles of buildings, thicker than those in the middle by one fiftieth part of a diameter,—a law which we find followed out to a much greater extent in the temples of the Parthenon and of Theseus, at Athens, where the columns at the angles exceed in diameter the intermediate ones by one forty-fourth and one twenty-eighth respectively. Where, however, the columns were viewed against a dark ground, some artists think that a contrary deception of the eye seems to take place.

145. In the investigation of the Doric order, among its more remarkable features are to be noted the longitudinal striæ, called *flutes*, into which the column is cut; every two whereof unite, in almost every case, in an edge. Their horizontal section varies in different examples. In some, the flutes are formed by segments of circles; in others, the form approaches that of an ellipsis. The number all round is usually twenty; such being the case at Athens; but at Pæstum the exterior order of the great temple has twenty-four, the lower interior order twenty, and the upper interior sixteen only. It has been strangely imagined, by some, that these flutings, which, be it remembered, are applied to the other orders as well as to the Doric, were provided for the reception of the spears of persons visiting the temples. The conjecture is scarcely worth refutation, first, because no situation for the *δωροδοκη* (place for spears) would have led to their more continual displacement from accident; and secondly, because of the sloping or hemispherical form in the other orders, the foot of the spear must have immediately slid off. Their origin may probably be found in the polygonal column, whose sides received a greater play of light by being hollowed out,—a refinement which would not be long unperceived by the Greeks.

146. We shall now notice some of the more important Doric edifices, as connected with the later history of the Doric order, which was that most generally used by the European states of Greece, up to their subjugation by the Romans. The temple of Jupiter Panhellenius, at Egina, is probably one of the most ancient in Greece. The story, however, of Pausanias, that it was built by Æacus, before the war of Troy, is only useful as showing us its high antiquity. (Fig. 96.) The proportions of its columns and entablature are to be

Fig. 96.

RECONSTRUCTION OF THE TEMPLE OF JUPITER PANTHELIENIUS.

found in a preceding page. The sculpture with which this building was decorated is now at Munich. Though, perhaps, not so old as the building itself, it is of an antiquity coeval with the Persian invasion. The name of the architect of this temple was Libon, of whom no other work is known; its age is, perhaps, from about 600 years before Christ. The Doric temple at Corinth, of which five columns, with their architrave, are still in existence, is a very early specimen of Grecian architecture. The assertion that it was dedicated to Venus is unsupported by testimony.

147. The Grecian temples in Sicily were erected at periods which it is not easy to fix; and with respect to them, we can only, from circumstances connected with the island, reason on the dates to be assigned to them. The founding of the city of Selinus or Selinuns, on the south-west coast of the island, has usually been attributed to a colony from Megara; but we are of opinion with the Baron Pisani (*Memoria sulle Metope Selinuntine*) that it existed as a Phœnician city long previous to the settlement there by the Megaræans. The style and forms of the sculpture of the Selinuntine temples seem to bear marks of a remoter age than is usually allowed to them, that is, 500 years B. C. Of the means and the circumstances under which they were raised we are ignorant; but their ruins sufficiently indicate the wealth and power that were employed upon them, as well as a considerably advanced state of the art.

148. The temple of Jupiter Olympius, the largest in the island, and one of the most stupendous monuments of antiquity, was, as we learn from Diodorus (lib. xiii. p. 82.), never completed. The Agrigentines were occupied upon it when the city was taken by Hamilcar, in the 93d Olympiad. Its columns were on such a scale that their flutes were sufficiently large to receive the body of a man. The temples of Peace and of Concord, in the few vestiges that remain of them, attest the ancient magnificence of the city of Agrigentum, and are among the most beautiful as well as the best preserved remains of antiquity. A Corinthian colony established itself at Syracuse, as is said, 750 B. C.; but no details of the history of the city furnish us with the means of ascertaining when the first temples there were erected. Its riches and magnificence were, however, such that it soon became an object of temptation to the Carthaginians. Its temple of Minerva is evidently of very remote antiquity.

149. The great Hypæthral temple at Pæstum was probably constructed during the period that the city was under the power of the Sybarites, who dispossessed its original inhabitants, enjoying, for upwards of two hundred years, the fruits of their usurpation. Marks of Greek art are visible in it, and the antiquity of the Hypæthral temple itself is confirmed by the example. The city fell into the hands of the Lucanians about 350 years B. C.; after which, in about 70 years, it was a municipal town of the Roman empire. The following is perhaps the chronological order of the principal buildings of Sicily and Magna Græcia; viz. Syracuse, Pæstum, Selinus, Segesta, and Agrigentum.

150. The dates of the edifices at Athens are, without difficulty, accurately fixed. The Propylæum (*figs. 97 and 98.*) was commenced by Mnesicles about 437 B. C., and, at a great

Fig. 97.

PLAN OF PROPYLÆUM.

Fig. 98.

ELEVATION OF THE PROPYLEUM.

expense, was completed in five years. It is a specimen of the military architecture of the period, and at the same time forms a fine entrance to the Acropolis of Athens. At the rear of its Doric portico the roof of the vestibule was supported within by two rows of Ionic columns, whose bases still remain. By the introduction of these an increased height was obtained for the roof, the abaci of the Ionic capitals being thus brought level with the ex-

Fig. 99.

 50 ft  
 PLAN OF THE PARTHENON.

terior frieze of the building. The Parthenon (*figs. 99. and 100.*) erected a few years later, under the superintendence of Ictinus, is well known as one of the finest remains of antiquity.

Fig. 100.

ELEVATION OF THE PARTHENON.

As well as the building last mentioned, it was reared at the period when Pericles had the management of public affairs, and was without a rival in Athens. Phidias was the superintendent sculptor employed; and many of the productions which decorated this magnificent edifice have doubtless become known to the reader in his visits to the British Museum, where a large portion of them are now deposited. Nearly coeval with the Propylæum and Parthenon, or perhaps a little earlier, is the temple of Theseus (*fig. 101.*), which was, it is supposed, erected to receive the ashes of the national hero, when removed from Scyros to Athens. The ruins of the architectural monuments of this city attest that the boasted power and opulence of Greece was not an idle tale. Pericles, indeed, was charged by his enemies with having brought disgrace upon the Athenians by removing the public trea-

sures of Greece from Delos, and lavishing them in gilding

their city, and ornamenting it with statues and temples that cost a thousand talents, as a proud and vain woman tricks herself out with jewels. (*Plutarch's Life of Pericles.*) The temple of Minerva, at Sunium, was probably by Ictinus; but one of the happiest efforts of this architect was the temple of Apollo Epicurius, in Arcadia, still nearly entire. The peculiarities found in it we will shortly detail. The front has six columns, and instead of thirteen in each flank (the usual number) there are fifteen. In the interior, buttresses on each side, to the number of six, return

Fig. 101.

TEMPLE OF THESEUS.

inwards from the walls of the cell, each ending in semicircular pilasters of the Ionic order. These seem to have been brought up for the facility of supporting the roof, which was of stone. With the exception of the temple of Minerva at Tegea, its reputation for beauty was such, that it surpassed, if that be a true test, all other buildings in Peloponnesus. Its situation is about three or four miles from the ruins of Phigalia, on an elevated part of Mount Cotelus, commanding a splendid landscape, which is terminated by the sea in the distance.

151. About 370 B.C., Epaminondas restored the Messenians to independence, and built the city of Messene. The ruins still extant prove that the art at that period had not materially declined. Its walls, in many parts, are entire, and exhibit a fine example of Grecian military architecture in their towers and gates. At no distant time from the age in question the portico of Philip of Macedon, at least his name is inscribed on it, shows that the Doric order had undergone a great change in its proportions. This portico must have been erected about 338 B.C., and after it the Ionic order seems to have been more favoured and cultivated. The last example of the Doric is perhaps the portico of Augustus, at Athens.

152. Before proceeding to the investigation of the Ionic order, it may here, perhaps, be as well to speak of the proportions between the length and breadth of temples, as compared with the rules given by Vitruvius (book iv. chap. 4.), that the length of a temple shall be double its breadth, and the cell itself in length one fourth part more than the breadth, including the wall in which the doors are placed. Though in the Greek examples these proportions are approximated, an exact conformity with the rule is not observed in any. The length, for instance, of the temple of Jupiter, at Selinus, is to the breadth as 2.05 to 1; in the temple of Theseus, as 2.3 to 1; and from the mean of six examples of the Doric order, selected in Greece and Sicily, is 2.21 to 1. If the flanks be regulated in length by making the number of intercolumniations exactly double those in front, it will be immediately seen that the proportions of Vitruvius are obtained on a line passing through the axes of the columns. But as in most of the Greek temples the central intercolumniation in front is wider than the rest, the length of the temple would necessarily be less than twice the width. In the earlier specimens of the Doric order the length is certainly, as above mentioned in the temple of Jupiter at Selinus, very nearly in accordance with the rule; but in order to counteract the effect of the central intercolumniation being wider, the number of columns, instead of intercolumniations on the flank, is made exactly double those in front. In the later examples, however, as in the temples of Theseus and the Parthenon, and some others, the number of intercolumniations on the flank was made double the number of columns in the front, whence the number of columns on the flanks was double the number of those in front and one more; so that the proportion became nearly in the ratio of 2.3 to 1. The simplicity which flowed from these arrangements in the Grecian temples was such that it seems little more than arithmetical architecture,—so symmetrical that from the three data, the diameter of the column, the width of the intercolumniation, and the number of columns in front, all the other parts might be found.

153. The Ionic order, at first chiefly confined to the states of Asia Minor, appears to have been coeval with the Doric order. The most ancient example of it on record is the temple of Juno, at Samos. Herodotus (*Euterpe*) says, it was one of the most stupendous edifices erected by the Greeks. In the *Ionian Antiquities* (2d edit. vol. i. c. 5.) is to be found an account of its ruins. It was erected about 540 years B.C., by Rhæacus and Theodorus, two natives of the island. The octastyle temple of Bacchus, at Teos, in whose praise Vitruvius was lavish, shows by its ruins that the old master of our art was well capable of appreciating the beauties of an edifice. Hermogenes, of Alabanda, was its architect, and he seems to have been the promoter of a great change in the taste of his day. Vitruvius

(lib. iv. c. 3.) tells us that Hermogenes, "after having prepared a large quantity of marble for a Doric temple, changed his mind, and, with the materials collected, made it of the Ionic order, in honour of Bacchus." We are bound, however, to observe upon this, that the story is not confirmed by any other writer. It is probable that this splendid building was raised after the Persian invasion; for, according to Strabo (lib. xiv.), all the sacred edifices of the Ionian cities, Ephesus excepted, were destroyed by Xerxes. Besides this octastyle temple, those of Apollo Didymæus, near Miletus, built about 376 a.c., and of Minerva Polias, at Priene, dedicated by Alexander of Macedon, are the chief temples of this order of much fame in the colonies. We shall therefore confine our remaining remarks to the three Ionic temples at Athens, and shall, as in the Doric order, subjoin a synoptical view of their detail.

Example.	Height divided by lower Diameter, in English Feet.	Diameter high.	Height of Entablature in terms of Diameter.	Interco- lumnations.	Height of Capital in terms of Diameter.	Upper Diameter, lower Diam. being 1·000.
Temple on the Ilyssus -	$\frac{14\ 694}{1\ 783} =$	8 241	2·265	2·090	0·610	·850
Temple of Minerva Polias -	$\frac{25\ 387}{2\ 786} =$	9 119	2·287	3·500	0·700	·633
Temple of Erectheus -	$\frac{21\ 625}{2\ 317} =$	9 337	.	2·000	0·773	·816

154. We here see that the Ionic column varies in height from eight diameters and nearly a quarter to nearly nine and a half, and the upper diameter in width between  $\frac{85}{100}$  and  $\frac{816}{1000}$ . The dissimilarity of the capitals renders it impossible to compare them. The mean height of the entablature is about a fourth of the height of the whole order. The height of the Grecian Ionic cornice may be generally considered as two-ninths of the whole entablature.

155. The age of the double temple of Minerva Polias (*fig. 102.*) and Erectheus has

Fig. 102.

TEMPLE OF MINERVA POLIAS AND ERECTHEUS.

not been accurately ascertained. From the earliest times these personages were held in high veneration by the Athenians, and it is more than likely that a confusion has arisen between the ancient and modern edifices. The former was partially destroyed by Xerxes, and there is no certainty that the latter was restored by Pericles.

156. In the bases applied to the order in the Athenian buildings there are two *tori*, with a *scotia* or *trochilus* between them, a fillet below and above the scotia separating it from the tori. The lower fillet generally coincides with a vertical line let fall from the extreme projection of the upper torus. In the temple on the Ilyssus the lower fillet projects about half the distance between the hollow of the scotia and the extremity of the inferior torus. The height of the two tori and scotia are nearly equal, and a bead is placed on the upper

torus for the reception of the shaft of the column. The temples of Erechtheus and that on the Ilyssus have the lower tori of their bases uncut, whilst the upper ones are fluted horizontally. In that of Minerva Polias, the upper torus is sculptured with a *guilloche*. The base just described is usually denominated the *ATTIC BASE*, though also used in the colonies. The bases, however, of the temples of Minerva Polias at Priene, and of Apollo Didymæus near Miletus, are very differently formed.

157. The *VOLUTE*, the great distinguishing feature of the order, varies considerably in the different examples. In the edifices on the Ilyssus and at Priene, as well as in that of Apollo Didymæus, the volute has only one channel between the revolutions of the spiral; whilst in those of Erechtheus and Minerva Polias, at Athens, each volute is furnished with two distinct spirals and channels. In the temple on the Ilyssus, the capital is terminated a little below the eye of the volute; in the others it reaches below the volutes, and is decorated with honeysuckle flowers and foliage. The number of flutes, which on the plan are usually elliptical, is twenty-four, and they are separated by fillets from each other. In some examples they descend into the apophyge of the shaft.

158. The tomb of Theron, at Agrigentum, in which Ionic columns and capitals are crowned with a Doric entablature, has, by some, been quoted as an example of the Ionic order; but we do not believe it to be of any antiquity, and, if it were, it is so anomalous a specimen that it would be useless to pursue any inquiry into its foundation.

159. In the *antæ* or pilasters of this order, as well as of the Doric, their capitals differ in profile from the columns, and are never decorated with volutes. Their breadth is usually less than a diameter of the column, and they are not diminished.

160. The highest degree of refinement of Greek architecture is exhibited in its examples of the Corinthian order, whose distinguishing feature is its capital. We have, in a preceding page (139), given Vitruvius's account of its origin; but we much doubt whether Callimachus was its inventor.

161. The capitals of Egyptian columns are so close upon the invention, that we apprehend it was only a step or two in advance of what had previously been done. The palm leaf, lotus flower, and even volutes, had been used in similar situations in Egypt, and the contour of the lotus flower itself bears no small resemblance to the bell of the Corinthian capital.

162. We are inclined to assign the period of the latter part of the Peloponnesian war as that in which the order first came into use. We find from Pausanias (*Arcead.* c. 45.) that Scopas, the celebrated architect of Paros, rebuilt the temple of Minerva at Tegæa, which was destroyed by fire about 400 years B.C., and that, according to that author, it was the largest and most beautiful edifice in the Peloponnesus. The cell, which was hypæthral, was surrounded by two ranks of Doric columns, which were surmounted by others of the Corinthian order. The peristyle of this temple was Ionic.

163. The delicacy of formation of this order has, doubtless, subjected its examples to earlier destruction and decay than have attended the other orders: hence our knowledge of it is almost confined to the examples we meet of it in the Tower of the Winds, and the Choragic monument of Lysicrates (*fig.* 103.), both at Athens; the former whereof can scarcely be considered Corinthian, and the latter not very strictly so. It was erected about 330 years B.C., as appears from the inscription on the frieze. These Choragic buildings, usually of small dimensions, were erected in honour of those who, as choragi or leaders of the chorus in the musical games, were honoured with the prize, which was a tripod. The following are the proportions observed in the Choragic monument of Lysicrates:—

FIG. 103. CHORAGIC MONUMENT OF  
LYSICRATES.

Height of columns in English feet	11·637
Height of columns in terms of lower diameter	10·318
Height of capital in terms of lower diameter	1·216
Upper diameter of shaft in terms of the lower diameter	0·833
Height of the architrave in terms of the lower diameter	0·850
Height of the frieze in terms of the lower diameter	0·483
Height of cornice in terms of the lower diameter	0·833

Total height of entablature in terms of the lower diameter 2 166

From which it appears that the entablature is less than a fifth of the total height of the order. The intercolumniations are 2·200 diameters. The base is little different from that used in the Ionic order.

164. In the ornaments applied for the decoration of the sacred edifices of the Greeks,  
F 3

they imitated the real and symbolical objects used in their worship. Thus, at the temple of Apollo at Teos, the lyre, tripod, and griffin occur; in the Temple of the Winds at Athens, the winds are personified on the walls; the Choragic monument of Lysicrates exhibits the consequences of a contempt of music; on the temple of Victory, at the entrance of the Acropolis, was recorded, on the very spot, the assault and repulsion of the Amazons; the Lapithæ are vanquished again in the temple of Theseus, the founder of the city; and lastly, in the Parthenon is brought before the eye, on a belt round the cell of the temple, the Panathenæic procession, which, issuing from the door of the cell, biennially perambulated the edifice, whilst its pediment perpetuates the contest between Neptune and Minerva for the honour of naming the city, and calls to remembrance the words of Cicero, "De quorum," (Atheniensium,) "urbis possessione, propter pulchritudinem etiam inter deos certamen fuisse proditum est," &c. In the capitals of the Corinthian examples just noticed the leaves are those of the olive, a tree sacred to the tutelary goddess of Athens, and on that account as well as its beauty of form and simplicity adopted by a people whose consistency in art has never been excelled.

165. Besides the method of supporting an entablature by means of columns, the employment of figures was adopted, as in the temples of Erectheus and Minerva Polias before mentioned (see fig. 102.). They were called *Caryatides*; and their origin, according to the account of it by Vitruvius (lib. i. c. 1.), was that Caryæ, a city of Peloponnesus, having assisted the Persians against the Grecian states, the latter, when the country was freed from their invaders, turned their arms against the Caryans, captured their city, put the males to the sword, and led the women into captivity. The architects of the time, to perpetuate the ignominy of the people, substituted statues of these women for columns in their porticoes, faithfully copying their ornaments and drapery. It is, however, certain that the origin of their application for architectural purposes is of far higher antiquity than the invasion of Greece by the Persians, and in the above account Vitruvius is not corroborated by any other writer. Herodotus (*Polymnia*), indeed, observes that some of the states whom he enumerates sent the required offering of salt and water to Xerxes; but no mention is made of Caryæ, whose conduct, if punished in such an extraordinary manner, would have been too curious a matter to have been passed over in silence. Whether the use of statues to perform the office of columns travelled into Greece from India or from Egypt, we will not pretend to determine. Both, however, will furnish examples of their application. In the latter country we find them employed in the tomb of King Osymandyas (*Diodorus*, tom. i. f. 56. Wesseling). Diodorus also, speaking of Psammeticus, says that having obtained the whole kingdom, he built a propylæum on the east side of the temple to the god at Memphis, which temple he encircled with a wall; and in this propylæum, instead of columns, substituted colossal statues (*κολοσσούς ὑποστήσας*) twelve cubits in height.

166. The application of statues and representations of animals is a prominent feature in the architecture of Egypt, whereof the temple at Ibsambul is a striking example, though in that the figures do not absolutely carry the entablature (see fig. 71.). In India many instances of this use of statues occur, as in the excavations of the temple near Vellore described by Sir C. Mallet (*Asiat. Res.* vol. vi.), wherein heads of lions, elephants, and imaginary animals apparently support the roof of the cave of Jugnath Subba; and at Elephanta, where colossal statues are ranged along the sides as high as the underside of the entablature (see fig. 39.). But as the settlement of the claims of either of these countries to the invention is not our object, we shall proceed to consider how they obtained in Greece the name that has been applied to them long before the period of which Vitruvius speaks.

167. *Karpha*, the nut tree (*Nux juglans*), which Plutarch (*Sympos.* lib. ii.) says received its name from its effect (*κάρπος*, *sopor*) on the senses, was that into which Bacehus, after cohabitation with her, transformed Caryæ, one of the three daughters of Dion, king of Laconia, by his wife Iphitea. The other daughters, Orphe and Lyco, were turned into stones for having too closely watched their sister's intercourse with the lover. Diana, from whom the Lacedæmonians learnt this story, was on that account, as well perhaps as the excellence of the fruit of the tree, therefore worshipped by them under the name of Diana Caryatis. (*Servius*, note on 8th Ecl. of Virgil, edit. Burman.) Another account, however, not at all affecting the hypothesis, is given of the name of Diana Caryatis in one of the old commentators of Statius (*Barthius*, lib. iv. v. 225.). It is as follows. Some virgins threatened with danger whilst celebrating the rites of the goddess, took refuge under the branches of a nut tree (*κάρφα*), in honour and perpetuation whereof they raised a temple to Diana Caryatis. If this, however, be an allusion to the famous interposition of Aristomenes in protecting some Spartan virgins taken by his soldiers, it is not quite borne out by the words of Diodorus. Salmasius (*Exercit. Pliniana*, f. 603. et seq.) says, that Diana was worshipped at Caryæ, near Sparta, under the name of Diana Caryatis; and that at her temple and statue the Lacedæmonian virgins had an anniversary festival, with dancing, according to the custom of the country.

168. But to return more closely to the subject, we will give the words of Pausanias (*Laco-*

nice) on the temple to the goddess at Carya. "The third turning to the right leads to Carya, and the sanctuary of Diana; for the neighbourhood of Carya is sacred to that goddess and her nymphs. The statue of Diana Caryatis is in the open air; and in this place the Lacedæmonian virgins celebrate an anniversary festival with the old custom of the dance." Kuhnus on the passage in question, after reference to Hesychius, says, "Caryatides etiam dicuntur Lacænæ saltantes, sinistrâ ansatæ, uti solebant Caryatides puellæ in honorem Dianæ."

169. From the circumstances above mentioned, we think it may be fairly concluded that the statues called Caryatides were originally applied to or used about the temples of Diana; and that instead of representing captives or persons in a state of ignominy, they were in fact representations of the virgins engaged in the worship of that goddess. It is probable that after their first introduction other figures, in buildings appropriated to other divinities, were gradually employed; as in the Pandroseum (attached to the temple of Minerva Polias),

Fig. 104.

Fig. 105.

for instance, where they may be representations of the virgins called Canephoræ, who assisted in the Panathenæic procession. Fig. 104. is a representation of one of those used in the Pandroseum (see also fig. 102.); and fig. 105. is from the Townley collection, now in the British Museum. Piranesi conjectured that this last, with others, supported the entablature of an ancient Roman building restored by him from some fragments found near the spot where they were discovered, which is rather more than a mile beyond the Capo di Bove, near Rome. Four of the statues were found; and on one of the three, purchased by Cardinal Albani, the following inscription was found: — ΚΡΙΤΩΝ ΚΑΙ ΝΙΚΟΛΑΟΣ ΕΠΙΟΙΟΤΝ; showing that it was the work of Greek artists.

170. The republican spirit of Greece tended to repress all appearance of luxury in their private dwellings. The people seem to have thrown all their power into the splendour and magnificence of their temples; and it was not till a late period that their houses received much attention. Except in the open courts of them, it is difficult to conceive any application of the orders. It is certain that they frequently consisted of more than one story; but beyond this all is conjecture. In the time of Demosthenes (*Orat. adv. Aristocratem*) the private houses had begun to be increased in extent; and the description of them by Vitruvius, who knew Athens well, proves that they were then erected on an extent implying vast luxury.

171. Within the last few years discoveries have been made at Athens, which would lead us to the belief that it was the practice of the Greeks to paint in party colours every portion of their temples, and that in violently contrasted colours. This has received the name of *polychrome architecture*. It is rather strange that no ancient writer has spoken of the practice, and the only way to account for the omission is by supposing it to have been so common that no one thought of mentioning it. From the information of M. Schaubert, the government architect at Athens, it appears that every part of the surface of the Parthenon had a coating of paint. That the coffers of the ceiling were painted, and its frieze ornamented with a fret in colours, was, he observes, known; but the whole building, he continues, as well as other temples, was thickly painted, in the metopæ, in the pediment, on the drapery of the figures, on the capitals, and on all the mouldings. So that, as he says with great simplicity, with its mouldings and carvings variously coloured, the simple Doric temple of Theseus was in effect richer than the most gorgeous example of Corinthian; and it would be worth the trouble to restore with accuracy a polychrome temple. From M. Quast (*Mittheilungen über Alt und Neu Athen*, Berlin, 1834), we learn that the colour was not used in a fluid state merely for the purpose of staining the marble, but in a thick coat, so that the material was completely covered; and that in the temple of Theseus this is more traceable than in any other. Though the colours, that of blue smalt more especially, have left but a grey crust, yet their original tone is still apparent. In this building deep blues and reds are the predominant colours, so as to relieve one another. The corona was deep blue, and the guttæ of a brown red; the foliage of the cymatium was alternately streaked with blue and red, the ground being green, which colour is applied to the small leaves on some of the lesser mouldings. Some of the coffers are coloured of a red inclining to purple, on which the ornament is given; others exhibit a blue ground, with red stars. The architrave of the portico was a bright red; the figures in the frieze were painted in their proper natural colours: traces of the colour show that the walls were green. It was not discovered that in the columns more than the arrises of the flutes were painted, although the echinus was. We do not doubt the accuracy of MM. Semper and Quast; but after all it is possible that all this painting may have been executed at a period much later than that of the buildings themselves.

172. The most ancient theatres of Greece were constructed in a temporary manner; but the little security from accident they afforded to a large concourse of persons soon made the Greeks more cautious for their security, and led to edifices of stone, which, in the end, ex-

ceeded in magnitude all their other buildings. Their form on the plan (see *fig. 106.*) was rather more than a semicircle, and consisted of two parts; the *σκηνη, scena*, and *κοίλον,*

Fig. 106.

PLAN OF A GREEK THEATRE.

*cavea.* The *scena* was at first merely a partition for the actors reaching quite across the stage, dressed with boughs and leaves, but in after times was very differently and more expensively constructed. It had three principal gates, two on the sides and one in the centre; at which last the principal characters entered. The whole scene was divided into several parts, whereof the most remarkable were—the *βροντήιον, brontæum*, under the floor, where were deposited vessels full of stones and other materials for imitating the sound of thunder; the *ἐπισκήνιον, episcenium*, a place on the top of the scene, in which were placed the machines for changing the various figures and prospects; the *παράσκήνιον, parascenium*, which served the actors as a dressing room; the *προσκήνιον, proscenium*, or stage, on which the performers acted; the *ορχήστρα, orchestra*, was the part in which the performers danced and sang, in the middle whereof was the *λόγιον* or *δυμέλη, pulpitum*; the *υποσκήνιον, hyposcenium*, was a partition under the pulpitum, where the music was placed; the *κοίλον, cavea*, was for the reception of the spectators, and consisted of two or three divisions of several seats, each rising above one another, the lowest division being appropriated to persons of rank and magistrates, the middle one to the commonalty, and the upper one to the women. Round the *cavea* porticoes were erected for shelter in rainy weather, the theatre of the Greeks having no roof or covering. The theatre was always dedicated to Bacchus and Venus, the deities of sports and pleasures; to the former, indeed, it is said they owe their origin: hence, the plays acted in them were called *Διονυσιακά, Dionysiaca*, as belonging to *Διονυσος*, or Bacchus. Every citizen shared by right in the public diversion and public debate; the theatre was therefore open to the whole community.

173. The Athenian *αγορά, or fora*, were numerous; but the two most celebrated were the old and new forum. The old forum was in the Ceramicus within the city. The assemblies of the people were held in it, but its principal use was as a market, in which to every trade was assigned a particular portion.

174. The supply of water at Athens was chiefly from wells, aqueducts being scarcely known there before the time of the Romans. Some of these wells were dug at the public expense, others by private persons.

175. The first *gymnasia* are said to have been erected in Lacedæmonia, but were afterwards much improved and extended, and became common throughout Greece. The gymnasium consisted of a number of buildings united in one enclosure, whereto large numbers resorted for different purposes. In it the philosophers, rhetoricians, and professors of all the other sciences, delivered their lectures; in it also the wrestlers and dancers practised and exercised; all which, from its space, they were enabled to do without interfering with one another. The chief parts (*fig. 107.*) following Vitruvius (*lib. v. cap. 11.*), are—A, the *περιστύλιον, peristylum*, which included the *σφαίριστήριον, sphaeristerium*, and *παλαιστρα, palestra*; 1, 2, 3, are the *σῶα, porticus*, with B, *εξέδραι, exhedrae*, where probably the scholars used to meet; 4, 4, is the double portico looking to the south; C, *εφέθειον, ephæbeum*, where the

ephebi or youths exercised, or, as some say, where those that designed to exercise met and agreed what kind of exercise they should contend in, and what should be the victor's reward; *d*, is the coryceum; *z*, the *κομιστήριον*, *conisterium*, where the dust was kept for sprinkling those that had been anointed; *f* is the cold bath (*frigida lavatio*); *g*, the *ἐλαοθεσιον*, *elaothesium*, or place for anointing those that were about to wrestle; *h*, the *frigidarium*, or cold chamber; *i*, passage to the propigneum, or furnace; *l*, the propigneum; *m*, the arched *sudatio*, for sweating; *n*, the *lconicum*; *o*, the hot bath (*calida lavatio*); 5, 7, the two porticoes described as out of the palaestra, of which 7 forms the *xystus*, and 6 a double portico; *a a*, the *margines*, or *semitæ* of the *xystus*, to separate the spectators from the wrestlers; *b b*, the middle part excavated two steps, *c c*, down; *q q*, gardens; *d d*, walks; *e e*, *stationes* for seats; *r r*, *ξύστα*, *xysta*, sometimes called *περίδρομίδες*, for walking or exercises; *s*, the *stadium*, with raised seats round it.

Fig. 107.

PLAN OF A GREEK GYMNASIUM.

It was most probably in much earlier use in Italy. The words *δολος*, *αἶψις*, and *ψαλῖς*, are not used in a sense that signifies an arch until after the reign of the above-named monarch; nor is any description extant from which may be conceived the construction of an arch on scientific principles.

177. From the time of Pericles to that of Alexander, all the arts, and most especially that of architecture, seem to have attained a high state of perfection. Every moral and physical cause had concurred in so advancing them. But perfection, when once reached in the works of man, is only the commencement of their falling away from it. Liberty, the love of country, ambition in every department of life, had made Athens the focus of the arts and sciences: the defeat of the Persians at Marathon and other celebrated victories had brought peace to the whole of the states of Greece. In the space of time preceding the Peloponnesian war, there seems to have been, as it were, an explosion of every species of talent, and it was at this period that they set about rebuilding the temples and other edifices that the Persians had thrown down, of which a wise policy had preserved the ruins, so that the contemplation of desolation and misfortune afforded them an eloquent reminiscence of the peril in which they continually stood. It was indeed only after the flight of the general of Xerxes, and the victory gained by Themistocles, that a general restoration of their monuments and the rebuilding of Athens were set about. These were the true trophies of the battle of Salamis. About 335 years B.C. Alexander became master of Greece. Fired with every species of glory, and jealous of leaving to posterity monuments that should be unworthy of his greatness and fame, or other than proofs of the refinement of his taste, this prince gave a new impulse to genius by the exclusive choice that he made of the most skillful artists, and by the liberal rewards he bestowed upon them. The sacking of Corinth by the Romans in less than two centuries (about 146 B.C.) was the first disaster that the fine arts encountered in Greece; their overthrow there was soon afterwards completed by the country becoming a Roman province. At the former occurrence Polybius

(cited by Strabo) says, that during the plunder the Roman soldiers were seen casting their dice on the celebrated picture of Bacchus by Aristides. Juvenal well describes such a scene (*Satire xi.* 100.):—

Tunc rudis et Graias mirari nescius artes,  
Urbibus eversis, prædædarum in parte reposita  
Magnorum artificum frangebat pocula miles.

The well-known story of the consul Mummius shows either that the higher ranks among the Roman citizens were not very much enlightened on the arts, or that he was a singular blockhead. We have now arrived at the period at which Greece was despoiled and Rome enriched, and must pursue the history of the art among the Romans; incidental to which a short digression will be necessary on Etruscan architecture.

## SECT. XII.

### ETRUSCAN ARCHITECTURE.

178. The inhabitants of Etruria, a country of Italy, now called Tuscany, are supposed to have been a colony from Greece. They certainly may have been a swarm from the original hive (see *Druidical, Celtic*, 13.; and *Cyclopean Architecture*, 32.) that passed through Greece in their way to Italy. The few remains of their buildings still existing show, from their construction, that they are coeval with the walls of Tiryns, Mycenæ (*figs.* 9. and 10.), and other works of a very early age; and it is our own opinion that the wandering from that great central nation, of which we have already so much spoken, was as likely to conduct the Etrurians at once to the spot on which they settled, as to bring them through Greece to the place of their settlement. It is equally our opinion that, so far from the country whereof we now treat having received their arts from the Greeks, it is quite as possible, and even likely, that the Greeks may have received their arts from the Etruscans. The history of Etruria, if we consult the different writers who have mentioned it, is such a mass of contradiction and obscurity, that there is no sure guide for us. It seems to be a moving picture of constant emigration and re-emigration between the inhabitants of Greece and Italy. The only point upon which we can surely rest is, that there were many ancient relations between the two countries, and that in after times the dominion of the Etruscans extended to that part of Italy which, when it became occupied by Grecian colonies, took the name of Magna Græcia. The continual intercourse between the two countries lessens our surprise at the great similarity in their mythology, in their religious tenets, and in their early works of art. We are quite aware that the learned Lanzi was of opinion (*Saggio di Lingua Etrusca*), that the Etruscans were not the most ancient people of Italy. We are not about to dispute that point. He draws his conclusion from language; we draw our own from a comparison of the masonry employed in both nations, from the remains whereof we should, if there be a difference, assign the earliest date to that of Etruria. This, to be sure, leaves open the question whether the country was preoccupied; one which, for our purpose, it is not necessary to settle. We have Winkelman and Guarnacci on our side, who from medals and coins arrived at the belief that among the Etruscans the arts were more advanced at a very early age than among the Greeks; and Dr. Clarke's reasoning tends to prove for them a Phœnician origin.

179. Great solidity of construction is the prominent feature in Etruscan architecture. Their cities were surrounded by walls consisting of enormous blocks of stone, and usually very high. Remains of them are still to be seen at Volterra (*fig.* 108.), Cortona, Fiesole

FIG. 108. WALL AT VOLTERRA.

(*fig.* 109.), &c. "Mœnibus," says Alberti (*De Re Ædific.* lib. vii. c. 2.) "veterum præsertim populi Etruriæ quadratum eundemque vastissimum lapidem probavere." In the walls of Cortona some of the stones are upwards of 22 Roman feet in length, and from 5 to 6 ft. high, and in them neither cramps nor cement appear to have been employed. The walls of Volterra are built after the same gigantic fashion. In the earliest

FIG. 109. WALL AT FIESOLE.

specimens of walling, the blocks of stone were of an irregular polygonal form, and so disposed as that all their sides were in close contact with one another. Of this species is the wall at Cora, near Velletri. The gates were very simple, and built of stones of an oblong square form. The gate of Hercules, at Volterra, is an arch consisting of nineteen stones; a

circumstance which, if its antiquity be allowed to be only of a moderately remote period, would go far to disprove all Lanzi's reasoning, for, as we have noticed in the preceding article, the arch was unknown in Greece till after the time of Alexander. According to Gori (*Museum Etruscum*), vestiges of theatres have been discovered among the ruins of some of their cities. That they were acquainted with the method of conducting theatrical representations is evident from Livy, who mentions an occasion on which comedians were brought from Etruria to Rome, whose inhabitants at the time in question were only accustomed to the games of the circus. The gladiatorial sports, which were afterwards so much the delight of the Romans, were also borrowed from the same people. They constructed their temples peripterally; the pediments of them were decorated with statues, quadrigæ, and bassi rilievi, in terra cotta, many whereof were remaining in the time of Vitruvius and Pliny. Though it is supposed that the Etruscans made use of wood in the entablatures of their temples, it is not to be inferred that at even the earliest period they were unacquainted with the use of stone for their architraves and lintels, as is sufficiently proved in the Piscina of Volterra.

180. The Romans, until the conquest of Greece, borrowed the taste of their architecture from Etruria. Even to the time of Augustus, the species called Tuscan was to be seen by the side of the acclimatised temple of the Greeks.

181. The *atrium* or court, in private houses, seems to have been an invention of the Etruscans. Festus derives its name from its having been first used at Atria, in Etruria: "Dictum Atrium quia id genus edificii primum Atriæ in Etruria sit institutum." We shall, however, allude in the next section to Etruscan architecture as connected with Roman; merely adding here, that in about a year after the death of Alexander the nation fell under the dominion of the Romans.

## SECT. XIII.

## ROMAN ARCHITECTURE.

182. The Romans can scarcely be said to have had an original architecture; they had rather a modification of that of the Greeks. Their first instruction in the art was received from the Etruscans, which was probably not until the time of the Tarquins, when their edifices began to be constructed after fixed principles, and to receive appropriate decoration. In the time of the first Tarquin, who was a native of Etruria, much had been done towards the improvement of Rome. He brought from his native country a taste for that grandeur and solidity which prevailed in the Etruscan works. After many victories he had the honour of a triumph, and applied the wealth he had acquired from the conquered cities to building a circus, for which a situation was chosen in the valley which reached from the Aventine to the Palatine Hill. Under his reign the city was fortified, cleansed, and beautified. The walls were built of hewn stone, and the low grounds about the Forum drained, which prepared the way for the second Tarquin to construct that Cloaca Maxima, which was reckoned among the wonders of the world. The Forum was surrounded with galleries by him; and his reign was further distinguished by the erection of temples, schools for both sexes, and halls for the administration of public justice. This, according to the best chronologies, must have been upwards of 610 years B. C. Servius Tullius enlarged the city, and among his other works continued those of the temple of Jupiter Capitolinus, which had been commenced by his predecessor; but the operations of both were eclipsed by monuments, for which the Romans were indebted to Tarquinius Superbus, the seventh king of Rome. Under him the Circus was completed, and the most effective methods taken to finish the Cloaca Maxima. This work, on which neither labour nor expense was spared to make the work everlasting, is of wrought stone, and its height and breadth are so considerable, that a cart loaded with hay could pass through it. Hills and rocks were cut through for the purpose of passing the filth of the city into the Tiber. Pliny calls the Cloacæ, "operum omnium dictu maximum, suffossis montibus, atque urbe pensili, subterque navigatâ." The temple of Jupiter Capitolinus was not finished till after the expulsion of the kings, 508 B. C.; but under Tarquinius Superbus it was considerably advanced. In the third consulship of Poplicola, the temple was consecrated. As the name, which was changed, imports, this temple stood on the Mons Capitolinus, and embraced, according to Plutarch, four acres of ground. It was twice afterwards destroyed, and twice rebuilt on the same foundations. Vespasian, at a late period, rebuilt it; and upon the destruction of this last by fire, Domitian raised the most splendid of all, in which the gilding alone cost 12,000 talents. It is impossible now to trace the architecture of the Romans through its various steps between the time of the last king, 508 B. C., and the subjugation of Greece by that people in the year 145 B. C., a period of 363 years. The

disputes in which they were continually engaged left them little leisure for the arts of peace; yet the few monuments with which we are acquainted show a power and skill that mark them as an extraordinary race. Thus in the year 397 B. C., on the occasion of the siege of Veii, the prodigy, as it was supposed, of the lake of Alba overflowing, when there was little water in the neighbouring rivers, springs, and marshes, induced the authorities to make an *emissarium*, or outlet for the superfluous water, which subsists to this day. The water of the lake Albano, which runs along Castel Gondolfo, still passes through it. A few years after this event an opportunity was afforded, which, with more care on the part of the authorities, might have considerably improved it, after its demolition by Brennus. This event occurred 389 B. C., and was nearly the occasion of the population being removed to Veii altogether, a place which offered them a spot fortified by art and nature, good houses ready built, a wholesome air, and a fruitful territory. The eloquence, however, of Camillus prevailed over their despondency. Livy (b. vi.) observes, that in the rebuilding, the state furnished tiles, and the people were allowed to take stone and other materials wherever they could find them, giving security to finish their houses within the year. But the haste with which they went to work caused many encroachments on each other's soil. Every one raised his house where he found a vacant space; so that in many cases they built over the common sewers, which before ran under the streets. So little taste for regularity and beauty was observed, that the city, when rebuilt, was even less regular than in the time of Romulus; and though in the time of Augustus, when Rome had become the capital of the world, the temples, palaces, and private houses were more magnificent than before, yet these decorations could not rectify the fault of the plan. Though perhaps not strictly within our own province, we may here mention the temple built in honour of Juno Moneta, in consequence of a vow of L. Furius Camillus when before the Volsci. This was one of the temples on the Capitoline hill. The epithet above mentioned was given to the queen of the gods, a short time before the taking of Rome by the Gauls. It was pretended that from the temple of Juno a voice had proceeded, accompanied with an earthquake, and that the voice had admonished the Romans to avert the evils that threatened them by sacrificing a sow with pig. She was hence called *Moneta* (from *monere*). The temple of Juno Moneta becoming afterwards a public mint, the medals stamped in it for the current coin took the name of *Moneta* (money). This temple was erected about 345 years B. C., on the spot where the house of Marcus Manlius had stood.

183. In the time that Appius Claudius was censor, about 309 B. C., the earliest paved road was made by the Romans. It was first carried to Capua, and afterwards continued to Brundisium, a length altogether of 350 miles. Statius calls it *regina viarum*. Paved with the hardest stone, it remains entire to the present day. Its breadth is about 14 ft.; the stones of which it is composed vary in size, but so admirably was it put together that they are like one stone. Its bed is on two strata; the first of rough stones cemented with mortar, and the second of gravel, the thickness altogether being about 3 ft. To the same Appius Claudius belongs the honour of having raised the first aqueduct. The water with which it supplied the city was collected from the neighbourhood of Frascati, about 100 ft. above the level of Rome. The Romans at this time were fast advancing in the arts and sciences; for in about nineteen years afterwards we find Papirius, after his victory over the Samnites, built a temple to Quirinus out of a portion of its spoils. Upon this temple was fixed (*Pliny*, b. vii. c. 60.) the first sun-dial that Rome ever saw. For a long while the Romans marked only the rising and setting of the sun; they afterwards observed, but in a rude clumsy manner, the hour of noon. When the sun's rays appeared between the rostra and the house appointed for the reception of the ambassadors, a herald of one of the consuls proclaimed with a loud voice that it was mid-day. With the aid of the dial they now marked the hours of the day, as they soon after did those of the night by the aid of the clepsydra or water-clock. The materials for carrying on the investigation are so scanty, and moreover, as in the case of Grecian architecture, without examples whereon we can reason, that we will not detain the reader with further speculations, but at once proceed to that period (145 B. C.) when Greece was reduced to a Roman province. Art, in the strict application of that word, was not properly understood by the victorious Romans; and a barrenness appears to have clung about that whereof we treat, even with all the advantages that Rome possessed. It may be supposed that the impulse given to the arts would have been immediate; but, like the waves generated by the ocean storm, a succession of them was necessary before the billows would approach the coast. Perhaps, though it be only conjectural, the first effect was visible in the temple reared to Minerva at Rome, out of the spoils of the Mithridatic war, by Pompey the Great, about sixty years B. C., after a triumph unparalleled perhaps in the history of the world; after the conclusion of a war of thirty years' duration, in which upwards of two millions of his fellow-creatures had been slain and vanquished; after 846 ships had been sunk or taken, and 1538 towns and fortresses had been reduced to the power of the empire, and all the countries between the lake Mæotis and the Red Sea had been subdued. It is to be regretted that no remains of this temple exist. The inscription (*Plin.* lib. vii. c. 26.) was as follows:—

CN. POMPEIUS. CN. F. MAGNUS. IMP.  
 BELLO. XXX. ANNORUM. CONFECTO.  
 FUSIS. FUGATIS. OCCISIS. IN. DEDITIONEM. ACCEPTIS.  
 HOMINUM. CENTIES. VICIES. SEMEL. CENTENIS.  
 LXXXIII. M.  
 DEPRESSIS. AUT. CAPT. NAVIBUS. DCCCXLVI  
 OPFIDIS. CASTELLIS. MDXXXVIII  
 IN. FIDEM. RECEPTIS.  
 TERRIS. A. MAEOTI. LACU. AD. RUBRUM. MARE  
 SUBACTIS.  
 VOTUM. MERITO. MINERVÆ.

184. The villas of the Romans at this period were of considerable extent; the statues of Greece had been acquired for their decoration, and every luxury in the way of decoration that the age could afford had been poured into them from the plentiful supply that Greek art afforded. To such an extreme was carried the determination to possess every thing that talent could supply, that we find Cicero was in the habit of employing two architects, Chrysippus and Cluavius (*ad Atticum*, lib. iii. epist. 29. and lib. xii. epist. 18.); the first certainly, the last probably a Greek. Their extent would scarcely be credited but for the corroboration we have of it in some of their ruins.

185. Until the time of Pompey no permanent theatre existed in Rome: the ancient discipline requiring that the theatre should continue no longer than the shows lasted. The most splendid temporary theatre was that of M. Æmilius Scaurus, who, when ædile, erected one capable of containing 80,000 persons, which was decorated, from all accounts, with singular magnificence and at an amazing cost. History (*Plin.* xxxvi. 15.) records an extraordinary instance of mechanical skill, in the theatre erected by Curio, one of Cæsar's partisans, at the funeral exhibition in honour of his father. Two large theatres of timber were constructed back to back, and on one side so connected with hinges and machinery for the purpose that when the theatrical exhibitions had closed they were wheeled or slung round so as to form an amphitheatre, wherein, in the afternoon, shows of gladiators were given. Returning, however, to the theatre erected by Pompey, which, to avoid the animadversion of the censors, he dedicated as a temple to Venus: the plan (*Pliny*, vii. 3.) was taken from that at Mitylene, but so enlarged as to be capable of containing 40,000 persons. Round it was a portico for shelter in case of bad weather: a curia or senate house was attached to it with a basilica or hall for the administration of justice. The statues of male and female persons celebrated for their lives and characters were selected and placed in it by Atticus, for his attention to which Cicero (*Epist. ad Attic.* iv. 9.) was commissioned by Pompey to convey his thanks. The temple of Venus, which was attached to avoid the breach of the laws committed, was so contrived that the seats of the theatre served as steps to the temple; a contrivance which also served to escape the reproach of encountering so vast an expense for mere luxury, for the temple was so placed that those who visited the theatre might seem at the same time to come for the purpose of worshipping the goddess. At the solemnity of its dedication the people were entertained with the most magnificent shows that had ever been exhibited in Rome. We cannot prolong the account of this edifice by detailing them,—indeed that would be foreign to our purpose; but we may add, that such a building presents to us a genuine idea of the vast grandeur and wealth of those principal subjects of Rome, who from their own private revenues could rear such magnificent buildings, and provide for the entertainment of the people shows to which all the quarters of the globe contributed, and which no monarch now on earth could afford to exhibit. This theatre was finished about 54 a.c.

186. In the year 45 b.c. Rome witnessed a triumph not less extraordinary than that we have just recorded,—that of Julius Cæsar on his return from Utica. From the commencement of the civil war that had raged he had found no leisure for celebrating the triumphs which induced the people to create him dictator for ten years, and to place his statue in the Capitol opposite to that of Jupiter, with the globe of the earth under his feet, and the inscription "To Cæsar the Demi-God." We need scarcely remind our readers that his first triumph was over the Gauls; that this was followed by that over Ptolemy and Egypt; the third over Pharnaces and Pontus; and the fourth over Juba. The triumph recorded these appropriately; but we leave that—merely observing, by the way, that the fruit of his victories amounted to 65,000 talents and 2822 crowns of gold, weighing together 20,414 Roman pounds,—to state that on this occasion the Circus was enlarged, a lake sunk for the exhibition of Egyptian and Tyrian galleys, and that in the same year he dedicated a temple to Venus Genetrix, and opened his new forum. Warriors are not often inclined to call in the aid of the arts, except for commemorating their own actions. Not so with Cæsar. In the year 44 a.c., after his triumph over the sons of Pompey, we once more find him engaged in the arts of peace. A temple to Clemency was erected by him, in which his statue was placed near to that of the goddess, and joining hands with her. In the next year he laid

the foundations of what at the time were considered two magnificent edifices for the ornament of the city: a temple to Venus, which for grandeur it is supposed would have surpassed every example of that kind in the world; and a theatre of very gigantic dimensions, —both which were afterwards completed by Augustus. But the projects he conceived were only equalled by those of Alexander. He began the rebuilding and repair of many towns in Italy; the drainage of the Pontine marshes, the malaria of which is the curse of Rome to the present day; the formation of a new bed for the Tiber from Rome to the sea, for the purpose of improving the navigation of that river; the formation of a port at Ostia for the reception of first-rate ships; a causeway over the Apennines from the Adriatic to Rome; the rebuilding of Corinth and Carthage, whither colonies had been sent by him, a scheme afterwards perfected by Augustus; a canal through the Isthmus of Corinth to avoid the navigation round the Peloponnesus; and lastly, the formation of an exact geographical map of the Roman empire, with the roads marked thereon, and the distances of the towns from each other. Such was Cæsar, whom to eulogise would be impertinent.

187. Augustus deprived the Romans of their liberty, and in return for the deprivation consoled them with all the gratification the arts could supply. The victorious Romans had known little of the arts in their highest state of refinement, and the degraded Greeks were constrained to neglect them. They were in a state of barrenness during a portion of the last age of the Roman republic; nor did they exhibit any signs of fruitfulness until Cæsar had established the empire on the ruins of the expiring republic, and his successor, giving peace to the universe, closed the temple of Janus, and opened that of the arts. By him skilful artists, pupils of the great masters, were invited from Greece, where, though languishing, they were yet silently working without fame or encouragement. Some who had been led into slavery, like Rachel of old, carried their gods with them — the gods of the arts. Encouraged by the rising taste of their masters, they now began to develop the powers they possessed, and their productions became necessary to the gratification of the people. Thus it was that our art, among the others, born and reared in Greece, made Italy its adopted country, and there shone with undiminished splendour, though perhaps less happy and less durable. Though the exotic might have lost some beauties in the soil to which it was transplanted, the stock possessed such extraordinary vigour that grafts from it still continue to be propagated in every quarter of the globe.

188. The Greek architects who settled in Italy executed works of surprising beauty: they raised up pupils, and founded a school. It must be conceded that it was more an imitative than an original school, wherein it was necessary to engraft Roman taste which was modified by different habits and climate, on Greek art. And here we cannot refrain from an observation or two upon the practice in these days of comparing Greek and Roman architecture. Each was suitable to the nation that used it; the forms of Greek columns, their intercolumniations, the inclination of the pediment, were necessarily changed in a country lying between four and five degrees further north from the equator. But the superficial writers, whose knowledge occasionally appears to instruct the world, never take these matters into their consideration; and we regret, indeed, to admit that in this country the philosophy of the art is little understood by the public, from the professors being generally too much engaged in its practice to afford them leisure for diffusing the knowledge they possess.

189. The Romans were trained to arms from their cradle; and that they were very averse to the cultivation of the arts by their youth, the passage in the *Æneid* (b. vi. v. 847.), which has been so often quoted, is a sufficient proof: —

Excedunt alii spirantia mollius æra  
Credo equidem, vivos ducent e marmore vultus.  
\* \* \* \* \*  
Tu regere imperio populos, Romane, memento;  
Hæ tibi erunt artes.

190. They were at all times anxious to subjugate for their own purposes those nations that successfully cultivated the arts; a motive which, joined to the desire of aggrandisement, induced them at a very early period to carry their arms against the Etruscans, who were in a far higher state of cultivation than themselves. This was also one motive to their conduct in Sicily and Asia Minor; whence, as well as from Greece, they drew supplies of artists for Rome, instead of employing their own citizens. Though in Rome architecture lost in simplicity, it gained in magnificence. It there took deeper root than the other arts, from its affording, by the dimensions of its monuments, more splendour to the character of so dominating a nation. Its forms are more susceptible of real grandeur than those of the other arts, which are put in juxtaposition with nature herself; and hence they were more in keeping with the politics of the people. The patronage of the fine arts by Augustus has never before or since been equalled. They followed his good fortune, they dwelt in the palace, and sat on the throne with him. His boast was not a vain one, when he asserted that he found his capital built of brick and left it of marble. By him was reared in the capital in question the temple and forum of Mars the Avenger; the temple of Jupiter

Tonans, on the Capitol; that of Apollo Palatine, with public libraries; the portico and basilica of Caius and Lucius; the porticoes of Livia and Octavia; and the theatre of Marcellus. "The example," says Gibbon, "of the sovereign was imitated by his ministers and generals; and his friend Agrippa left behind him the immortal monument of the Pantheon."

191. Under Tiberius and Caligula architecture seems to have been in a state of languor, nor do we know of any thing in the reign of Claudius the fifth Cæsar, save the completion of one of the finest aqueducts of Rome, that of *Aqua Claudia*, whose length is 46 m., in more than ten whereof the water passes over arches raised more than 100 ft. from the surface of the ground. Nero's reign, though his taste bordered more on show than intrinsic beauty, was on the whole favourable to architecture. Much could not be expected of a man who covered with gilding a statue of Alexander, and decapitated fine statues for the purpose of substituting his own head for that of the original. The colossal statues of himself which he caused to be sculptured indicate a mind prone to vice and excess. The same taste for exaggeration was carried into his buildings. His prodigality in every way was inexhaustible; he seems rather to have left monuments of expenditure than of taste. A palace, which from its extraordinary richness has been called the *Domus Aurea*, was erected for him by his architects Severus and Celer, than which nothing could be more brilliant nor gorgeous; beyond it no pomp of decoration could be conceived. In the midst of so much wealth the only object of contempt was its possessor. The reader may form some notion of it when told (*Plin. lib. xxxvi.*) that in finishing a part of it Otho laid out a sum equivalent to near 404,000*l.* sterling.

192. Galba, Otho, and Vitellius can scarcely be said to have reigned. It was reserved for Vespasian and his son Titus, the tenth and eleventh Cæsars, to astonish the city, and indeed the world, by such masses of building in amphitheatres and baths as we may predict it will never again see reared. The Coliseum (*fig. 110.*), so named, according to some,

from its gigantic dimensions, but according to others, with more probability, from its proximity to a colossal statue of Nero, was commenced by the father, and finished by the son. According to Justus Lipsius, the seats would hold 87,000 persons; to this number Fontana adds 10,000, which the upper porticoes would contain, and 12,000 more in other parts; making a total of 109,000 spectators who could view at their ease the sports and combats in the arena. We do not think there

Fig. 110.

THE COLISEUM.

is much, if any, exaggeration in Fontana's statement, seeing that the building covers nearly six English acres of ground. The reader will from the above description identify the structure mentioned by Martial:—

Omnis Cæsareo cedat labor amphitheatro,  
Unum pro cunctis fama loquatur opus.

"Biennio post ac menses novem amphitheatri perfecto opere," is the expression of Victor in respect to the time employed in its construction. Though the monument itself be astonishing, still more so is it that such a mass should have taken only two years and nine months in building, even with all the means that the emperors had under their power. We shall reserve a more particular description of it for a subsequent page. In spite of the ravages of time, and the hands, ancient and modern, which have despoiled it for its materials, enough still remains completely to exhibit the original plan, and to enable the spectator to form a perfect idea of the immense mass. The Baths of Titus were another of the wonders of the age. The remains of them are not so perfect as others, but they are still majestic. Besides the edifices erected by Vespasian and his son, they made it a part of their duty to take measures for the preservation of those which existed, and were in need of repair and restoration.

193. The last Cæsar, Domitian, was of a disposition too wicked to be of service to his country: his reign was, fortunately for it, but short. In the year 98, on the death of Nerva, Trajan became master of the empire. He had served against the Jews under Vespasian and Titus, and probably acquired from them and their example a great taste for architecture, in which he shed a lustre upon the country as great as his splendid victories over the Persians and Dacians gained for it in the field. Of his works, which, as Gibbon says, bear the stamp of his genius, his bridge over the Danube must have been a surprising effort. According to Dio Cassius, this bridge was constructed with twenty stone piers in

the river, 150 ft. high and 60 feet wide, bearing arches of 170 ft. span. It was destroyed by Hadrian, his successor : some say out of envy ; but the plea was, that it served the barbarians as an inlet to the empire, as much as it facilitated the passage of its troops to keep them in subjection. His triumphal arches, his column (*fig. 111.*), and forum, and other

*Fig. 111.* COLUMN OF TRAJAN.

works, attest the vigour and beauty of the art under the reign of Trajan. The forum was a quadrangle surrounded by a lofty portico, into which the entrance was through four triumphal arches, and in the centre was the column. Apollodorus was his principal architect, by whom was erected the column above mentioned, which was not only the chef-d'œuvre of the age, but has never been surpassed. It is 110 ft. high, thus marking the height of the hill that had been cut away to receive the forum. "The public monuments with which Hadrian adorned every province of the empire were executed not only by his orders, but under his immediate inspection. He was himself an artist ; and he loved the arts, as they conduced to the glory of the monarch. They were encouraged by the Antonines, as they contributed to the happiness of the people. But if they were the first, they were not the only architects of their dominions. Their example was universally imitated by their principal subjects, who were not afraid of declaring to the world that they had spirit to conceive and wealth to accomplish the noblest undertakings. Scarcely had the proud structure of the Coliseum been dedicated at Rome, before edifices of a smaller scale indeed, but of the same design and materials, were erected for the use

and at the expense of the cities of Capua and Verona. The inscription of the stupendous bridge at Alcantara attests that it was thrown over the Tagus by the contribution of a few Lusitanian communities. When Pliny was entrusted with the government of Bithynia and Pontus, provinces by no means the richest or most considerable of the empire, he found the cities within his jurisdiction striving with each other in every useful and ornamental work that might deserve the curiosity of strangers, or the gratitude of their citizens. It was the duty of the proconsul to supply their deficiencies, to direct their taste, and sometimes to moderate their emulation. The opulent senators of Rome and the provinces esteemed it an honour, and almost an obligation, to adorn the splendour of their age and country ; and the influence of fashion very frequently supplied the want of taste or generosity. Among a crowd of these private benefactors, we select Herodes Atticus, an Athenian citizen, who lived in the age of the Antonines. Whatever might be the motive of his conduct, his magnificence would have been worthy of the greatest kings." We make no apology for so long a quotation from the historian of the *Decline and Fall*, whose expressions are so suitable to our purpose. The family of Herod was highly descended ; but his grandfather had suffered by the hands of justice ; and Julius Atticus, his father, must have died in poverty, but for the discovery of an immense treasure in an old house, the only piece of his patrimony that remained. By the law this would have been the property of the emperor, to whom Julius gave immediate information. Nerva the Just, who was then on the throne, refused to accept it, desiring him to keep it and use it. The cautious Athenian hesitatingly replied, that the treasure was too large for a subject, and that he knew not how to use it. The emperor replied, "*Abuse it then, for 'tis your own.*" He seems really to have followed the monarch's bidding, for he expended the greatest part of it in the service of the public. This man's son, Herodes, had acquired the prefecture of the free cities of Asia, among which the town of Troas being ill supplied with water, he obtained from the munificence of Hadrian a sum equivalent to 100,000*l.* sterling for constructing a new aqueduct. The work on execution amounted to double the estimate ; and on the officers of the revenue complaining, Atticus charged himself with the whole of the additional expense. Some considerable ruins still preserve the fame of his taste and munificence. The Stadium which he erected at Athens was 600 ft. in length, entirely of white marble, and capable of receiing the whole body of the people. To the memory of his wife, Regilla, he dedicated a theatre, in which no wood except cedar was employed. He restored the Odeum to its ancient beauty and magnificence. His boundless liberality was not, however, confined within the city of Athens. "The most splendid ornaments," says Gibbon, "bestowed on the temple of Neptune in the Isthmus, a theatre at Corinth, a stadium at Delphi, a bath at Thermopylæ, and an aqueduct at Canusium in Italy, were insufficient to exhaust his treasures. The people of Epirus, Thessaly, Eubœa, Bœotia, and Peloponnesus experienced his favours, and many inscriptions of the cities of Greece and Asia gratefully style Herodes Atticus their patron and benefactor."

194. Architecture was still practised with success under the Antonines, the successors of Hadrian, among whom Marcus Aurelius was a great patron of the arts. On these history almost instructs us, that the effect of the individual character of the sovereign, and the general and leading circumstances of his reign, are so influential as to enable us from the two last to estimate the prosperity of the first.

195. The rapidity with which after the time of Commodus, that most unworthy son of a worthy father, the emperors succeeded each other, was as unfavourable for the arts as for their country. A little stand was made against their rapid decline, under Septimius Severus, whose triumphal arch still remains as a link in the chain of their decay, and perhaps the first. It is difficult to conceive how in so short a period from the time of Marcus Aurelius, not thirty years, sculpture had so lost ground. In the arch commonly called that of the Goldsmiths, the form and character of good architecture is entirely obliterated. Its profiles are vicious, and its ornaments debased and overcharged.

196. The art was somewhat resuscitated under Alexander Severus, but it was fast following the fate of the empire in the West, and had become almost lifeless under Valerian and his son Gallienus, whose arch is an index to its state in his reign. The number of competitors for the purple, and the incursions of the barbarians, were felt. Aurelian and Probus suspended its total annihilation; but their reigns were unfortunately too short to do it substantial service. The extraordinary structures at Baalbec and Palmyra have been referred, on the authority of a fragment of John of Antioch, surnamed Malala, to the age of Antoninus Pius; but we are inclined to think the style places them a little later than that period. Baalbec, or, as its Syrian meaning imports, the City of Baal, or the Sun, is situate at the north-eastern extremity of the valley of Beaat or Beka, near that place

Fig. 112.

PLAN OF THE TEMPLE AT BAALBEC.

where the two Lebanons unite, about fifty miles to the north-west of Damascus. The first traveller who described it with accuracy was Maundrell, in his Journey from Aleppo

Fig. 113.

CIRCULAR TEMPLE OF BAALBEC.

to Jerusalem, in 1697. It has, however, been since visited, as well as Palmyra, by Messrs. Wood and Dawkins, in 1751, and by M. Volney at a later period. The principal building, the temple, is of a rectangular form, and is seated in the centre of the western extremity of a large quadrangular enclosure, two of whose sides were parallel to those of the temple; and parallel to its front was the third. To this was attached a hexagonal court, serving as a vestibule, in front of which was the grand entrance portico. The length of the quadrangle is about 360 ft. and breadth about 350 ft. (See fig. 112.) The temple, marked A, is, in round numbers, 200 ft. in length, and 100 ft. in breadth; it was dipteral, and had ten columns in front

and nineteen on the sides. That the reader may form some idea of the style, which was to the last degree debased, and would not justify by any utility the extending this ac-

count, we have in *fig. 113.* given the sketch of a circular temple standing near the above. Of Emesa, the other celebrated Coelo-Syrian city, not a vestige remains.

197. Of Tadmor, or Palmyra, denoting both in Syriac as well as Latin a multitude of palm-trees, Solomon was said to have been the original founder. It lies considerably to the east of Baalbec, and upwards of 200 miles from the nearest coast of Syria. Situate between the Roman and Parthian monarchies, it was suffered to observe a humble neutrality until after the victories of Trajan; when, sinking into the bosom of Rome, it flourished more than 150 years in the subordinate though humble rank of a colony. "It was during that peaceful period," observes Gibbon, "if we may judge from a few remaining inscriptions, that the wealthy Palmyrenians constructed those temples, palaces, and porticoes, whose ruins, scattered over an extent of several miles, have deserved the curiosity of our travellers." The ruins of it were discovered by some English travellers towards the end of the 17th century, and were more lately visited by the Messrs. Dawkins and Wood, already mentioned. The power of Zenobia, who wished to shake off the subjection to Rome, was insufficient to withstand the forces of Aurelian, and Palmyra fell into his hands about the year 237. A slight sketch of the ruins (*fig. 114.*) is here

Fig. 114.

RUINS OF PALMYRA.

given. The style of architecture is almost the same as that of Baalbec; and, like that, so vitiated in almost every profile, that we do not think it necessary longer to dwell upon it, although great the extent of its ruins. In the same way, we must pass over those of Djerash, which were visited by Mr. Barry, and of other considerable cities, though some are said to contain examples in a better and purer style.

198. The reign of Dioclesian was extended, and was illustrious from his military exploits. It was also remarkable for the wisdom he displayed in dividing with others the discharge of duties he could not himself perform; as well as, finally, by his abdication and retirement to Spalatro. Architecture was, however, too far sunk for him to raise it; and, though monuments of great grandeur were reared by him in Rome and his native town of Salona, they were degenerated by innovation and a profusion of ornaments which sometimes proved disastrous to those beneath, upon whom they occasionally fell, but the taste for which, among the Romans, had increased by their intercourse with the East. At a period when no sculptor existed in Rome, this monarch raised the celebrated baths there which bear his name. His palace at Spalatro (*fig. 115.*) covered between nine and ten English acres. Its form was quadrangular, flanked with sixteen towers. Two of the sides were 600 ft., and the other 700 ft. in length. It was constructed of stone little inferior to marble. Four streets, intersecting each other at right angles, divided the several parts of the edifice; and the approach to the principal apartment was from a stately entrance, still called the golden gate. By comparing the present remains with the Treatise by Vitruvius, there appears a coincidence in the practice here with the precepts of that author. The building consisted of only one story, and the rooms were lighted from above. Towards the south-west was a portico upwards of 500 ft. long, ornamented with painting and sculpture. We do not think it necessary to follow up further the decay of the arts in the West; it is sufficient to add that the fifth century witnessed the contemporaneous fall of them and of Rome itself.

199. Towards the year 330, the seat of the Roman empire was removed to Constantinople, where the reign of Constantine, though brilliant, was unsuccessful in restoring the arts, upon which religious as well as political causes had begun to act. The establishment of Christianity had less effect on architecture than on her sister arts. The new species of worship could be performed as well in the old as in temples of a new form, or the old columns might be employed in new edifices, in which, indeed, they were eminently serviceable; but statues of the gods were no longer wanted, and the sculptor's art was abandoned. The removal, however, of the government to the Bosphorus retarded the decline of the empire in the East. Byzantium, on whose foundations was placed the city of Constantinople, owed its origin to a colony of Megarians; and little was it to be imagined that its disasters would have closed in so glorious a termination as occurred to it. The ancient city still continued to possess some splendid productions of the schools of Asia Minor, which it almost touched, and in common with which it enjoyed the arts. Constantine profited by the circumstance, restored the monuments, and transported thither the best examples of sculpture.

200. Architecture was called in by the emperor to aid him in affording security, convenience, and pleasure to the inhabitants of the new metropolis. Vast walls surrounded the city; superb porticoes, squares of every kind, aqueducts, baths, theatres, hippodromes, obelisks,

Fig. 115.

PALACE OF DIOCLETIAN AT SPALATO.

triumphal arches, stately and magnificent temples, were provided for the public. Schools of architecture, which none but persons of good birth were allowed to enter, were established, with professors and prizes for the meritorious. With all this care, one might have supposed a plentiful harvest would have been reaped. But, alas! with all the expense, with all the fine marbles that were employed, with the bronze and gold lavished on the construction and decoration of the edifices erected, the art was not re-established on its true principles. Every thing was rich; but, notwithstanding the exaggerated praises of the ignorant writers of the day, every thing was deficient in real beauty. Richness of material will never compensate for want of elegance in form. "The buildings of the new city," observes Gibbon, "were executed by such artificers as the reign of Constantine could afford; but they were decorated by the hands of the most celebrated masters of the age of Pericles and Alexander. To revive the genius of Phidias and Lysippus surpassed, indeed, the power of a Roman emperor; but the immortal productions which they had bequeathed to posterity were exposed without defence to the rapacious vanity of a despot. By his

commands the cities of Greece and Asia were despoiled of their most valuable ornaments. The trophies of memorable wars, the objects of religious veneration, the most finished statues of the gods and heroes, of the sages and poets of ancient times, contributed to the splendid triumph of Constantinople, and gave occasion to the remark of the historian Cedrenus, who observes, with some enthusiasm, that nothing seemed wanting except the souls of the illustrious men whom those admirable monuments were intended to represent."

201. In Rome, the triumphal arch erected in honour of Constantine presents, to this day, an example of the barbarous and tasteless spirit of the age. It is nothing less than an incongruous mixture, in sculpture and architecture, of two periods remote from each other. But, discordant as the styles are, the absurdity of placing on it part of the triumphs of Trajan, whose arch was robbed for the occasion, is still greater. Not only was Trajan's arch despoiled of its bas reliefs, but the columns and capitals, which the architect, from ignorance, scarcely knew how to put together, were stolen for the occasion. We have used the term ignorance of the architect, who, (if the monument were not standing, the fact could scarcely be credited,) with the finest models before his eyes, placed modillions with dentils in the cornice, and has used the same parts in his impost.

202. The partition of the empire at the death of Constantine was injurious as well to the arts as to the empire; and at its reunion by Constantius in 353, he exhibited but little solicitude about their prosperity. On a visit of thirty days to Rome, he presented the city with the obelisk that now stands in front of the Basilica of S. Giovanni Laterano. It had been intended by Constantine for his new city; and, after being brought down the Nile from the Temple of the Sun at Heliopolis, was conveyed to the banks of the Tiber instead of those of the Bosphorus. After being landed about three miles from the city, it was first elevated in the Circus Maximus. This piece of granite is about 115 ft. in length.

203. Julian's name is in bad odour with the Christian world; but he ought, nevertheless, to have justice rendered to him for his administration of the affairs of the empire, his love of freedom, and his patronage of the arts. This emperor, at Constantinople, constructed some porticoes and improved the port; and, even at so remote a spot as Paris, there still remain the ruins of a palace and baths of his construction; a circumstance which should make his memory an object of respect, perhaps veneration, to the inhabitants of that city.

204. Under Valentinian and Valens the arts received little attention, though the former manifested some care for them. Gratian was entitled to a sort of negative praise for leaving the empire of the West to his brother Valentinian II., and that of the East to Theodosius; who, after the death of the former, held the sway of the whole empire, patronising architecture, and erecting many large edifices in Constantinople. After this the empire was lastingly divided. On the death of Theodosius, Arcadius succeeded him in the East, and in the West Honorius, under whom, whilst he was ingloriously enjoying the pleasures and luxuries of his palace at Ravenna, Alaric, king of the Visigoths, entered and pillaged Rome in the year 410. Honorius raised or repaired several of the Basilicæ at Rome; among them that of S. Paolo fuori le Mura; and, in honour of the two emperors, a triumphal arch was erected in the city in 406, but of this no remains are in existence.

205. After this time, for sixty years the empire of the West was in a state of distraction. Nine princes filled the throne during that period, on and off the stage, rather like actors than monarchs. But the extinction of the Roman name could be no longer protracted. In 455, Genseric, king of the Vandals, gave up Rome for pillage to his soldiers for the space of three days, and some years after, his example was followed by Ricimer. In 476, the Roman empire in the West was annihilated.

206. We have thus, in this and the preceding section, shortly traced the history of Roman architecture from its dawn among the Etruscans to the close of the regal power in Rome; and from that period to the time of its culmination under Augustus, an age of great splendour in the art, comparable even with the best days of Athens, if allowance be made for the respective habits of the nations and the climates under which they were placed. From the zenith we have followed it in its setting under Dioclesian, and after that through its crepusculum, which, in 476, was succeeded by total darkness; a darkness, however, not without meteors and coruscations which occasionally enabled us to enlighten the reader in the journey he has undertaken with us. The revolutions, however, of empires, like those of the globe on its axis, bring other dawns: such is the case with the arts, which follow those revolutions; and we shall hereafter have to record another dawn of them, which, like the light of our great luminary, had its day-spring in the east, whence came the architects of Venice and Pisa. But, before we approach that period, it will be necessary to take a cursory glance at those monuments of Rome and other places under its dominion, in which the ruins alone attest the extraordinary power and magnificence of that State, and to examine the details of their construction as respects what simply presents itself to the eye.

207. We now, therefore, proceed to a view, 1. Of the religious buildings of the Romans in quadrangular and circular temples; 2. Of their public buildings in fora, triumphal arches, bridges, aqueducts, theatres, amphitheatres, and baths and circi; 3. Of their private

houses and tombs; confining ourselves to those ruins in the city, and occasionally the provinces, which best illustrate the subject.

208. *Temples.* — 1. The quadrangular Roman temple partook very much of its Greek, or perhaps Etruscan, original; though occasionally, as in the Temple of Peace, there is a very considerable deviation from the type. But the exceptions to the general rule are very few indeed in number. The most beautiful temple of the Corinthian order that perhaps ever existed in the world was the Temple of Jupiter Stator, in the Campo Vaccino (Forum), at Rome. We adopt the name of Jupiter Stator, because by that, though its propriety cannot be now ascertained, it is generally known. Recent excavations have proved that it was an octastyle peripteral temple, with twelve columns in flank, and that the cell occupied eight columns with their intercolumniations in depth. No Greek work could surpass in elegance and beauty the profile of the Corinthian order employed in this edifice. The capital, whether we consider it in design or execution, is unparalleled. At the same time we must admit that it bears every mark of the improvements that had been effected through the medium of Greek artists. Only three columns of it remain; these are 47·65 ft. high, their lower diameter being 4·84; so that, in terms of the diameter, the columns are 9·8 diameters high. The height of the entablature is a small fraction less than one quarter the height of the column. The intercolumniations are, as nearly as possible, 1·5 diameter of the column; whence the size of the temple will be easily determined.

209. Almost at the foot of the Capitol, not far from the Temple of Jupiter Stator, stands the Corinthian Temple of Jupiter Tonans, reputed to have been built by Augustus, of which, as of the last, only three columns remain. This was an hexastyle peripteral (except on the side towards the rock) temple, 115 ft. long and 92 ft. wide, measured from outside to outside of column. The columns are 47·08 ft. high, and their lower diameter is 4·60 ft.; their height, therefore, in terms of the diameter, is very nearly  $10\frac{1}{2}$  diameters. The height of the entablature is 9·77 ft., or not quite one fifth of the height of the column. The intercolumniations are 1·56 diameter. There is a tale in Suetonius, that Augustus had bells suspended round this temple for the purpose of scaring the birds away, which their agitation by the wind effected. The style of this temple is inferior to that last described, yet it is not without beauty, though we must allow the cornice is, as compared with it, deficient in effect.

210. The Temple of Mars Ultor was one of those erected by Augustus. Its profile exhibits a fine and bold example of the Corinthian order. Its whole length was about 116 ft., and its breadth about 73 ft. The cornice of the entablature is wanting. The intercolumniations are about  $1\frac{1}{2}$  diameter.

211. In the Campo Vaccino are the remains of a Corinthian temple, built by M. Aurelius in honour of Antoninus, his predecessor, and Faustina, the daughter of that emperor and wife of M. Aurelius. It was prostyle and hexastyle: the columns are 46·10 ft. high; the entablature 11·03 ft.; diameter of the columns 4·85 ft.; and the intercolumniations, except the centre one, which is wider than the others, are  $1\frac{1}{2}$  diameter of the columns. From the above it follows that the columns are  $9\frac{1}{2}$  diameters high, and the entablature rather less than one fourth the height of the column. The frieze is ornamented with griffins and candelabra in a very good style of art. It is not our intention to describe more than the principal temples, with their parts, but to afford to the reader in this place a general view of the art; we shall therefore merely mention those of the Maison Carrée at Nîmes, and the little edifice at Trevi, which last is erected in a very vitiated style: both are of the Corinthian order, and quadrangular in form.

212. Rome is very poor in examples of Ionic temples, the only two remaining being that of Fortuna Virilis and that of Concord; the first not very pure in its detail, and the latter in the very worst style. The Temple of Fortuna Virilis is of the species called prostyle and tetrastyle; that is, with four columns in front and seven on the sides, whereof the cell occupies four intercolumniations. The height of the columns is 27·35 ft.; the lower diameter of the columns 3·11 ft.; and the height of the entablature 6·78 ft. A peculiarity has been noticed in this example of the different centres of the ornamented members being ranged so as to fall with exactness over the axes of the columns.

213. The Temple of Concord, which is a restoration, as the inscription on it proves, of a former temple that stood on the spot, is most probably of the age of Constantine, and scarcely deserves the notice here taken of it, except as a connecting link in the chain of art. It was hexastyle and peripteral. The eight columns which remain are of red and white granite of different diameters. The bases are Attic, and without plinths, except those of the angular columns. The capitals are inelegant and clumsily sculptured. The mouldings of the architrave have been chiselled away to form a plane surface for containing the inscription. Modillions and dentils are met with in the cornice, and the frieze in the interior was sculptured. The height of the columns is 42·86 ft., and their lower diameter 4·48 ft.; so that they are about  $9\frac{1}{2}$  diameters high. The height of the entablature is 7·2 ft., or about one sixth of the height of the column.

214. The circular temples of Rome and its neighbourhood will next be mentioned. Two of them, that of Vesta at Rome and of the Sybil at Tivoli, of the Corinthian order, are of considerable antiquity. Their cells are cylindrical, and are supposed to have been covered with domes resting on the walls, though that is by no means certain. The Temple of Vesta is raised on three steps, whilst that of the Sybil is raised on a circular basement about five feet high. Both the cellæ are encircled about with a colonnade of the Corinthian order. The capitals of the Temple of the Sybil are extraordinary as pieces of effective art. The leaves of the capital, instead of being *appliquées* to the bell, as in other examples, are in this cut into it, and impart a magical appearance to it. The *tout ensemble* of this temple seems to have been conceived with an eye to its situation, and the order seems calculated only for the spot on which it stands (see *fig. 116.*). The circular Temple

Fig. 116.

TEMPLE OF THE SYBIL.

of Bacchus is of a late date. In its exterior there is nothing to remark, except that it has lost a portico at its entrance which originally belonged to it. It consists of a central circular cell, if such it may be called, surrounded by a circular aisle, the former being separated from the latter by twelve pairs of double columns, coupled in the direction of the radii of the plan; from which columns arches spring, carrying a cylindrical wall 39·36 ft. diameter, covered with a hemispherical dome 65·6 ft. high from the pavement. The aisle or corridor is 14·75 ft. wide, surrounding, as we have said, the double colonnade, from which to the exterior wall is a semicircular vault, whose sofit is 32 ft. high from the pavement. The Temple of Minerva Medica is in a very ruined state; little more than half of it is standing. It was, when perfect, of a cylindrical shape, 110 ft. in diameter; but

Fig. 117.

TEMPLE OF MINERVA MEDICA.

the interior was formed into ten plane vertical faces, each whereof had a semicircular recess open towards the centre of the building. A hemispherical brick dome covered the temple, whose vertex is 113 ft. from the pavement.

A semicircular wing, covered by a hemispherically formed vault, stood on each side of the building, but they are now in ruins.

*Fig. 117.* shows the ruin as it was in 1816, from a memorandum we then made. A rectangular vestibule with four Corinthian columns formed the

entrance, and was surmounted by a pediment roof. The temple now stands in a private garden.

215. We have reserved for the last example of a circular temple the celebrated Pantheon, supposed to have formed at one time a portion of the baths of Agrippa; but whether with truth we must decline investigating, as unconnected with our present purpose. Our own belief is, that the body of the temple was erected in the time of the republic with simple large niches, as in *figs.* 118. and 119., in the left sides whereof it is shown as originally built,

and on the right sides as now standing, and that the portico was appended by Agrippa about A. D. 14, at which time the columns were added to the niches, and other alterations made, as seen on the right half of the plan and section. The interior is circular, and about 139 ft. diameter, measuring from inside to inside of the columns, which are about 33 ft. high. At a height of 75 ft. from the ground in the interior springs the hemispherical dome, which has five horizontal ranks of caissons or panels, the top of the dome being terminated by what is technically termed an *eye*, or circular opening, about 27 ft. diameter. All that is found in the temple is of the Corinthian order.

(216.) *Fig.* 120. is an elevation of the Pantheon, with the portico of the Parthenon below it, for the purpose of comparing the relative sizes of the porticoes of the two buildings. The portico, it will be seen, is octastyle, and projects 62 ft. from the circumference of the circular part of the edifice. The shafts of the columns are plain, and the portico is surmounted by a pediment similar to that on the wall of the building. The columns are 47·03 ft. high, and their lower diameter 4·79 ft. The of the height of the column. The profile of the order is bold and well conceived, and the execution in a good style. It has been stripped of its ornaments, many whereof were bronze, by the cupidity of the possessors of power at various times. Though the present interior is comparatively modern, we think it right to give the following particulars of the order:—The columns are 34·67 ft. high, the lower diameter being 3·64 ft. The shafts are fluted, and have what are called *cablings* up one third of their height. It will be seen on inspection of the plan that these columns are placed in front of the great niches. We are not aware that the circumstance whereto we are about to advert has been heretofore noticed, and we give the result of our

entablature is 10·22 ft., or nearly, not quite a fifth

calculation in round numbers only, as an approximation to the truth. The rules for lighting apartments will form the subject of a future section. We shall here merely observe, that the contents of the building, measuring round the inner convexity of the columns, and not calculating the niches, is about 1,787,300 cubic feet, and that the area of the eye of the dome is about 32 square ft., from which it follows that 2226 cubic ft. of space in this building are lighted by 1 foot superficial of light. The building is neither gloomy nor

dark ; on the contrary a pleasant light is diffused throughout, and darkness is not found in any corner of it. This is a subject well worthy of consideration, and one which we propose hereafter to turn to practical account.

Fig. 120.

ELEVATION OF PANTHEON.

Fig. 120.

PORTICO OF PANTHEON.

217. The Temple of Peace has been reserved by us to close the notices of the Roman temples, because of its deviation from the general form of other Greek and Roman temples, which in the quadrangular species are so formed on one general plan that *ab uno disce omnes* is the expression applicable to them. The *figs.* 121. and 122. represent the plan and section of this building. The former will be seen

Fig. 121.

PLAN OF THE TEMPLE OF PEACE.

to have been rectangular, with a porch extending along the whole breadth of the building in front. This was vaulted, the summit interiorly being 35 ft. high ; and in front were seven semicircular-headed apertures serving as entrances. The length of the temple outside, not including the depth of the porch, was 294 ft. ; depth of the porch 30 ft. ; width of the building 197 ft. The temple was longitudinally divided into three nearly equal parts, whereof the central one was a rectangular *salone* of the whole length of the temple, whose breadth was one third of its length. The roof of this was a vault with three groins, formed by the intersection of semicylindrical vaults at right angles to the pavement was about 116 ft., and

tral one. The height of the vaulting from the appears to have been decorated with sunk panels. We shall not however pursue the

verbal description of this edifice, which will be much better understood by an inspection of the diagrams. We will only add, that although the columns in the interior are entirely gone, and the building is in a sad state of dilapidation, enough has been discovered to prove

Fig. 122.

TEMPLE OF PEACE.

that the restoration here submitted to the reader is not very far from the truth. In many cases the restorations of Palladio, whose works it is the fashion amongst half-instructed architects and still less informed amateurs to decry, are not to be wholly relied on in his capacity of antiquary, and certainly must not be taken for granted; but his restoration of this temple cannot widely differ from the truth. It appears to have been founded by Claudius, and finished by Vespasian after the

conquest of Judea, and seems to have been the depository of the spoils of the temple at Jerusalem. It is uncertain by what accident in the reign of Commodus it was destroyed, but it is conjectured it was restored during his reign. It may not be here altogether out of place to notice that the temple in question seems in some measure to have furnished the hint for the nave of the Italian Duomo with its side aisles. It was but in the addition of the transepts and choir, whose type is indicated even in the basilicæ of the first Christians, that a variation is to be seen. If the cross, however, be not sufficiently apparent in the basilica, it cannot be mistaken in the churches but little later.

218. *Fora*. — 2. The *Forum* of the Romans is described generally in Vitruvius (Book vi. chap. 1.). He directs that it should be a large rectangular area, whose breadth is to be about two thirds of its length. The basilica or court of justice, serving also as an exchange for the merchants, is to be attached to it. The forum in a Roman city was the arena on which business, politics, and pleasure were equally transacted, discussed, and enjoyed. Among the Greeks it was called the *αγορα*, signifying a place in which the citizens were collected. It is here to be observed, that the fora of the Romans were of two sorts: *Fora Civilia* and *Fora Venalia*; the former whereof were designed as well with the object of ornamenting the cities in which they were erected, as for admitting a site for the public courts of justice, and other public buildings; the latter were intended to provide for the necessities and conveniences of the inhabitants, and no doubt bore a resemblance to our markets. The great Forum at Rome was seated between the Palatine and Capitoline hills. Though its boundary cannot now be satisfactorily traced, there seems little doubt that it included the Arch of Septimius Severus, the Temple of Concord, and the Curia or senate house, as well as the building of the Temple of Jupiter Stator, which has been above noticed. Restorations of this have been imagined by more than one artist, and more particularly by an ingenious French artist of the name of Caristie, who has published a thin folio volume on the subject, well deserving the attention of the architectural student; but as we shall presently place before the reader a forum from Pompeii in which less uncertainty exists, we shall not stop here in our enumeration of the other fora of Rome. The Forum of Nerva is said to have been 367 ft. long, and 164 ft. wide. At one end were five arched entrances, and at the other the Temple of Nerva. The Forum of Trajan, built by the emperor whose name it bears, was erected from the foreign spoils taken by him in his wars. The coverings of its edifices were all of brass, and the porticoes and their columns constructed in an exceedingly splendid style of execution. Ammianus Marcellinus (*Hist. lib. xvi.*) describes, with much force, the delight of Constantius on contemplating it when he made his triumphal entry into Rome. The representations make its length 1150 ft., and its mean breadth about 470 ft. In it was the emperor's magnificent column (*fig. 111.*), at one end was the Temple of Trajan, and at the other his Triumphal Arch. This Forum contained the celebrated and splendid Basilica Ulpiana. The other example we shall mention was at Fano, and we mention it because it contained a basilica by Vitruvius himself. He describes the portico of the Temple of Augustus as joining that side of the basilica which was furthest from the centre of the Forum, and a temple of Jupiter as standing at the opposite end. He goes on to describe the Treasury, Prison, and Curia, as placed on the longer sides of the Forum exteriorly to the shops which surrounded the area. The commentators on Vitruvius have been at considerable pains to make out the plan of the basilica of this building from the verbal description of it by the author, — perhaps none of them with greater success than old Daniel Barbaro.

219. But no words convey the description of a place so well as a diagram of the object under consideration; and as there exists at Pompeii a forum so perfect, that all the rules given by our great master are exemplified in it, we here place the plan (*fig. 123.*) of the forum there before the reader, so that he may have a complete notion of the arrangement. Entering from the gate of Herculaneum, the principal street leads to its north-west corner,

whence the access to it is by a flight of steps downwards, through an arch in a brick wall, still partially covered with stucco. It has been conjectured with probability, that the entrances to it were occasionally closed, from the remains of iron gates having been found at some of them. A smaller passage occurs to the right of the arch just mentioned, and a fountain attached to the wall between them. A is supposed to have been a temple of Venus; B, a public granary; C, a temple of Jupiter; D, probably a Senaculum, or council chamber; E, a temple to Mercury; F, a Chalcidicum; G G, curiæ; H, treasury; I, triumphal arch; K, arcostyle portico with ambulatory above.

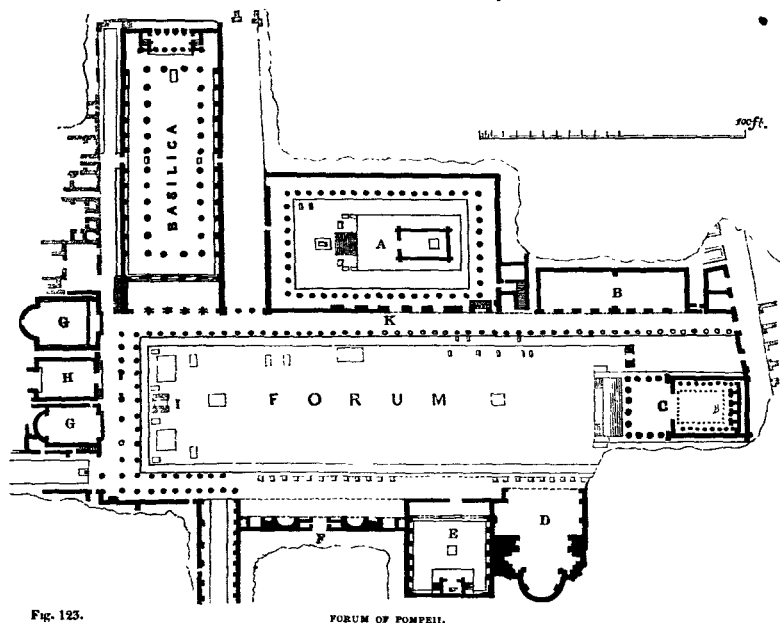

FIG. 123.

FORUM OF POMPEII.

220. *Triumphal Arches.*—The Romans were the first people who erected triumphal arches; their earliest examples being extremely simple and plain. A plain arch with a statue of the victor and his trophies on the summit, was for a long period the only method practised. The arch by degrees expanded in after times, the style became enriched, and the whole was at length loaded with a profusion of every sort of ornament. Latterly they were a rectangular mass (see fig. 124. of the arch of Constantine), penetrated by three arches, a central and two smaller side ones. The upper part consisted of a very high attic, frequently covered with inscriptions and bas-reliefs, statues, triumphal cars and ornaments of that kind. The keystones were sometimes decorated with figures of victory. Of the triumphal arches that remain there are three classes:—first, those consisting of a single arch, as the arch of Trajan at Ancona, and Titus at Rome; second, those in which there are two arches, as in the example at Verona; third, those with three arches, whereof the central was the principal one, and those at the sides much smaller, as the arches of Constantine, Septimius Severus, &c. The most ancient of the remaining arches is that of Augustus at Rimini. It was erected on the occasion of his repairing the Flaminian way from that town to Rome. The erection of these triumphal arches afforded the means of gratifying the extraordinary vanity of the people with whom they originated. Many of them are in very bad taste; a remark that applies even to the Arch of Titus, which was erected before the arts had more than begun to droop. The orders applied to them we do not think it necessary to describe in detail, because inapplicable except under precisely similar circumstances.

221. *Bridges.*—There is perhaps no single point in the history of architecture by which the civilisation of a people is so easily recognised as by that of their bridges. Latterly, in this country, the division of science as well as labour has so changed, that it seems almost necessary to refer to other works for knowledge on this subject; but as this is one in which architecture in all its branches must be considered, we shall here, as in the other sections of this work relating to the point in question, treat it in such manner as to give the reader some notion of the subject. The history of the bridges in every nation is connected with local causes, which have great influence on their construction; and though in other respects a nation may in the arts have attained a high pitch of excellence, yet it is possible that in bridge building their progress may be very limited as respects science. The matter

will depend entirely on the nature of the country. In our view of Grecian Architecture this subject has not been even mentioned, and it is nearly certain that Greece boasts no

Fig. 124.

PLAN AND VIEW OF THE ARCH OF CONSTANTINE.

bridge whose date is anterior to its occupation by the Romans. But, independent of its want of acquaintance with the arch, the circumstance may be accounted for by the country not being intersected by any river of magnitude. Those to which one might be inclined to attach the name of river, are rather mountain torrents than sheets of water rolling their streams down to the ocean. A single arch in most cases would be all that was necessary to connect opposite banks, and the rocks themselves would form abutments for the single arch that was to connect them, without danger of failure.

222. In Italy, however, a country watered by many and considerable rivers, the study of the architecture of bridges was indispensable, as well for the accommodation of the cities with which it abounded, as for the service of the constant military expeditions of the restless and craving people who inhabited its surface. From its very earliest foundation, no city in the world would sooner have been placed in the predicament of requiring bridges than Rome herself; besides which, skill was required in their construction over a river like the Tiber, rapid and liable to be swelled by sudden floods. The earliest bridges of the Romans were of timber: such was that which joined the Janiculum to the Mons Aventinus, called the *Pons Sublicius* from the *sublicæ*, stakes (Liv. i. c. 33.), whereof it was composed. It is not here our intention to enumerate the ancient bridges of Rome; but the ruins of those which have come under our observation exhibit skill and science not inferior to the most extraordinary examples which modern art can exhibit: witness the *Pons Narniensis* on the Flaminian way near Narni, about sixty miles from Rome. It was built by Augustus, and at the present day there remains, as though standing to mock modern science, an arch of a span of 150 ft., whose intrados is 100 ft. above the level of the river below. But of the works of this kind executed by the Romans we know of none, either in ancient or modern times, that is comparable with that erected by Trajan over the Danube, whose piers from their foundation were 150 ft. in height, and the span of whose arches was 170 ft., and to the number of twenty. The bridge was 60 ft. in width. This work, whose existence is scarcely credible, putting in the background all that of which in the present day it is our habit to boast, is reputed to have been destroyed by Hadrian, the successor of its founder, under a pretence that if the barbarians became masters of it, it might serve them as well

for making incursions on the empire, as for the empire in repressing those incursions. But other less creditable motives have been attributed to Hadrian for its destruction, one of them the envy he had of the name of its founder. There are still partial remains of an ancient Roman bridge over the Tagus near Alcantara. This consisted of six arches, each 80 ft. span, extending altogether 800 ft. in length, and some of them 200 ft. high above the river. We do not, in closing our brief view of the bridges of the Romans, more than mention the extraordinary temporary bridge which Cæsar threw over the Rhine.

223. *Aqueducts.* — It is obvious that of all the requisites for a city, the supply of wholesome water is only equalled by that of discharging it, which latter we have before seen was well provided for in the Eternal City. The aqueducts by which the Romans supplied their cities with this necessary element, are among the largest and most magnificent of their works. Their ruins alone, without other testimony, supply the means of estimating their extraordinary power, skill, and industry. They are works which sink into nothingness all other remnants of antiquity, not even excluding the amphitheatres, which we shall soon have to notice, because they were for the comfort, not the pastime, of the people. The earliest aqueduct was that of Appius Claudius, which we have above noticed as constructed in the 442d year of the city. It conveyed the Aqua Appia to Rome, from a distance of between seven and eight miles, by a deep subterranean channel upwards of eleven miles in length. We shall here digress for a moment, by observing that upon the discovery of good water at a distance from the city at a much higher level than the service therein indicated, it was the practice to supply by means of a channel raised at any height as the case needed, through a stone-formed trough raised on the tops of arches as the course of it required over valleys, and otherwise became necessary from the nature of the face of the country, such a quantity as the source would afford. Hence the arcades raised to carry this simple trough of supply were often of stupendous height, and their length was no less surprising. In the present day, the power of steam has afforded other means of supplying a great city with water; but we much question whether the supply afforded by all the concealed pipes of this vast metropolis can compete in refreshment and general utility to its inhabitants with those at the present day poured into Rome, without becoming a burthen to the respective inhabitants, and this principally from the means which their predecessors provided.

224. The aqueduct of Quintus Martius, erected 312 years before Christ, is among the most extraordinary of the Roman aqueducts. Commencing at a spring thirty-three miles distant from Rome, it made a circuit of three miles, and then, after being conveyed through a vault or tunnel of 16 ft. in diameter, continued for thirty-eight miles along a series of arcades 70 ft. in height. It was formed with three distinct channels, one above the other, conveying the water from three different sources. In the upper one was the Aqua Julia, in the next the Aqua Tepula, and in the lowest the Aqua Martia. The Aqua Virginia was constructed by Agrippa, and in its course passed through a tunnel 800 paces in length. The Aqua Claudia, begun by Nero, and finished by Claudius, of which *fig. 125.*

Fig. 125.

AQUA CLAUDIA.

shows several arches, conveyed water to Rome from a distance of thirty-eight miles; thirty miles of this length was subterranean, and seven miles on arcades, and it still affords a supply of water to the city. The Anio was conveyed to Rome by two different channels: the first was carried over a length of forty-three miles, and the latter of sixty-three, whereof six miles and a half formed a continued series of arches, many of them upwards of 100 ft. in height above the ground on which they stood. At the beginning of the reign of Nerva, there were nine great aqueducts at Rome. That emperor, under the superintendence of Julius Frontinus, constructed five others, and at a later period there were as many as twenty. According to Frontinus (*de Aquæductibus*) the nine earlier aqueducts supplied 14,018 quinaria daily, which are equal to 27,743,100 cubic ft.; and it has been computed that when all the aqueducts were in delivery, the surprising quantity of 50,000,000 of cubic ft. of water was afforded to the inhabitants of Rome, so that, reckoning the population at one million, which it probably never exceeded, 50 cubic ft. of water were allowed for the consumption of each inhabitant. More magnificent Roman aqueducts are, however, to be found in the provinces than those that supplied the city. That of Metz, whereof many of the arcades remain, is one of the most remarkable; extending across the Moselle, a river of considerable breadth where it crosses it, it conveyed the water of the Gorse to the city of Metz. From the reservoir in which the water was received, it was conducted through subterranean channels of hewn stone, so spacious that in them a man might stand upright. The arches appear to have been about fifty in number, and about 50 ft. in height. Those in the middle of the river have been swept away by the ice, those at the extremities remaining entire. In a still more perfect state than that at Metz is the aqueduct of Segovia.

of which one hundred and fifty of the arches remain, all formed of large blocks unconnected by cement, in two ranks of arcades one above the other.

225. It has been conjectured that the causes for not carrying these aqueducts in straight lines were first to avoid excessive height, where low grounds were crossed, and, secondly, to diminish the velocity of the water, so that it might not be delivered to the city in a turbid state. Along the line of an aqueduct, according to Montfauçon, at certain intervals, reservoirs called *Castella* were formed, in which the water might deposit its silt; these were round towers of masonry raised of course as high as the aqueduct itself, and sometimes highly ornamented. The same author observes that below the general bed of the channel, pits were sunk for the reception and deposit of the earthy particles which the water contained. Vitruvius directs the channels to be covered over to protect the water from the sun's rays, and (lib. viii. chap. 7.) he moreover directs that when water-pipes are passed across a valley, a *venter* should be formed, which is a subterranean reservoir wherein the water may be collected, and by which its expansion may be diminished, so that the hydrostatical pressure will not burst the joints. He also recommends that open vertical pipes should be raised for the escape of the air which accompanies the water, a practice which the moderns have found it necessary to adopt wherever it is necessary to bend pipes upwards, and thus permit the escape of air, which would impede, and even stop altogether, the movement of the water in them.

226. *Theatres*. — The earliest stone theatre of Rome, as we have before stated (185.), was that of Pompey; but it must be recollected that as there are notices in history of this theatre having been more than once consumed by fire, there can be little doubt that a portion, probably the seats and scenes, were of wood. The second theatre of stone was raised by Julius Caesar, after which Augustus reared one in honour of Marcellus, the son of his sister. The scanty ruins of this last enable one to do little more than trace its elevation, and from their curve to compute its extent. There was no essential difference between the form of the Roman and Greek Theatre, of which latter we have given a diagram in fig. 106. We nevertheless think it right here to present the reader with one of the Roman Theatre fig. 126.), as nearly as it can be made out from the description of Vitruvius. (Book v.

FIG. 126.

PLAN OF THE ROMAN THEATRE.

Chap. 6. "The form of a theatre," according to that author, "is to be adjusted so, that from the centre of the dimension allotted to the base of the perimeter, a circle is to be described, in which are inscribed, at equal distances from each other, four equilateral triangles whose points must touch the circumference of the circle." — "Of these triangles the side of that which is nearest the scene determines the face of it, in that part where it cuts the circumference of the circle. A line drawn parallel to it through the centre

will separate the *pulpitum* of the *proscenium* from the *orchestra*. Thus the *pulpitum* becomes more spacious and convenient than that of the Greeks, because our actors remain chiefly on the *scena*. In the *orchestra* are assigned seats to the senators: the height of its *pulpitum* must not exceed 5 ft., so that the spectators in the *orchestra* may have a clear view of the motions of the actors. The portions between the staircases (*cunei*) of the theatre are to be so divided that the vertices of the triangles, that touch the circumference, may point to the directions of the ascents and steps between the staircases (*cunei*) on the first *præcinctio* or story. Above these the steps are placed alternately and form the upper *cunei* in the middle of those below. The angles thus pointing to staircases will be seven in number, and the remaining five will indicate certain points on the scene. That in the centre, for instance, is the situation for the royal door, those on the right and left the doors of the guests, and those at the extremities the points at which the road diverges. The seats (*gradus*) for the spectators are not to be less than 20 in. in height nor more than 22. Their width is not to be more than 2½ ft. nor less than 2 ft." Besides the theatres named, that of Cornelius Balbus, built by him in honour of Augustus, was on a scale of considerable magnificence.

227. The large theatre at Pompeii, as was frequently the case, was formed upon the slope of a hill, the corridor being the highest part, whence the audience descended to their seats, and staircases were saved. The *gradus* at this theatre were about 1 ft. 3 in. high, and 2 ft. 4 in. wide, and from a part which is divided and numbered off, 1 ft. 3½ in. appear to have been allotted to each spectator. There still remain some of the iron rings, for the reception of the masts from which the *velarium* or awning was suspended.

228. *Amphitheatres*. — The amphitheatre was unknown to the Greeks. At an early period, however, in Rome, human beings were compelled to fight for the amusement of spectators. The taste for such spectacles increased with its indulgence; but it was nevertheless not

until the time of the emperors, that buildings were erected solely for exhibition of gladiatorial shows. The principal amphitheatres, of which remains still exist, are one at Alba, a small city of Latium; another near the Tiber at Otricoli; one of brick near the banks of the Garigliano; one at Puzzuoli, wherein parts of the arcades and caves for wild

Fig. 127.

AMPHITHEATRE AT POLA.

beasts still remain; one at Capua; another at Verona; a very fine one at Pola in Istria (fig. 127.). In France, Arles, Saintes Autun, Nismes, and Nice possessed amphitheatres. In short, wherever the Romans went, they erected those extraordinary monuments of their power and skill. But all that we have enumerated were far surpassed by the Coliseum, which has been already briefly mentioned by us at page 79. The form of this building on the plan is an ellipse, whose transverse exterior axis is 615 ft. and its conjugate 510 ft., covering therefore nearly six English acres of ground. The whole mass is placed on an ascent of six stages, which encircle its whole circumference. In the centre is the *arena*, a name which it received from being strewed with sand, the transverse and conjugate axes whereof are 281 and 176 ft. respectively. Round the arena was a wall on which was the *podium* or fence; and immediately behind this wall all round was a row of cells in which the beasts were placed preparatory to their entrance into the arena. In the rear of the cells was a corridor from which vaults radiated in directions perpendicular or nearly so to the curve of the ellipse, and serving to support the first *manianum* or interior range of seats. In some of these vaults were steps leading to the podium; others were merely passages between the first corridor and the next towards the interior. The second corridor was lighted by apertures cut through its vault to the *præinctio* which separated the first and second horizontal division of the seats. In rear of the second corridor, vaults again radiated, in some whereof were steps leading to the second division of the seats, and in others were galleries which led from the corridor to the double arcade, surrounding the whole edifice. The description will be better comprehended by reference to figs. 128. and 129., in the latter whereof a portion of the exterior side is removed, to exhibit the section.

229. About the whole exterior of the building, there are three orders of columns rising above each other, and one of pilasters crowning the whole. The columns are of equal diameter, and are filled in between with eighty arcades in each story. The arches of these arcades have all archivolt mouldings round them. Four of the arcades in the lower tier were reserved for the admission of distinguished personages, the remainder for the populace; these last were called *vomitoria*, serving both for ingress and egress to and from the places of the spectators, by means of steps under the vaults that supported the seats. The piers which support the arches are 7 ft. 4 in. wide; on each is a half column projecting from the general face of the wall. The opening between the piers is 17 ft. 3½ in. Impost mouldings are placed at the springing of the arches, and encircle the building except where interrupted by the columns and openings. The lower order resembles the Doric, except that the frieze is without triglyphs and the cornice without mutules. Desgodetz makes the height of the columns 27·63 ft., and their lower diameter 2·91 ft. Their diminution is very small. The height of the entablature is 6·64 ft., and the height, therefore, of the whole order above the pavement is 34·27 ft. The second order is Ionic, and stands on a dado 6 ft. high, broken under the columns to receive their projection from the wall. The columns are 25·73 ft. high. The volutes of the capitals are without ornament; the eye being merely marked by a circle. The entablature is 6·64 ft. high, and its subdivisions are like that in the order below. There are neither modillions nor dentils in the cornice. The height of the whole order is 38·37 ft. The third order is Corinthian, standing on a dado 6·39 ft. high. The columns are 25·58 ft. high, the entablature 6·59 ft., and the height of the entire order, including the dado, is 38·57 ft.

The upper story is decorated with a series of Corinthian pilasters on subplinths 2.79 ft. high, placed on a dado of the height of 7 ft. The height of the pilasters, which are not

Fig. 128

PLAN OF COLISEUM.

diminished, is 28 ft., and the height of their entablature is 7.37 ft. The frieze and architrave are broken vertically in each interpilaster over three corbels, on which it is supposed,

Fig. 129.

SECTION AND ELEVATION OF COLISEUM.

running through the back part of the cornice, poles were placed for holding the *velarium*, which was occasionally stretched over the building to protect the spectators from the sun or rain. The whole height of the façade above the steps was 162 ft. The columns project rather more from the walls than their semidiameter; and the faces of the walls are not in the same vertical plane, but recede from it towards the interior of the building. The widths of the piers vary in the different stories, being respectively from the lower part upwards as 8.71, 8.38, and 7.28 ft. Between the pilasters, in the fourth order, are square windows. The *velarium* was attached to the poles round the circumference with a fall towards the interior, so that the rain was delivered into the arena. The following has been supposed as a method of spreading the *velarium*, of which Fontana gives a representation, but no description. A cable being placed round the edge, and following the curve of the podium, strong ropes were attached to it in the direction of the radiating walls on the plan, and passing through pullies in the poles at the top of the building, which were 240 in number, resting on the corbels before mentioned, so that the whole might be raised to the required height. It would follow the inclination of the seats, and the cloth, of whatever fabric or materials it might be, being formed in gores equal on the outer edges to the distance of the masts from each other, might move on the radiating ropes by rings attached to the edges of

each gore, so as to be moved backwards and forwards by persons stationed on the parapet. Marine soldiers were employed for this purpose. The velarium was sometimes of silk, but more usually yellow or brown woollen cloth. Nero once had a purple velarium stretched across the building, representing the heavens with stars of gold on it, and a design embroidered thereon of the Chariot of the Sun.

230. It has been conjectured by some Roman antiquaries that the arena was boarded; and, from the changes that could be made on it in a very short period, the conjecture is highly probable. Domitian covered it with water for the purpose of exhibiting marine shows and naval fights. Sometimes it was changed into the representation of a forest with wild beasts roaming about. These alterations were effected by means of machines called *pegmata*. In particular parts of the building, pipes were provided for the distribution of perfumes, which it was a common practice to sprinkle in showers; but, on particularly great occasions, the perfumes were allowed to flow down the steps or gradus of the amphitheatre.

231. The conjecture relative to the boarded floor of the arena has been corroborated by the discoveries made while the French had possession of Rome. They excavated the arena, and found vaults and passages under its whole area. It is much to be regretted that these inquiries were not carried on, owing to an accumulation of waters, for which no drainage having been provided, they became unwholesome from stagnancy, and it therefore was necessary once more to close it again by obvious means. Great care was bestowed on the drainage of this edifice, which was encircled by a large sewer for the reception of the water of the interior drains, that were all conducted into it. Another drain, 30 inches wide, was carried round under the second corridor, into which are conveyed the water from the perpendicular conduits and that from the third corridor, whose drain is 3 ft. in depth and 17 inches in width. The sides of these drains are lined with tiles. Another drain runs on the outer side of the third corridor, and is of the same size as the last named. Other drains communicate with these towards the arena in various directions.

232. Paoli thinks that amphitheatres were first used by the Etruscans, and by them introduced into Rome; that the people in question first exhibited their games in narrow valleys, and that the spectators were ranged around on the sides of the hills; that when these sports were exhibited in cities, an arena was dug into the level ground, and the earth thrown out was formed into seats; and that when the community became rich enough, or the games came to be held in greater esteem, the amphitheatre was enclosed with a wall, and the seats formed of wood or stone. It certainly appears to us that Paoli's conjecture is reasonable, and that Etruscan buildings or formations were the original type.

233. The amphitheatre at Nismes was capable of containing 17,000 persons: it was 400 ft. long and 320 ft. broad. That at Verona, upon whose age antiquaries are divided in opinion, some maintaining that it was built in the time of Augustus, and others as late as the time of Maximian, Maffei making somewhat of a mean between the two periods, is of an elliptical form, 508 ft. long and 403 ft. broad. It is in much better preservation than the Coliseum. Its exterior wall has three stories of Tuscan pilasters on the face of the wall, the two upper whereof stand on podia. Between these pilasters are arcades of semi-circular-headed apertures. Maffei says, that allowing a foot and a half of room for each person, this edifice would seat 22,000 spectators.

234. *Baths.* — Publius Victor says that the city of Rome contained public and private baths to the amazing number of 850. Some of these we know, from their ruins, were buildings of great extent and magnificence. They were all constructed, we mean the public ones, on plans very similar; and, in order to a description of them, we give in *fig.* 130. a restored plan of the baths of Caracalla, at Rome. Those of Titus and Dioclesian may also be traced; the chief others being those of Agrippa, Nero, and Domitian. The baths of Antoninus Caracalla are thus described by Eustace (vol. i. p. 226.): "Repassing the Aventine Hill, we came to the baths of Antoninus Caracalla, that occupy part of its declivity, and a considerable portion of the plain between it, Mons Cæliolus and Mons Cælius. No monument of ancient architecture is calculated to inspire such an exalted idea of Roman magnificence as the ruins of their thermæ, or baths. Many remain in a greater or less degree of preservation; such as those of Titus, Dioclesian, and Caracalla. To give the untravelled reader some notion of these prodigious piles, I will confine my observations to the latter, as the greatest in extent and as the best preserved; for, though it be entirely stripped of its pillars, statues, and ornaments, both internal and external, yet its walls still stand, and its constituent parts and principal apartments are evidently distinguishable. The length of the thermæ was 1840 ft., its breadth 1476'. At each end were two temples; one to Apollo, and another to Esculapius, as the tutelary deities (*genii tutelares*) of a place sacred to the improvement of the mind and the care of the body. The two other temples were dedicated to the two protecting divinities of the Antonine family, Hercules and Bacchus. In the principal building were, in the first place, a grand circular vestibule, with four halls on each side, for cold, tepid, warm, and steam baths: in the centre was an immense square for exercise, when the weather was unfavourable to it in the

Fig. 130

BATHS OF CARACALLA.

open air; beyond it a great hall, where 1600 marble seats were placed for the convenience of the bathers: at each end of this hall were libraries. This building terminated on both sides in a court surrounded with porticoes, with a spacious odeum for music, and in the middle a spacious basin for swimming. Round this edifice were walks shaded by rows of trees, particularly the plane; and in its front extended a gymnasium for running, wrestling, &c. in fine weather. The whole was bounded by a vast portico, opening into exedrae, or spacious halls, where the poets declaimed and philosophers gave lectures to their auditors. This immense fabric was adorned within and without with pillars, stucco work, paintings, and statues. The stucco and paintings, though faintly indeed, are yet in many places perceptible. Pillars have been dug up, and some still remain amidst the ruins; while the Farnesian bull and the famous Hercules, found in one of these halls, announce the multiplicity and beauty of the statues which adorned the thermæ of Caracalla. The flues and reservoirs of water still remain. The height of the pile was proportioned to its extent, and still appears very considerable, even though the ground be raised at least 12 ft. above its ancient level. It is now changed into gardens and vineyards; its high massive walls form separations, and its limy ruins, spread over the surface, burn the soil and check its natural fertility."

235. Returning to the plan of the baths in question, we have now to explain that the circular apartment, lettered A, was called the solar cell. It was 111 ft. in diameter, and contained the different *labra* of the baths. This solar cell, Spartianus says, could not be equalled by the best architects of that age. The dome was lined with brass, of which material also were the lattices to the windows. B, the *apodyterium*, or undressing room. C, a *xystus*, or apartment for exercise in unfavourable weather. D contained the piscina, or large reservoir for swimming. E, vestibule for spectators and the dresses of the bathers. F, entrance vestibule of the thermæ, having libraries on each side. G G, rooms wherein the *athletæ* prepared for their exercises. H, a court, having a piscina for bathing in the centre. I, *ephebeum*, place of exercise for the youth. K K, the *eleutherium*, or apartment for anointing the bathers with oil. L L, vestibules. M, *laconicum*, an apartment so called, as it is said, from the name of the stove by which it was heated, and from the custom of the *sudatio*, or sweating, having originated in Laconia. N, *caldarium*, or hot water bath, which was most frequented. O, *tepidarium*, or tepid water bath. P, *frigidarium*, or cold water bath. Q, *exedrae* for seats for the use of the philosophers and their scholars. W, rooms for conversation. R R, *exedrae*, or large recesses for the use of the philosophers. Y, *conisterium*, or place where, after anointing, the wrestlers were sprinkled with dust.

236. We have just given the common explanation to the word *laconicum*; but it is right the reader should know that its true meaning is in some doubt. Galiani considers it a great chamber wherein the people underwent sweating. To this Cameron adds, "I for myself hold it certain that the apartment for this purpose has been by some authors improperly termed; the *laconicum* is nothing more than a little cupola which covered an aperture in the pavement of the hot bath, through which the vivid flame of the hypocaustum, or furnace, passed and heated the apartment at pleasure. Without this means," continues that author, "the hot bath would not have had a greater heat than the other chambers, the

temperature of which was milder. I have been induced to form this opinion, not only from the ancient paintings found in the baths of Titus, but also by the authority of Vitruvius, who says that the hot bath (*concamerata sudatio*) had within it, in one of the corners, or rather ends, the laconicum. Now, if the laconicum was in the corner of the hot bath, it is clear that it is not the bath itself, but merely a part of it; and if, as others have thought, it was the hot bath itself, to what purpose served the *concamerata sudatio*?"

237. The baths and thermæ of the Romans, like the gymnasia of the Greeks, were highly ornamented with bassi relievi, statues, and paintings. The basins were of marble, and the beautiful mosaic pavements were only equalled by the decorations of the vaults and cupolas. Nothing more strongly proves the magnificence and luxury of the ancient Romans than the ruins of the baths still to be seen in Rome. Agrippa decorated his baths with encaustic paintings, and covered the walls of the caldarium with slabs of marble, in which small paintings were inserted. All these luxuries were introduced under the emperors; and the mere act of bathing, as described by Seneca in the instance of Scipio Africanus, appears to have been almost lost in the effeminacy of the later practice. The splendour of the places may be judged of by calling to the remembrance of the reader that the celebrated statue of the Laocoon was one of the decorations of the baths of Titus, and that of the Farnese Hercules of the baths of Caracalla.

238. We have, in the section on Aqueducts (224.), stated the extraordinary quantity of water with which the city was supplied by them, and there can be no doubt that the baths caused a very great consumption of that necessary article of life. After the removal of the empire to Constantinople, we hear of no thermæ being erected; and it is probable that at that period many of those in the city fell into decay. The aqueducts by which they were supplied were, moreover, injured by the incursions of invaders, another cause of the destruction of the baths. Remains of Roman baths have been discovered in this country, for descriptions whereof the reader is referred to the *Archæologia*.

239. We shall conclude our observations on the Roman baths by the mention of some curious paintings in the baths of Titus, very similar in their features to those found in places on the walls of Pompeii; we allude to representations of slender twisted columns, broken entablatures, and curvilinear pediments, columns standing on corbels attached to the walls, a profusion of sculpture, with fantastic animal figures and foliage, and many other *extravaganzas*, which found imitators after the restoration of the arts, and, in some cases, with great success.

240. *Circi*.—The circus of the Greeks was nothing more than a plain, or race course; from its length called *Στάδιον* (stadium); as also *Κίρκος*, from its oval figure. With the Romans it became a regular building of great dimensions and magnificence. The *Circus Maximus*, constructed originally in a rude manner by Romulus, and afterwards rebuilt by the elder Tarquin, is, in its external dimensions, computed to have been 2000 ft. long and 550 ft. broad, consisting of two parallel walls in the direction of its length, united at one extremity by a set of apartments, called *carceres*, arranged in the form of the segment of a circle of about 430 ft. radius; and, at the opposite short end, by a semicircular enclosure. The *carceres* contained the chariots ready for starting. The *arena*, or space thus enclosed, contained a long low wall called the *spina*, 1300 ft. in length, running along its longitudinal axis, and commencing at the centre of the semicircular end, having a *meta*, or goal, at each of its extremities. Like those of the theatre and amphitheatre, the seats of the spectators were placed round the arena with a podium in front; between which and the *spina* the races of the chariots were exhibited. The circus of Nero was nearly of the same form, but neither so long nor so broad, being only 1400 ft. in length and 260 in breadth, and its *spina* but 800 ft.

241. The remains of the circus of Caracalla, of which Bianconi has given a very good account, are still sufficiently abundant to trace the plan (*fig. 131.*). It was nearly of the same dimensions as that of Nero. There are in this building some curious examples of lightening the spandrels of the arches over which the seats were constructed, by filling them in with light vessels of pottery; a practice which has been partially adopted in some modern buildings, and is still usefully practised on the Continent. Generally speaking, the circus was a parallelogram, whose external length was from four to five times its breadth. It was surrounded by seats ranged above each other and bounded by an exterior wall, probably pierced with arcades. The *spina* was about two thirds the length of the building, and was ornamented with statues, obelisks, and other ornaments, terminated at each end by the *meta*, which consisted of three obelisks or columns. The *carceres* were closed by gates in front and rear, which were not opened till the signal was given for starting. In the circus of Caracalla, it will be seen that these *carceres* were placed obliquely to the long sides of the edifice, so as to equalise the length of their course from the starting point to the goal. So that it would seem there was as much nicety in a chariot race of old as in a modern horse race.

242. *Private Houses*.—The domestic architecture of the Romans possesses great interest; the general instructions spread over the sixth book of Vitruvius upon their parts and pro-

Fig. 121. PLAN OF CIRCUS OF CARACALLA.

portions have received much illustration from the discoveries at Pompeii; and it is pleasant to find that, following his merely verbal directions, a building might be planned which would correspond as nearly with what we now know was the case, as two houses, even in a modern city, may be expected to resemble one another. In the following observations we have used most abundantly the elegant little work of Mazois (*Le Palais de Scaurus*, 2d ed. 8vo. Paris, 1822), and feel a pleasure in thus acknowledging our obligations to that author; but, before more immediately using his observations on the later habitations of the Romans, we shall premise that until after the war of Pyrrhus, towards the year 280 a.c., the use of tiles as a covering for them appears to have been unknown. Till then thatch or shingles formed the covering of the houses. They consisted of a single story; for, according to Pliny (lib. xxxiv. c. 15.) and Vitruvius (lib. ii. c. 8.), a law was in force forbidding walls of a greater thickness than one foot and a half; whence it is clear they could not have been safely raised higher than a single story with the unbaked bricks then in use. But the space within which the city was confined, with an increasing population, rendered it necessary to provide in height that which could not be obtained in area; so that, in the time of Augustus, the height of a house was limited to 70 ft. (*Aurel. Vict.*; and *Strabo*, lib. v.)

243. The extraordinary fortunes that were realised in Rome towards the last years of the republic, when the refinements of the arts of Greece were introduced into the city, soon led its more favoured citizens to indulge in architectural splendour. Lucius Cassius had decorated his dwelling with columns of foreign marble; but all other private edifices were thrown into shade by that of Scaurus, in which were employed black marble columns of the height of 38 ft. Mamurra lined his apartments with marble; and, indeed, such was the prodigality, for it deserves that term, of the Romans, that Pliny (lib. xvii. c. 50.) tells us of Domitius Ahenobarbus having offered a sum equivalent to 48,500*l.* sterling (*sexagies sesterium*) for the house of Crassus, which was refused. Their villas were equally magnificent. Cicero had two of great splendour—his Formian and Tusculan villas; but these were exceeded in beauty by those of Lucullus and Pollio, the latter near Posilippo, where some remains of it are still to be seen. Though Augustus attempted to stop this extraordinary rage for magnificence, he was unsuccessful; and the examples which were afforded by later emperors were unlikely to restrain the practice where the means existed. In the *Domus Aurea* of Nero, domestic architecture appears, from all accounts, to have reached the utmost degree of splendour and magnificence.

244. In the better class of Roman dwellings, certain apartments were considered indispensable; and these, in different degrees of size and decoration, were always found. There were others which were or were not so found, according to the wealth and fancy of the proprietor. Thus, every private house of any pretension was so planned that one portion was assigned to the reception of strangers, or rather for public resort, and the other for the private use of the family. The public part was destined for the reception of dependants or *clients*, who resorted to the house of their patron for advice and assistance.

The number of these clients was honourable and useful to the patron, as they might, in civil matters, be depended on for their votes. Hence lawyers especially had their houses thronged with them; and it is amusing in the present day to see the term of *client* still kept up among our barristers: for although his state of dependence has lost nothing of its extent, the eminence of the patron is now measured by the quantity and amount of fees his clients enable him to consume. Vitruvius describes the public portion as consisting of the *porticus*, *vestibulum*, *cavædium* or *atrium*, *tablinum*, *alæ*, *fauces*, and some few others, which were not added except at the especial desire of the party for whom the building was to be erected.

Fig. 132. DOOR AND PROTHYRUM, POMPEII.

245. The parts which were sacred to the use of the family were the *peristyle*, the *cubicula* (sleeping apartments), the *triclinium*, the *æci*, the *pinacotheca*, or picture galleries, the *bibliotheca*, or library, baths, *exedra*, *xysti*, and others.

246. In the more extended mansions of the Romans was an area, surrounded on two sides by porticoes and shops, and ornamented with statues, trophies, and the like, and on the third (the fourth being open) was the decorated entrance or portico of the house. But in smaller dwellings this entrance or portico was in a line with the front of the houses in the street; the vestibule or *prothyrum* (fig. 132.) being in the Roman houses merely a passage room, which led from the street to the entrance of the atrium. In this vestibule, or rather by its side, the *ostiarius* or porter was stationed, as in French houses we find a *concierge*. When there were two courts, we are inclined to think that the one nearest the street was called the *atrium*, and the farthest from it the *cavædium*; but in many cases we also think that the atrium served equally as a *cavædium* according to the owner's rank. The explanation of Varro will certainly answer for one as well as the other. It may be that the *cavædium* was a second atrium of larger size.

247. Of the atrium Vitruvius describes five sorts: 1. The *Tuscan*, wherein the protecting roof was a sort of pent-house on the four sides, supported by beams framed at right angles into each other; the space in the centre forming the *compluvium*, and the basin or area in the centre the *impluvium*. 2. The *tetrastyle* atrium (one with four

Fig. 133.

CORINTHIAN ATRIUM.

columns), which was similar to the Tuscan, except that the angles of the beams of the roof or pent-house rested on four columns. 3. The Corinthian atrium (*fig. 133.*), which differed only from the last in its size, and the number of its columns. 4. The *atrium displuviatum* in which the slope of the roofs was towards the body of the building. 5. The *atrium testudinatum*, which was covered with a ceiling, and with nothing more than an aperture therein to afford light. The compluvium was sometimes (*Plin. xix. c. i.*) provided with a sort of awning. The roof of the four sides of the atrium was covered with ornamental tiles, the eaves' faces whereof were terminated between their sloping junctions with carved faces called *antefixa*, similar to those in the roofs of the Grecian temples. The atrium was, moreover, frequently embellished with fountains. It was in the atrium that the splendid columns which we have mentioned, as decorating the house of Scæurus, were placed. The walls were either lined with marble or painted with various devices, and the pavement was decorated with mosaic work or with precious marbles.

248. The *tablinum*, which usually opened towards the atrium, seems to have been a sort of levee room, wherein the master of the mansion received his visitors or clients, lists of whom were therein recorded, and where the *mæstro di camera* announced their names. Some have thought, and we do not say they are wrong, that this apartment contained (which it might also do without affecting the truth of the first supposition) the family archives, statues, pictures, pedigree, and other appurtenances incident to a long line of ancestors.

249. The apartments on the sides right and left of the tablinum were called, as their name signifies, *alæ*. These were also furnished with portraits, statues, and other pieces relative to the family, not omitting inscriptions commemorative of actions worthy their name.

250. Two corridors, one on each side of the atrium, which led to the interior of the house from the atrium, were called *fauces* (jaws).

251. In houses of moderate dimensions, chambers were distributed round the atrium for the reception and lodging of strangers; but in establishments of importance, wherein the proprietor was a person of extended connexions, there was a separate *hospitium* appropriated to that purpose.

252. We have stated that the peristyle was a portion of the private part of the house. It was mostly, if not always, placed beyond the atrium, with which it communicated by means of the tablinum and fauces. Similar in general form and design to the atrium, for it was surrounded by columns (*see fig. 134.*), it was larger than that apartment. The centre was usually provided with a parterre in which shrubs and flowers were distributed, and in its middle a fish pool. This portion of the peristyle was called the *xystus* (*Vitr. lib. vi. c. 10.*). In better houses there was an ante-room called *procæton*, to each of the bed-chambers, of whose arrangement very little is known. The triclinium (*τρεῖς κλινæ*, three beds), or dining-room, was so called from its having three couches round the table on which the dinner was served; the fourth side being left open for the servants (*see fig. 135.*). It was raised two steps from the peristyle, and separated

Fig. 134.

PERISTYLE AT POMPEII.

from the garden by a large window. Winter triclinia were placed towards the west, and those for summer to the east. In large houses there were several triclinia, whose couches would contain a greater or less number of people. The *œci* were large *salons* or halls, of Greek origin, and, like the *atria*, were of more than one species; as for instance the tetrastyle, the Corinthian, and the Egyptian. "There is this difference," observes Vitruvius (*lib. v. cap. 6.*), "between the Corinthian and Egyptian œcus. The former has a single order of columns, standing either on a podium or on the ground, and over it architraves and cornices, either of wood or plaster, and a semicircular ceiling above the cornice. In the Egyptian œcus, over the lower column, is an architrave, from which to the surrounding walls is a boarded and paved floor, so as to form a passage round it in the open air. Then, perpendicularly over the architrave of the lower columns, columns one fourth smaller are placed. Above their architraves and cornices, they are decorated with ceilings, and windows are placed between the upper columns. Thus they have the appearance of basilicæ rather than of Corinthian triclinia." The œcus, called *Cyzicene* by the Greeks, was different to those of Italy. Its aspect was to the north, towards the gar-

Fig. 135. SMALL TRICLINIUM AT POMPEII.

which was paved with mosaic. B B B B, Tuscan atrium, in whose centre is the compluvium or basin (b) for the reception of the water from the roof. One of the proportions

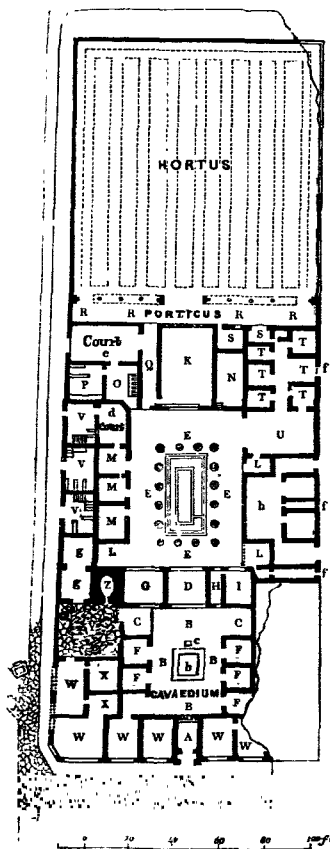

Fig. 136. PLAN OF HOUSE OF PANSIA.

assigned to the atrium by Vitruvius is, that the length shall be once and a half the breadth; and here it is precisely such. c, a pedestal or altar of the household god. C C, alæ. They were on three sides surrounded by seats, and, from Sir W. Gell's account, are analogous to similar recesses in the galleries of Turkish houses, with their divans: the thresholds were mosaic. Vitruvius directs them to be two sevenths of the length of the atrium; which is precisely their size here. D, tablinum. It was separated from the atrium by an aulæum, or curtain, like a drop scene. Next the inner court was sometimes, perhaps generally, a window, occupying the whole side. The tablinum was used as a dining-room in summer. E E E E, peristyle, which, in this example, exactly corresponds with the proportions directed by Vitruvius. F F F F were domestic apartments, as penaria, or cubicula, or cellæ domesticæ. G, probably the pinacotheca, or apartment for pictures. H, fauces, or passage of communication between the outer and inner divisions of the house. I, cubiculum. Its use cannot be doubted, as it contains a bedstead, filling up the whole width of the further end of it. K, triclinium, raised two steps from the peristyle, and separated from the garden by a large window. In this room company was received, and chairs placed for their accommodation. L L L, exedrae. M M M, cellæ familiaræ, or family chambers: the further one had a window looking into a court at d. N, lararium or armarium, a receptacle for the more revered and favourite gods. O, kitchen with stoves therein, and opening into a court at e, and an inner room P, in which were dwarf walls to deposit oil jars. Q, fauces conducting to the garden. Along the back front, R R R R, is a portico or pergula, for training vines and creepers on the back front of the house, before the windows of the triclinium. S S: these two rooms, opening into the pergula, were, it is presumed, cubicula. T T, &c.: the apartments thus marked seem to have constituted a distinct portion of the house, and communicated with the street by a separate door. That they were in-

253. Fig. 136. is a plan of the house of Pansia at Pompeii, by reference to which the reader will gain a tolerable notion of the situation of the different apartments whereof we have been speaking. A is the prothyrum,

dens, and had doors in the middle. It was made long, and broad enough to hold two triclinia opposite to each other. The Greek æcus was not, however, much used in Italy. The *pinacotheca* (picture room), where possible, faced the north: both this and the *bibliotheca* (library), whose aspect was east, do not require explanation. The *exedra* of the Roman houses were large apartments for the general purposes of society. The upper stories of the house, the chief being on the ground floor, were occupied by slaves, freedmen, and the lower branches of the family. Sometimes there was a *solarium* (terrace), which was, in fine weather, much resorted to.

cluded in the establishment of Pansa seems certain, from their being connected with the peristyle by the large apartment U. On excavating here, four skeletons of females were found marked by their gold ear-rings; also a candelabrum, two vases, a fine marble head of a faun, gold bracelets, rings with engraved stones, &c. &c. V V V are shops, which appear, by the remains of staircases, to have had apartments above. They contain dwarf walls for ranging oil jars and other goods against. W W, &c. are different shops. One is of a baker, and to it the necessary conveniences are appended. X X. apotheca or store-rooms. Y is the bakehouse, containing the oven Z, the mills, a kneading trough, &c.: it is paved with volcanic stone in irregular polygons. g g, place for the wood and charcoal. h appears to have been almost a distinct dwelling: two of the apartments had windows to the street, which runs southward to the forum. f f f, entrances from the street to the house of Pansa. The house was surrounded by streets, or, in other words, was an insula. We have thus named the principal apartments, and identified them by an example. In more magnificent houses there were the sacarium, the venereum, the sphæristerium, the aleatorium, &c. &c. The painting *fig. 137.* is in the kitchen of the house at Pansa, and represents the worship of the lares, under whose care and protection the provisions and cooking utensils were placed.

Fig. 137.

PAINTING AT POMPEII.

254. *Tombs.*—The Romans were rather given to magnificence in the tombs erected for their dead. Some of these were public, and others for the interment of individuals or families. The former were often of vast extent, and have been compared to subterranean cities; the others were pyramids, conical and cylindrical towers, with ranges of vaults in them for sepulture.

255. Perhaps the earliest tomb at Rome is that of the Horatii, which stands on the Apian Way, and was probably constructed by Etruscan workmen. It has a basement 45 ft. square on the plan, on which stand five masses of rubble or earth, faced with masonry, in the form of frusta of cones, four of which are ten feet diameter at the bottom, and are placed at the four angles of the basement. The fifth stands in the centre of the whole mass, and is larger than the others.

256. The principal tombs about Rome are, 1. The pyramid of Caius Cestius, whose sides are 102 ft. long, and its height about the same number of feet. The interior contains in the centre a rectangular cell, 20 ft. long, and 13 ft. broad. At each external angle of this pyramid stands a Doric column, without any portion of entablature over it. It is possible these were intended as ornaments, though it has often puzzled us to find out how they ever could have been so thought. 2. The tomb of Adrian, now converted into the Castel St. Angelo, had originally a square basement, whose sides were 170 ft. long. From this substructure rose a cylindrical tower, 115 ft. diameter, probably at one time encircled by a colonnade. It is now used as a fortress, and was considerably altered by Pope Paul III. 3. The mausoleum of Cecilia Metella is a circular building, 90 ft. in diameter, and 62 ft. high, standing on a basement of the same form. Up to the frieze the tomb is of Travertine stone, but the frieze itself is of marble, with sculptured rams' heads and garlands. In what may be called the core is a cell, 19 ft. diameter, to which there is an entrance by a passage on the exterior.

257. We do not, however, think it necessary further to detail the Roman tombs which may be found in Rome or the provinces, but, in lieu of extending our description on this

head, to give the reader a notion of their forms in *fig. 138.* by a group from Pompeii,

Fig. 138

TOMBS AT POMPEII.

among the remains of which city there are a great many and various examples. They are in general of small dimensions, and stand so near one another as to form a street, called the Street of the Tombs. Some of these are decorated very highly, both as respects ornament in the architecture and bassi relievi on the different faces. The Romans were particular in keeping alive the memory of the dead, hence their tombs were constantly looked after and kept in repair; a matter which, in this country of commerce and politics, a man's descendants rarely think of, after dividing the spoil at his death.

258. *Character of Roman Architecture.*—The character of the Roman architecture in its best period was necessarily very different from the Grecian, on which it was founded. We envy not those who say that they feel no beauties except those which the pure Grecian Doric of the Parthenon possesses. Each style, in every division of architecture, has its beauties; and those, among other causes, arise from each style being suited to the country in which it was reared; neither can we too often repeat the answer which Quatremère de Quincy gives in the *Encyclopedie Méthodique* to the question many years since propounded by the French Academy of Inscriptions and Belles Lettres, "Whether the Greeks borrowed their architecture from the Egyptians?" The answer of that highly talented writer is, "That there is no such thing as general human architecture, because the wants of mankind must vary in different countries. The only one in which the different species of architecture can approach each other is intellectual; it is that of impressions, which the qualities whose effects are produced by the building art can work upon the mind of every man, of every country. Some of them result from every species of architecture,—an art which sprung, as well from the huts of Greece, as from the subterraneous excavations of Egypt, from the tents of Asia, and from several mixed principles to us unknown. Thus the use of the word architecture is improper. We ought to name the species; for between the idea of architecture as a genus and as a species there is the same difference as between language and tongue; and to seek for a simple origin of architecture is as absurd as a search would be after the primitive language. If so, the hut of Vitruvius would be but an ingenious fable, as some have said; but it would be a ridiculous falsehood if he had pretended that it was the type of *all* architecture." If we must confine ourselves to the simplicity and purity of line which the Greek temple exhibits,—circumstances, be it observed, that no future occasion can ever again effectually call up,—all the admiration of the numberless monuments of the Romans is based upon false data, and we are not among those who feel inclined to set ourselves up against the universal consent of our race. Thus far we think it necessary to observe on the silly rage which a few years ago existed for setting up in this metropolis pure Greek Doric porticoes and pure Greek profiles. What could more exhibit the poverty of an artist's imagination, for instance, if the thing exist, than appending to a theatre the Doric portico of a temple? But the thing is too ridiculous to dwell on, and we proceed to our purpose. Whether the Romans invented the Tuscan order we much doubt. No example of it exists similar in formation to that described by Vitruvius: it must, however, be admitted that it is a beautiful combination of parts, and worthy so great a people. It seems highly probable that this order was used by the Etruscans, and that to them its origin is attributable. The use of timber in the entablature, which we know was practised by them to a great extent, seems to sanction such an hypothesis. Its detail, as well as that of the other orders of architecture, belong to another part of this work; we shall not therefore further speak of it than in the language of Sir Henry Wotton, who says, with his usual quaintness and simplicity, that it is a sturdy labourer in homely apparel.

259. The Doric order with the Romans was evidently not a favourite. In their hands its character was much changed. The remains of it in the theatre of Marcellus, in the examples at Cora and Pompeii, and the fragment at the baths of Dioclesian, are not sufficient, the case of the first only excepted, to justify us in detaining the reader on the matter. The

lower order of the Coliseum, be it observed, wants the triglyph, the distinguishing feature of the order; so that although in a previous page we have described it as Doric, we scarcely know whether we have not erred in our description. But to approach the subject of the Roman Doric more closely, we will examine the general form of the example which the theatre of Marcellus affords. Therein the whole height of the order is 31·15 ft. whereof the entablature is rather more than one fifth, and the columns are 7·86 diameters high. From the intercolumniations nothing can be deduced, because the arcade which separates puts them out of comparison with other examples. Its profile is clearly that which has formed the basis upon which the Doric of the Italian architects is founded; they have, however, generally added a base to it. There is great difference between it and the Grecian Doric, which in its form is much more pyramidal, and would, even in ancient Rome, have been out of character with the decorations applied in the architecture of the city, in which all severity of form was abandoned. The details, however, of the Roman as well as of the Grecian Doric will be given, and, from the representations, better understood by the reader, when we come to treat of the Orders in the third book of this work, where some varieties of it are submitted to the reader.

260. In the examples of Roman Ionic, that of the theatre of Marcellus excepted, there is a much greater inferiority than in the instance of Roman Doric to which we have just alluded; indeed, that of the Temple of Concord is composed in so debased a style, that it ought scarcely to be alluded to. The following table exhibits the general proportions of the four Roman profiles of it:—

	Height divided by lower Diameter in English Feet.	Diameters in Height.	Entablature in Terms of the Diameter.	Inter-columniation.	Height of Capital in Terms of the Diameter.	Upper Diameter of Shaft.
Fortuna Virilis (Temple of) -	$\frac{27.348}{3.109} =$	8·796	2·182	2·125	·457	·874
Concord (Temple of) -	$\frac{42.861}{4.486} =$	9·554	1·605	1·807	·500	·825
Marcellus (Theatre of) -	$\frac{23.040}{2.660} =$	9·000	2·391	- -	·557	·842
Coliseum - - -	$\frac{25.731}{2.91} =$	8·842	2·280	- -	·466	·833

261. From the above it appears that, except in the case of the Temple of Concord, the entablature is about one fifth of the height of the whole order, and that the column diminishes about  $\frac{16}{100}$  of its lower diameter. The capitals of the Roman are much smaller than those of the Grecian Ionic, and their curves are by no means so elegant and graceful. There is no appearance of refinement and care in their composition, than which the rules of Vitruvius give an altogether much more beautiful profile than those examples we have here quoted present. In the Temple of Concord, the volutes are placed diagonally on the capital, so that the four faces are similar in form. In the Greek specimens, as also in the Temple of Fortuna Virilis, this is done on one angle only of the capital of the columns, and that for the purpose of again bringing the faces of the volutes on to the flanks of the building, instead of showing the baluster sides of the capitals. On the whole, we think the modern Italian architects succeeded in producing much more beautiful profiles of this order, which never appears to have been a favourite in Rome, than their ancient predecessors.

262. The Corinthian seems to have been greatly preferred to the other orders by the luxurious Romans. There is little doubt that the capitals were generally the work of Greek sculptors, and some of those they have left are exceedingly beautiful; one that we have already mentioned, that of Jupiter Stator, points to sculpture of the highest class. The following table contains the general proportions of six well-known examples in Rome:—

	Height divided by lower Diameter in English Feet.	Diameters in Height.	Entablature in Terms of the Diameter.	Inter-columniation.	Height of Capital in Terms of the Diameter.	Upper Diameter of Shaft.
Pantheon, Portico - -	$\frac{47.022}{4.797} =$	9·804	2·317	2·092	1·175	·855
Pantheon, Interior - -	$\frac{24.674}{3.642} =$	9·499	2·251	1·834	1·000	·866
Jupiter Tonans - - -	$\frac{47.084}{4.598} =$	10·241	2·069	1·558	1·167	·867
Jupiter Stator - - -	$\frac{47.648}{4.841} =$	9·820	2·534	1·575	1·08	·891
Façade of Nero - - -	$\frac{65.5}{6.568} =$	9·973	2·439	- -	1·269	·883
Arch of Constantine - -	$\frac{28.937}{3.902} =$	9·661	2·388	- -	1·095	·882

263. From the above, it appears that a mean of the whole height of the Corinthian order in the Roman examples is 12·166 diameters, and that the entablature is less than a fifth

of the height of the order, being as 1686 : 10000. The diminution of the shaft is not so much as in the Ionic, being only  $\frac{124}{1000}$  of the lower diameter. The Temple of the Sybil at Tivoli presents quite a distinct species, and is the romance of the art, if we may be allowed such an expression. The mean height of the columns is 9.833 diameters, being rather slenderer than the height recommended by Vitruvius (Lib. iv. c. 9.). The attic base, which will be considered in another portion of the work, was frequently employed by the Roman artists.

264. The invention of the Composite order is attributed, with every probability, to the Romans. It resembles generally the Corinthian, the main variation consisting in the part above the second tier of leaves in the capital. The following table exhibits the general proportions of three examples : —

Example.	Height divided by lower Diameter in English Feet.	Diameters in Height.	Entablature in Terms of the Diameter.	Height of Capital in Terms of the Diameter.	Diameter at top of Shaft.
Arch of Titus - - -	$\frac{22.065}{2.07} =$	10.662	2.533	1.287	.887
Arch of Severus - - -	$\frac{23.547}{2.587} =$	8.260	2.316	1.144	.882
Baths of Dioclesian - -	$\frac{48.476}{4.619} =$	10.495	2.3	1.181	.802

265. The mean of these makes the entablature a little less than one fifth of the entire height of the order, the ratio being as 1955 : 10000. The diminution of the shaft is  $\frac{124}{1000}$  of the lower diameters. The mean height of the columns is 9.806 diameters. A strongly marked feature in Roman architecture is the stylobate or pedestal for the reception of columns, which was not used by the Greeks. In the examples, it varies in height, but, generally speaking, it is very nearly four diameters of the column; a mean of those used in the triumphal arches comes out at 3.86 diameters. Another difference from Greek architecture is in the form of the Roman pilaster, which was sometimes so strongly marked as to form a sort of square column with capitals and bases similar to those of the columns it accompanies, except in being square instead of circular on the plan. It is diminished in some buildings, as in the portico of the Pantheon, and in that of Mars Ultor, while in others, no such diminution takes place. The reader will recollect that the Greek *antæ* were never diminished, that their projection was always very small, and that the mouldings of their capitals were totally different from the columns with which they are connected.

266. But the most wonderful change the Romans effected in architecture was by the introduction of the arch; a change which, by various steps, led, through the basilica, to the construction of the extraordinary Gothic cathedrals of Europe, in its progress opening beauties in the art of which the Greeks had not the remotest conception. These matters will be more entered into in the next section: we only have to observe here, that its importance was not confined to the passage of rivers by means of bridges, but that it enabled the Romans to supply in the greatest abundance to their cities water of a wholesome quality, without which no city can exist. To the introduction, moreover, of the arch, their triumphal edifices were indebted for their principal beauties; and without it their theatres and amphitheatres would have lost half their elegance and magnificence. Whence the arch came is not known. In the section on Egyptian architecture, the subject has already been noticed. We are not aware of any example ornamentally applied before the time of Alexander.

267. The use of coupled columns and niches exhibits other varieties in which the Romans delighted; but the former are not found till an age in which the art of architecture had begun to decline.

268. There is still another point to which the reader's attention must be directed, and it is almost a sure test of Roman or Greek design; namely, the form of the mouldings of an order on their section. In purely Greek architecture, the contours of the mouldings are all formed from sections of the cone, whilst in that of the Romans, the contours are all portions of circles.

269. Under the climate of Rome it became necessary to raise the pitch of the roof higher than was necessary in Greece; hence the Roman pediment was more inclined to the horizon. As, however, we shall, in another place, when we consider the practical formation of roofs generally, investigate the law which, forced by climate upon the architect, governed the inclination of the pediment, the reader, for further information, is referred, on that point, to its proper place in this work; namely, that wherein the subject of roofs is treated of.

## SECT. XIV.

## BYZANTINE AND ROMANESQUE ARCHITECTURE.

270. We propose in this section to take a concise view of the state of debased Roman architecture, from the year 476, in which the Roman empire in the West was destroyed, to the introduction of the pointed arch at the latter end of the 12th century. It will be necessary to premise that the term Romanesque is very general, and comprises the works of the Lombards as well as those of a later species, which in this country are called Saxon and Norman, for the character of all is the same, and we think much confusion will be prevented by the arrangement we propose. Between the fifth and the eighth centuries, at the beginning of which latter period the whole of Europe formed one great Gothic kingdom, the prospect is over a dreary desert in which the *oases* of our art are few and far between. The constant change of power, the division of the empire, which was so overgrown that it could no longer hang together, the irruptions of the Goths, whose name has been most improperly connected with all that is barbarous in art, make it no easy task to give the unlearned reader more than a faint idea of what occurred in the extended period through which, often in darkness, we must proceed to feel our way. But, previous to this, we shall continue the state of the architecture in the East; because, having already given some account of Saracenic architecture, which had its origin about the seventh century, we shall not again have to divert his attention from the subject until the reader is introduced to the pointed style: an arrangement which, we trust, will assist his memory in this history.

271. The emperor Theodosius, who died A. D. 395, exhibited great talent in arms, and was desirous to extend the benefit of his influence to the arts, in which he did much for the empire. His sons, Arcadius in the city of Constantinople, and Honorius at Rome, were incapable of doing them any service, though by them was raised the famous Theodosian column at the first named city, which was surrounded with bassi relievi, after the fashion of that erected long before in honour of Trajan at Rome. The ascent of Theodosius II. to the throne promised as well for the empire as for the arts. He called architecture to his aid for embellishing the cities of the empire. Under him, in 413, Constantinople was surrounded with a new wall; some extensive baths, and a magnificent palace for the two sisters of Pulcheria were erected. In 447, an earthquake nearly destroyed the city, which was so admirably restored under this emperor that he might with propriety have been called its second founder. Except some trifling matters under Anastasius II., and Justin his successor, little was done till Justinian, the nephew of the last named, ascended the throne of the East, in 527. By him the celebrated architect Anthemius was invited to Constantinople. Through the genius of this artist, aided by his colleague Isidore the Milesian, on the ruins of the principal church of the city, which, dedicated to Saint Sophia or the Eternal Wisdom, had been twice destroyed by fire, was raised so splendid an edifice, that Justinian is said on its completion to have exclaimed, as Gibbon observes, "with devout vanity:" "Glory be to God, who hath thought me worthy to accomplish so great a work. I have vanquished thee, O Solomon." We shall make no apology for giving the description in the words of the historian we have just quoted; a representation of the building being appended in *figs.* 139. and 140. "But the pride of the Roman Solomon, before twenty years had elapsed, was

Fig. 139. PLAN OF CHURCH OF ST. SOPHIA.

humbled by an earthquake, which overthrew the eastern part of the dome. Its splendour was restored by the perseverance of the same prince; and in the thirty-sixth year of his reign, Justinian celebrated the second dedication of a temple, which remains, after twelve centuries, a stately monument of his fame. The architecture of St. Sophia, which is now converted into the principal mosque, has been imitated by the Turkish sultans, and that venerable pile continues to excite the fond admiration of the Greeks, and the more rational curiosity of European travellers. The eye of the spectator is disappointed by an irregular prospect of half domes and shelving roofs: the western front, the principal approach, is destitute of simplicity and magnificence; and the scale of dimensions has been much surpassed by several of the Latin cathedrals. But the architect who first erected an *aërial* cupola is entitled to the praise of bold design and skilful execution. The dome of St. Sophia, illuminated by four and twenty windows, is formed with so small a curve, that the

depth is equal to only one sixth of its diameter; the measure of that diameter is 115 ft.,

Fig. 140.

CHURCH OF SANTA SOPHIA. ELEVATION AND SECTION.

and the lofty centre, where a crescent has supplanted the cross, rises to the perpendicular height of 180 ft. above the pavement. The circle which encompasses the dome lightly reposes on four strong arches, and their weight is firmly supported by four massy piles" (piers), "whose strength is assisted on the northern and southern sides by four columns of Egyptian granite. A Greek cross inscribed in a quadrangle represents the form of the edifice; the exact breadth is 243 ft., and 269 may be assigned for the extreme length from the sanctuary in the east, to the nine western doors which open into the vestibule, and from thence into the *narthex* or exterior portico. That portico was the humble station of the penitents. The nave or body of the church was filled by the congregation of the faithful; but the two sexes were prudently distinguished, and the upper and lower galleries were allotted for the more private devotion of the women. Beyond the northern and southern piles" (piers), "a balustrade, terminated on either side by the thrones of the emperor and the patriarch, divided the nave from the choir; and the space, as far as the steps of the altar, was occupied by the clergy and singers. The altar itself, a name which insensibly became familiar to Christian ears, was placed in the eastern recess, artificially built in the form of a demi-cylinder, and this sanctuary communicated by several doors with the sacristy, the vestry, the baptistery, and the contiguous buildings, subservient either to the pomp of worship or the private use of the ecclesiastical ministers." We should be fearful of thus continuing the quotation, but that we prefer the language of Gibbon to our own; beyond which, the practical knowledge the rest of the description discloses is not unworthy the scientific architect, and the subject is the type of the great modern cathedrals, that of St. Paul, in London, among the rest. "The memory," he continues, "of past calamities inspired Justinian with a wise resolution, that no wood, except for the doors, should be admitted into the new edifice; and the choice of the materials was applied to the strength, the lightness, or the splendour of the respective parts. The solid piles" (piers) "which sustained the cupola were composed of huge blocks of freestone, hewn into squares and triangles, fortified by circles of iron, and firmly cemented by the infusion of lead and quicklime; but the weight of the cupola was diminished by the levity of its substance, which consists either of pumice-stone that floats in the water, or of bricks from the Isle of Rhodes, five times less ponderous than the ordinary sort. The whole frame of the edifice was constructed of brick; but those base materials were concealed by a crust of marble; and the inside of St. Sophia, the cupola, the two larger and the six smaller semi-domes, the walls, the hundred columns, and the pavement, delight even the eyes of barbarians with a rich and variegated picture." Various presents of marbles and mosaics, amongst which latter were seen representations of Christ, the Virgin, and saints, added to the magnificence of the edifice, and the precious metals in their purity imparted splendour to the scene. Before the building was four feet out of the ground its cost had amounted to a sum equivalent to 200,000*l.* sterling, and the total cost of it when finished may, at the lowest computation, be reckoned as exceeding one million. In Constantinople alone, the emperor dedicated twenty-

five churches to Christ, the Virgin, and favourite saints. These were highly decorated, and imposing situations were found for them. That of the Holy Apostles at Constantinople, and of St. John at Ephesus, appear to have had the church of St. Sophia for their types; but in them the altar was placed under the centre of the dome, at the junction of four porticoes, expressing the figure of the cross. "The pious munificence of the emperor was diffused over the Holy Land; and if reason," says Gibbon, "should condemn the monasteries of both sexes, which were built or restored by Justinian, yet charity must applaud the wells which he sank, and the hospitals which he founded, for the relief of the weary pilgrims." "Almost every saint in the calendar acquired the honour of a temple; almost every city of the empire obtained the solid advantages of bridges, hospitals, and aqueducts; but the severe liberality of the monarch disdained to indulge his subjects in the popular luxury of baths and theatres." He restored the Byzantine palace; but selfishness, as respected his own comfort, could not be laid to his charge: witness the costly palace he erected for the infamous Theodora, and the munificent gifts, equal to 180,000*l.* sterling, which he bestowed upon Antioch for its restoration after an earthquake. His care was not limited to the peaceful enjoyment of life by the empire over which he presided; for the fortifications of Europe and Asia were multiplied by Justinian from Belgrade to the Euxine, from the conflux of the Save to the mouth of the Danube; a chain of above fourscore fortified places was extended along the banks of the great river, and many military stations appeared to extend beyond the Danube, the pride of the Roman name. We might considerably extend the catalogue of the extraordinary works of Justinian; but our object is a general view, not a history of the works of this extraordinary person, of whom, applying the verses architecturally, it might truly be said —

Si Pergama dextra  
Defendi possent: etiam hac defensa fuissent; —

and by whom, if architecture could again have been restored, such a consummation would have been accomplished.

272. In 565 Justin succeeded to the throne of the East, after whose reign nothing occurs to prevent our proceeding to the Western part of the empire, except the notice necessary to be taken of Leo the Isaurian, who ordered the statues in the different churches to be broken in pieces, and the paintings which decorated them to be destroyed. Under him Ravenna was lost to the Eastern empire, and under his predecessors Mahomet appeared; and in his successors originated the Saracenic architecture described in a previous section. It was under Justin, in 571, that the prophet, as he is called, was born, and was in 632 succeeded by Abubekr.

273. We now return to the empire in the West, whose ruin, in 476, drew after it that of the arts, which had grievously degenerated since the fourth century, at which period their *decadence* was strongly marked. But we must digress a little by supplying a chasm in the history of our art relative to the ancient basilicæ of Rome, the undoubted types of the comparatively modern cathedrals of Europe; and within the city of Rome we shall find ample materials for tracing the origin whereof we speak.

274. The severe laws against the Christians which Severus had passed expired with his authority, and the persecuted race, between A. D. 211 and 249, enjoyed a calm, during which they had been permitted to erect and consecrate convenient edifices for the purposes of religious worship, and to purchase lands even at Rome for the use of the community. Under Dioclesian, however, in many places the churches were demolished, though in some situations they were only shut up. This emperor, as if desirous of committing to other hands the work of persecution he had planned by his edicts, no sooner published them, than he divested himself, by abdication, of the imperial purple.

\*275. Under Constantine, in the beginning of the fourth century, the Christians began again to breathe; and though that emperor's religion, even to the period of his death, is involved in some doubt, it is certain that his opinion, as far as we can judge from his acts, was much inclined towards Christianity. Out of the seven principal churches, or basilicæ, of Rome, namely, Sta. Croce di Gierusalemme, S. Giovanni Laterano, S. Lorenzo fuori le Mura, S. Paolo, S. Pietro, S. Sebastiano, and Sta. Maria Maggiore, all but the last were founded by Constantine himself. The ancient basilica, which derived its name from *basileus* (a king), and *oikos* (a house), was that part of the palace wherein justice was administered to the people. The building for this purpose retained its name long after the extinction of the kingly office, and was in use with the Romans as well as the Grecians. Vitruvius does not, however, give us any specific difference between those erected by one or the other of those people. In lib. v. c. 1. he gives us the details of its form and arrangement, for which the reader is referred to his work. The name of basilica was afterwards transferred to the first buildings for Christian worship; not because, as some have supposed, the first Christian emperors used the ancient basilicæ for the celebration of their religious rites, but more probably with reference to the idea of sovereignty which the religion exercised, though we do not assert that such conclusion is to be necessarily drawn.

There can be no doubt that the most ancient Christian basilicæ were expressly constructed for the purpose of religion, and their architectural details clearly point to the epoch in which they were erected. These new temples of religion borrowed, nevertheless, as well in their whole as in their details, so much from the ancient basilicæ, that it is not surprising they should have retained their name. We here place before the reader (*fig. 141.*) a plan of

Fig. 141.

PLAN OF THE BASILICA OF ST. PAUL.

the ancient basilica of S. Paolo fuori le Mura, and (*fig. 142.*) an interior view of it, whereby

Fig. 142.

INTERIOR OF BASILICA OF ST. PAUL.

its general effect may be better understood. The latter shows how admirably it was adapted to the reception of an extremely numerous congregation. The numberless columns which the ancient buildings readily supplied were put in requisition for constructing these basilicæ, whereof, adopting the buildings of the same name as the type, they proportioned the elevation to the extent of the plans, and, in some cases, decorated them with the richest ornaments. Instead of always connecting the columns together by architraves on their summit, which might not be at hand, arches were spanned from one to the other, on which walls were carried up to bear the roofing. Though the practice of vaulting large areas did not appear till a considerable time after the building of the first Christian basilicæ, it must be recollected that the Temple of Peace at Rome had previously exhibited a specimen of the profound knowledge of the Romans in the practice of vaulting: in that example, groined vaults of very large dimensions were borne on entablatures and columns. Nor does this knowledge appear to have been lost in almost the last stage of decline of Roman architecture under the emperor Dioclesian. In the baths of this emperor are to be seen not only groined vaults in three

divisions, whose span is nearly 70 ft., but at the back of each springer a buttress, precisely of the nature of a flying buttress, is contrived to counteract the thrusts of the vaulting.

276. In recording the annihilation of the arts on the invasion of Odoacer, at the end of the fifth and during the course of the sixth century, historians have imputed it to the Gothic nations, qualifying by this name the barbarous style which then degraded the productions of the arts. Correct they are as to the epoch of their ruin, which coincided truly enough with the empire of the Goths; but to this nation they are unjust in attributing the introduction of a barbarous style.

277. History informs us, that as soon as the princes of the Goths and Ostrogoths had fixed themselves in Italy, they displayed the greatest anxiety to make the arts again flourish, and but for a number of adverse circumstances they would have succeeded. Indeed, the people whom the Romans designated as barbarous, were inhabitants of the countries to the north and east of Italy, who actually acquired that dominion and power which the others lost. Instructed at first by their defeats, they ultimately acquired the arts of those who originally conquered them. Thus the Gauls, the Germans, the Pannonians, and Illyrians, had, from their submission to the Roman people, acquired quite as great a love for the arts as the Romans themselves. For instance, at Nîmes, the birthplace of Antoninus Pius, the arts were in a state of high cultivation; in short, there were schools as good out of as in Italy itself.

278. Odoacer, son of Edicon, the chief of a Gothic tribe, after obtaining possession of Rome in 476, preserved Italy from invasion for six years; and there is little doubt that one of his objects was the preservation of the arts. He was, however, stabbed by the hand, or at least the command, of his rival and successor, Theodoric, in 493. Theodoric, the son of Theodemir, had been educated at Constantinople, and though personally he neglected the cultivation of science and art, he was very far from insensible to the advantages they conferred on a country. From the Alps to the extremity of Calabria, the right of conquest had placed Theodoric on the throne. As respects what he did for the arts, no better record of his fame could exist than the volume of public Epistles composed by Cassiodorus, in the royal name. "The reputation of Theodoric," says Gibbon, "may repose with confidence on the visible peace and prosperity of a reign of thirty-three years; the unanimous esteem of his own times, and the memory of his wisdom and courage, his justice and humanity, which was deeply impressed on the minds of the Goths and Italians." The residence of Theodoric was at Ravenna chiefly, occasionally at Verona; but in the seventh year of his reign he visited the capital of the Old World, where, during a residence of six months, he proved that one at least of the Gothic kings was anxious to preserve the monuments of the nations he had subdued. Royal edicts were framed to prevent the abuses, neglect, or depredations of the citizens upon works of art; and an architect, the annual sum of two hundred pounds of gold, twenty-five thousand tiles, and the receipt of customs from the Lucrine port, were assigned for the ordinary repairs of the public buildings. Similar care was bestowed on the works of sculpture. Besides the capitals, Pavia, Spoleto, Naples, and the rest of the Italian cities, acquired under his reign the useful or splendid decorations of churches, aqueducts, baths, porticoes, and palaces. His architects were Aloysius for Rome, and Daniel for Ravenna, his instructions to whom manifest his care for the art; and under him Cassiodorus, for fifty-seven years minister of the Ostrogoth kings, was for a long period the tutelary genius of the arts. The death of Theodoric occurred in 526; his mausoleum is still in existence at Ravenna, being now called Sta. Maria della Rotunda. That city contains also the church of St. Apollinaris, which shows that at this period very little, if any, change had been made in the arrangement of large churches on the plan of the basilica. The front of the convent of the Franciscan friars in the same town, which is reputed to be the entrance to the palace, bears considerable resemblance to the Porta Aurea of Dioclesian, at Spalatro. These buildings are all in a heavy debased Roman style, and we are quite at a loss to understand the passage quoted by Tiraboschi, from Cassiodorus, who therein gives a particular description of the very great lightness and elegance of columns; thus—"Quid dicamus columnarum junceam proceritatem? Moles illas sublimissimas fabricarum quasi quibusdam erectis hastilibus contineri et substantiæ qualitate concavis canalibus excavatas, ut magis ipsas æstimes fuisse transfusas; alias ceris judices factum, quod metallis durissimis videas expolitum." (Lib. vii. Var. 15.) We know no examples of the period that bear out these assertions of Cassiodorus; on the contrary, what is known of this period indicates a totally different style.

279. If the successors of Theodoric had succeeded to his talents as well as his throne, and if they had been assisted by ministers like Cassiodorus, the arts and letters of Italy might have recovered; but, after the retirement of that minister, from the succession of Vitiges, towards 538, the arts were completely extinct. In 543-7, Rome was taken and plundered by Totila; and afterwards, in 553, this ill-fated city was again united to the Eastern empire by the talents of Belisarius and Narses.

280. From the year 568 up to the conquest of Italy by Charlemagne, in 774, the country was overrun by the Lombards, a people who quickly attained a high degree of civilization,

and were much given to the practice of architecture. Maffei, Muratori, and Tiraboschi have clearly proved that neither the Goths nor the Lombards introduced any particular style, but employed the architects whom they found in Italy. Fig 143. is the west end

Fig. 143.

ST. MICHAEL, PAVIA.

of the church of St. Michael, at Pavia, a work executed under the Lombards, and, therefore, here inserted as an example of style. The anxiety, however, of the Lombards to preserve the arts was not sufficient to prevent their increasing decay, which daily became more apparent. Not more than the Goths do they deserve the reproach for their treatment of and indifference to them. Besides fortifications and citadels for defence, they built palaces, baths, and temples, not only at Pavia, the seat of their empire, but at Turin, Milan, Spoleto, and Benevento. Hospitals under them began to be founded. The Queen Theodelinda, in particular, signalled her pious zeal in founding one at Monza, near Milan, her favourite residence, and endowing it in a most liberal manner.

281. In the eighth century the influence of the popes on the fine arts began to be felt. John VI. and Gregory III., at the commencement of the eighth century, showed great solicitude in their behalf. During this age the popes gained great temporal advantages, and their revenues enabled them to treat those advantages so as to do great good for Italy. In the ninth century Adrian I. signalled himself in this passion to such an extent, that Nicholas V. placed on his monument the inscription,—

*Restituit mores, moenia, templa, Domos.*

His works were many and admirable. Among those of great use, he constructed porticoes from the city to San Paolo and S. Lorenzo fuori le Mura.

282. Before we advance to the age of Charlemagne, it will be necessary to notice the church of St. Vitalis, at Ravenna, which we have reserved for this place on account of the singularity of its construction. It was erected, as is usually believed, under the reign of Justinian, in the sixth century. See *figs.* 144. and 145. The exterior walls are formed in a regular octagon, whose diameter is 128 ft. Within this octagon is another concentric one, 54 ft. in diameter, from the eight piers whereof (55 ft. in height) a hemispherical vault is gathered over, and over this is a timber conical roof. The peculiarity exhibited in the construction of the cupola is, that the spandrels are filled in with earthen vases; and that round the

Fig. 144. PLAN OF ST. VITALIS, RAVENNA.

Fig. 145.

SECTION OF ST. VITALIS, RAVENNA.

exterior of its base semicircular headed windows are introduced, each of which is subdivided into two apertures of similar forms. Between every two piers hemicylindrical recesses are formed, each covered by a semidome, whose vertex is 48 ft. from the pavement, and each of them contains two windows subdivided into three spaces by two columns of the Corinthian order, supporting semicircular-headed arches. Between the piers and the external walls are two corridors, which surround the whole building, in two stories, one above the other, each covered by hemicylindrical vaulting. The upper corridor above the vault is covered with a sloping or leanto roof. We have before noticed the introduction of vases in the spandrels at the Circus of Caracalla; and we cannot help being struck with the similarity of construction in the instance above cited. It fully bears out the observation of Möller (*Denkmäler der Deutschen Baukunst*), "that, though beauty of proportion seems to have been unappreciated in these ages, and architecture was confined within a servile imitation of the earlier forms, the art of compounding cement, the proper selection of building materials, and an intimate acquaintance with the principles of solid construction with which the ancients were so conversant, were fully understood."

283. The era of Charlemagne, which opened after the middle of the eighth century and continued into the early part of the ninth, gave rise to many grand edifices dedicated to Christianity. This extraordinary man, rising to extensive dominion, did much towards restoring the arts and civilisation. "Meanwhile, in the south-east," says an intelligent anonymous writer, "the decrepid Grecian empire, itself maintaining but a sickly existence, had nevertheless continued so far to stretch a protecting wing over them [the arts] that they never had there equally approached extinction. It seems probable that Charlemagne drew thence the architect and artisans who were capable of designing and building such a church as the cathedral of Aix-la-Chapelle, in Germany." "If Charlemagne," says Gibbon, "had fixed in Italy the seat of the Western empire, his genius would have aspired to restore, rather than violate, the works of the Cæsars; but as policy confined the French monarch to the forests of Germany, his taste could be gratified only by destruction, and the new palace and church of Aix-la-Chapelle were decorated with the marbles of Ravenna and Rome." The fact is, that the Byzantine or Romanesque style continued, with various degrees of beauty, over the Continent, and in this country, till it was superseded by the introduction of the pointed style. Möller, from whom we extract *fig. 146.* which represents the portico of the Convent of Lorsch, situate about two and a half German miles from Darmstadt, considers it as all that remains of the first church built in the time of Charlemagne. The same learned author observes, that, on comparison with each other of the ancient churches of Germany, two leading differences are discoverable in their styles, of which all others are grades or combinations. The *first*, or earliest, whose origin is from the South, is, though in its later period much degenerated, of a highly finished character, distinguished by forms and decorations resembling those of Roman buildings, by flat roofs, by hemicylindrical vaults, and by great solidity of construction. The *second* and later style still preserves the semicircular forms; but the high pitched roof, more adapted to the seasons

Fig. 146.

PORTICO OF ST. MARK.

of a northern climate, begins to be substituted for the flat roof of the South, as at the cathedral of Worms on the west side, the western tower of the church at Gelnhausen, and in many other examples.

284. We are now approaching a period in which more light can be thrown on our subject than on that we have just quitted. In the ninth century, on, as it is said, the designs of a Greek artist, rose the cathedral of St. Mark at Venice, the largest of the Italian churches in the Byzantine style. Its plan is that of a Greek cross, whose arms are vaulted hemicylindrically, and, meeting in the centre of the building, terminate in four semicircular arches on the four sides of a square, about 42 ft. in length in each direction. From the anterior angles of the piers, *pendentives* gather over, as in St. Sophia, at Constantinople, and form a circle wherefrom rises a cylindrical wall or drum in which windows for lighting the interior are introduced. From this drum, the principal dome, which is hemispherical, springs. Longitudinally and transversely the church is separated by ranks of columns supporting semicircular arches. The aisles of the nave and choir, and those of the transepts, intersect each other in four places about the centre of the cross, over which intersections are small domes; so that on the roof are four smaller and one larger dome. In the exterior front towards the Piazza San Marco, the façade consists of two stories, in the centre of the lower one whereof is a large semicircular arched entrance, on each side of which are two other smaller arched entrances of the same form. These have all plain archivolts springing from the upper of two orders of columns. On each flank of the façade is a smaller open arcade springing at each extremity from an upper of two orders of insulated columns. A gallery with a balustrade extends round the exterior of the church, in front whereof, in the centre, are the four famous bronze horses which once belonged to the arch of Nero. The second story towards the Piazza San Marco consists of a central semicircular aperture, with two blank semicircular arches on each side, not quite so high and wide. These five divisions are all crowned by canopy pediments of curves of contrary flexures, and ornamented with foliage. Between each two arches and at the angles a turret is introduced consisting of three stories of columns, and terminated by a pinnacle. The building has been considerably altered since its first construction; and, indeed, the ornaments last named point to a later age than the rest of the edifice, the general character of which has, nevertheless, been preserved. There is considerable similarity of plan between this church and that of St. Sophia.

285. Very much partaking the character of composition of St. Mark, but dissimilar in

general plan, is the church of St. Anthony at Padua, which has six domes over the nave, transepts, centre, and choir. It is, moreover, distinguished by two slender towers or minarets, which impart to it the air of a Saracenic edifice.

286. The Italian architecture in the Byzantine or Romanesque style preserved a very different sort of character from that of the same date in Germany and other parts of Europe. Thus,—taking the cathedrals of Pisa and Worms, whose respective periods of construction are very close together,—the former is separated into its nave and aisles by columns with Corinthian capitals, reminding one very much of the early Christian basilica; in the latter, the separation of the nave from the aisles is by square piers. The cathedral at Pisa, with its baptistery, campanile, and the campo santo or cemetery, are a group of buildings of more curiosity than any four edifices in the world, and the more so from being so strongly marked with the distinguishing features of the Byzantine and Romanesque styles. The cathedral (*fig. 147.*), whose architect was Buschetto of Dulichio, a Greek, was built in the

beginning in the 11th century. It consists of a nave, with two aisles on each side of it, transepts, and choir. Its bases, capitals, cornices, and other parts were fragments of antiquity collected from different places, and here with great skill brought together by Buschetto. The plan of the church is a Latin cross; its length from the interior face of the wall to the back of the recess is 311 ft., the width of the nave and four side aisles 106 ft. 6 in., the length of the transept 237 ft. 4 in., and its width, with its side aisles, 58 ft. The centre nave is 41 ft. wide, and has twenty-four Corinthian columns, twelve on each side, all of marble, 24 ft. 10 in. high, and full 2 ft. 3 in. in diameter. From the capitals of these

Fig. 147. ELEVATION OF CATHEDRAL AT PISA.

columns arches spring, and over them is another order of columns, smaller and more numerous, from the circumstance of one being inserted over the centre of an intercolumniation below, and from their accompanying two openings under arches nearly equal to the width of such intercolumniations. These form an upper gallery, or *triforium*, anciently appropriated to the use of females. The four aisles have also isolated columns of the Corinthian order, but smaller, and raised on high plinths, in order to make them range with the others. The transepts have each a nave and two side aisles, with isolated columns, the same size as those of the other. The soffit of the great nave and of the transepts is of wood, gilt, but the smaller ones are groined. The height of the great nave is 91 ft., that of the transepts about 84 ft., and that of the aisles, 35 ft. In the centre nave are four piers, on which rest four large arches, supporting an elliptical cupola. The church is lighted by windows above the second order of the interior. The edifice is surrounded by steps. The extreme width of the western front, measured above the plinth moulding, is 116 ft., and the height from the pavement to the apex of the roof is 112 ft. 3 in. The façade has five stories, the first whereof consists of seven arches, supported by six Corinthian columns and two pilasters, the middle arch being larger than the others: the second has twenty-one arches, supported by twenty columns and two pilasters; the third is singular, from the façade contracting where the two aisles finish, and forming two lateral inclined planes, whence in the middle are columns with arches on them as below. The columns which are in the two inclined planes gradually diminish in height: the fifth story is the same, and forms a triangular pediment, the columns and arches as they approach the angles becoming more diminutive. The two exterior sides have two orders of pilasters, one over the other. The roof of the nave is supported, externally, by a wall decorated with columns, and arches resting on their capitals. The whole of the building is covered with lead. The drum of the cupola is externally ornamented with eighty-eight columns connected by arches, over which are pediments in marble, forming a species of crowns. The principal point of difference in these cathedrals from the old basilicæ, in imitation whereof they were doubtless built, is in the addition of the transepts, by which a cruciform plan was given to these edifices. The style of the building in question is much lighter than most of the buildings of the period. But, whatever the taste

and style, the architect of it was a very skilful mechanic. One of his epitaphs, at Pisa, we subjoin, in proof of what we have stated.

Quod vix mille boum possent juga juncta movere,  
Et quod vix potuit per mare ferre ratis,  
Buschetti nisu, quod erat mirabile visu,  
Dena puellarum turba levavit onus.

287. In Germany, the 10th and 11th centuries afford some edifices very important in the history of the art. Such are the cathedrals of Spire, Worms, Mayence, and others, still in existence to testify their extraordinary solidity and magnificence. In that country, as Möller remarks, there was a great disparity between its several provinces, as respected their degrees of civilisation. On the banks of the Rhine, and in the south, cities were established when those parts became subject to the Romans, and there the arts of peace and the Christian religion took root, and flourished; whilst, in the north and east, paganism was still in existence. Christianity, indeed, and civilisation gradually and generally extended from the southern and western parts. The clergy, we know from history, themselves directed the building of churches and convents. The buildings, therefore, of these parts are of great importance in the history of architecture. The leading forms of these churches, as well as of those that were built about the same period in France and England, are founded upon the ancient basilicæ; that is, they were long parallelograms with side aisles, and transepts which represent the arms of the cross, over whose intersection with the nave there is frequently a *lowvre*. The choir and chancel terminate semicircularly on the plan. The semicircle prevails in the vaultings and over openings. The nave is lofty, frequently covered with groined vaulting, sometimes with flat timber covering; the gables are of small inclination. In the upper parts small short columns are frequently introduced. The prevailing feature in the exterior is horizontality, by which it is distinguished from the style which came into use in the 13th century. The profiles of the mouldings are, almost without exception, of Roman origin; the impost mouldings under the arches are, in this respect, peculiarly striking; and among the parts the Attic base constantly appears. The Roman basilicæ were always covered with flat horizontal ceilings; those of the churches we are speaking of are mostly vaulted. Hence the necessity of substituting pillars or piers for the insulated columns, which had only to carry wooden roofs. There are, however, a few churches remaining, which preserve the ancient type, as a church at Ratisbon, and the conventual churches of Paulinzell and Schwarzach. *Fig. 148.* shows the plan, and *fig. 149.* a sketch of one bay in a

PLAN OF CATHEDRAL AT WORMS.

Fig. 148.

Fig. 149. ONE BAY OF NAIVE AT WORMS.

longitudinal section of the north side of the nave of the cathedral at Worms, which was commenced in the year 996, and consecrated in 1016. It is one of the most ancient of the German churches, and one of the most instructive. On our examination of it, recently, we were astonished at its state of preservation. The plan, it will be seen, is strongly distinguished by the cross; the square piers are alternately decorated with half columns; and the chancel, at the east end, terminates with a semicircle. The western end of the church, which is octagonal, appears more modern than the rest, inasmuch as the pointed arch appears in it. *Fig. 150.* is the general appearance of the building.

288. Parts of the cathedral at Mentz are more ancient than any part of that at Worms; hence it may be studied with advantage, as containing a view of the styles of several centuries. The south-eastern gate of the cathedral is given by Möller in his work (Plate VI.).

289. Whittington, a highly talented author, of whom the world was deprived at a very early age (*Historical Survey of the Ecclesiastical Antiquities of France*, 4to. Lond. 1809), observes, that the buildings in France of the 9th and 10th centuries were imi-

Fig. 150.

WORMS CATHEDRAL.

tated from the works of Charlemagne; but that his feeble successors, deficient both in riches and power, were unable to equal them in magnitude or beauty of materials. During a large portion of the 9th century the country was a scene of consternation and bloodshed. The most celebrated, and almost the only foundation of consequence which took place during this dreary period, was the abbey of Clugny. It was built, about 910, by Berno, abbot of Balme, with the assistance of William, Duke of Aquitaine and Auvergne. But there is little doubt that the present church was built in the following century. During the 11th century, the French, relieved from their disordered state, hastened to rebuild and repair their ecclesiastical structures, and their various

cities and provinces vied with each other in displays of enthusiastic devotion. Robert the Pious, by his example, encouraged the zeal of his clergy and people; and the science of architecture revived with majesty and effect from its fallen state. Morard, the abbot of St. Germain des Prés, was enabled by this monarch to rebuild the church of his convent on a larger scale. St. Geneviève was also restored, and a cloister added to it, by his order. He, moreover, made preparations for erecting a cathedral at Paris in a style of as great magnificence as the times would allow. At Orleans, the place of his nativity, he built the churches of Nôtre Dame de bonnes nouvelles, St. Peter, and St. Aignan, which last was consecrated in 1029. But our space does not allow an enumeration of all the works undertaken during his reign. About this time, the cathedral of Chartres was rebuilt by Fulbert, its bishop, whose great reputation, in France and the rest of Europe, enabled him to execute it in a manner till then unknown in his country. Canute, the king of England, and Richard, Duke of Normandy, were among the princes who assisted him with contributions. His successor, Thierri or Theodoric, completed the building. The northern part was afterwards erected in 1060, at the expense of Jean Cormier, a native of Chartres, and physician to the king. The length of the church is 420 ft., its height 108 ft., and the nave 48 ft. wide. The transepts extend 210 ft. The abbey church of Clugny, which succeeded that above mentioned, is one of the largest and most interesting of the ecclesiastical monuments of France, and was begun in the commencement of the 11th century, by the abbot Odilo, and finished by his successor Hugh, in 1069. The ceremony of its dedication did not, however, take place till many years after. The style of architecture in France, in the 11th, was the same as in the preceding centuries; but the churches were larger and more solidly constructed. The oldest buildings of France now existing, with some exceptions, are traceable to this æra; such are the venerable fabrics of St. Germain des Prés, St. Benigne at Dijon, those of Chartres, La Charité sur Loire, Clugny, and others; all remaining to illustrate the history of the arts of this period. But, as we have said before, and to the student the observation cannot be too often repeated, the style which prevailed was no more than a debased and feeble attempt to imitate the ancient architecture of Rome, and its best examples are not, in style even, equal to those of the art in its lowest state under the reign of Dioclesian; indeed the investigation is only important as being one of the means by which we can arrive at a just conclusion on the state of civilisation at different periods. *Mores fabrica loquuntur* is an expression of Cassiodorus, so true, that to prove it would indeed be lighting the sun with a candle; and we must not trifle with the patience of the reader.

290. The Saxon churches of England, to which and its more modern architecture our succeeding chapter will be entirely devoted, were very inferior in every respect to the Norman churches of France; and these latter differed materially from those in the neighbourhood of Paris, and further to the south. The Norman churches were larger in some examples; but they were more rude in design and execution. The abbey church of St. Stephen, raised at Caen by William the Conqueror, and that founded by his Queen Matilda in the same city in honour of the Holy Trinity, are the chief examples of the peculiar manner of building introduced by the Norman prelates into England at the end

of the 11th century; after which, as we shall presently see, a new and extraordinary style made its appearance in Europe, a style whereof *fig. 151.* will, on inspection, sufficiently give a general notion to the reader.

Fig. 151. NINTH TO TWELFTH CENTURY.

AFTER TWELFTH CENTURY.

291. Before leaving the subject of this section, we must fall back again upon Italy to notice two or three works intimately connected with this period of the art. We here more particularly allude to the celebrated baptistry and campanile of Pisa, a city which seems to have been a great nursing mother to our art, no less than to those of painting and sculpture. The Campo Santo of that city, of which, from the number of examples to be noticed, we regret we shall be unable to give but a short account, belongs to the next period, and must be noticed after them.

292. Diotti Salvi, whose birthplace even is unknown, commenced, in 1152, the baptistry of Pisa (*fig. 152.*), and after eight years completed it.

Fig. 152.

BAPTISTRY OF PISA.

It is close to the cathedral of the place, and though on the wall of the inner gallery there be an inscription, cut in the character of the middle ages, "A. D. 1278, *ÆDIFICATA FUIT DE NOVO*," and it may be consistent with truth that the edifice was ornamented by John of Pisa, there is nothing to invalidate the belief that the building stands on the foundations originally set out, and that for its principal features it is indebted to the architect whose name we have mentioned. It is 100 ft. in diameter within the walls, which are 8 ft. 6 in. thick. The covering is a double brick dome, the inner one conical, the outer hemispherical. The former is a frustum of a pyramid of twelve sides. Its upper extremity forms a horizontal polygon, finished with a small parabolic cupola, showing twelve small marble ribs on the exterior. The outer vault terminates above, at the base of the small cupola, which stands like a lantern over the aperture. From the pavement, the height of the cupola is 102 ft. The entrance is by a decorated doorway, from the sill of which the general pavement is sunk three steps round the build-

ing; the space between the steps and the wall having been provided for the accommodation of the persons assembled to view the ceremony of baptism. An aisle or corridor is continued round its interior circumference, being formed by eight granite columns and four piers, from which are turned semicircular arches, which support an upper gallery; and above the arches are twelve piers, bearing the semicircular arches which support the pyramidal

dome. On the exterior are two orders of Corinthian columns engaged in the wall, which support semicircular arches. In the upper order the columns are more numerous, inasmuch as each arch below bears two columns above it. Over every two arches of the upper order is a sharp pediment, separated by a pinnacle from the adjoining ones; and above the pediments a horizontal cornice encircles the building. Above the second story a division in the compartments occurs, which embraces three of the lower arches; the separation being effected by piers triangular on the plan, crowned by pinnacles. Between these piers, semicircular headed small windows are introduced, over each of which is a small circular window, and thereover sharp pediments. Above these the convex surface of the dome springs up, and is divided by twelve ribs, truncated below the vertex, and ornamented with crockets. Between these ribs are a species of dormer windows, one between every two ribs, ornamented with columns, and surmounted each by three small pointed pediments. The total height is about 179 ft. The cupola is covered with lead and tiles; the rest of the edifice is marble.

293. The extraordinary campanile, or bell tower, near the cathedral at Pisa, was built about 1174. It is celebrated from the circumstance of its overhanging upwards of thirteen feet, a peculiarity observable in many other Italian towers, but in none to so great an extent as in this. There can be no doubt whatever that the defect has arisen from bad foundation, and that the failure exhibited itself long before the building was completed; because, on one side, at a certain height, the columns are higher than on the other; thus showing an endeavour on the part of the builders to bring back the upper part of the tower to as vertical a direction as was practicable, and recover the situation of the centre of gravity. The tower is cylindrical, 50 ft. in diameter, and 180 ft. high. It consists of eight stories of columns, in each of which they bear semicircular arches, forming open galleries round the story. The roof is flat, and the upper story contains some bells. The last of the group of buildings in Pisa is the Campo Santo, which, from its style and date (1278), is only mentioned here out of its place in order to leave this interesting spot without necessity for further recurrence to it. It is the public burying-place of the city, and, whether from the remains on its walls of the earliest examples of Giotto, and Cimabue, the beauty of its proportions, or the sculpture that remains about, is unparalleled in interest to the artist. It is a quadrangle, 403 ft. in length, 117 ft. in width, and is surrounded by a corridor 32 ft. in breadth. This corridor is roofed, forming a sort of cloister with semicircular-headed windows, which were at first simple apertures extending down to the pavement, but they have been subsequently divided into smaller apertures by columns, which, from the springing of the arches, branch out into tracery of elegant design. The interior part of the quadrangle is open to the sky. Some of the arches above mentioned were completed as late as the year 1464.

## SECT. XV.

### POINTED ARCHITECTURE.

294. About the end of the 12th and the beginning of the 13th century, a most singular and important change took place in the architecture of Europe. The flat southern roof, says Möller, was superseded by the high pitched northern covering of the ecclesiastical edifices, and its introduction brought with it the use of the pointed arch, which was substituted for the semicircular one; a necessary consequence, for the roof and vaults being thus raised, the character of the whole could not be preserved without changing the whole arrangement of the combinations of forms. But we have great doubts on Möller's hypothesis; it will, indeed, be hereafter seen we have a different belief on the origin of the pointed arch. Before we at all enter upon the edifices of the period, we think it will be better to put the reader in possession of the different hypotheses in which various writers have indulged, relative to the introduction or invention of the pointed arch; and though we attach very little importance to the discovery, if it could now be clearly established, we are, as our work would be incomplete without the notice, compelled to submit them for the reader's consideration.

295. 1. *Some have derived this style from the holy groves of the early Celts.* — But we can see no ground for this hypothesis, for it was only in the 14th and 15th centuries that ribs between the groins (which have been compared to the small branches of trees) were introduced; hence it is rather difficult to trace the similarity which its supporters contend for.

296. 2. *That the style originated from huts made with twigs and branches of trees intertwined.* — An hypothesis fancifully conceived and exhibited to the world by Sir James Hall, in some very interesting plates attached to his work. Möller properly observes upon this theory of twigs, that it is only in the buildings of the 15th and 16th centuries that the supposed imitation of twigs appears.

297. 3. *From the framed construction of timber buildings.* — This is an hypothesis which it would be loss of time to examine, inasmuch as all the forms and details undoubtedly arise from the vault and arch; and a close examination of the buildings of the 13th century proves that the ancient ecclesiastical style involves the scientific construction of stone vaulting, all timber construction being limited to the framing of the roof.

298. 4. *From the imitation of the aspiring lines of the pyramids of Egypt.* — This hypothesis is the fancy of Murphy, the ingenious and useful editor of a work on the convent of Batalha, in Portugal, and also of some of the finest edifices of the Moors in Spain. The following is the reasoning of the author: — The pyramids of the Egyptians are tombs; the dead are buried in churches, and on their towers pyramidal forms are placed; consequently, the pyramids of the towers indicate that there are graves in the churches; and as the pyramidal form constitutes the essence of the pointed arch style, and the pyramids of the towers are imitations of the Egyptian pyramids, the pointed arch is derived from the latter. The reader, we are sure, will not require from us any examination of the series of syllogisms here enumerated.

299. 5. *From the intersection of semicircular arches which occurs in late instances of the Romanesque style.* — This was the hypothesis of the late Dr. Milner, a Catholic bishop of great learning and most amiable bearing, and a person so intimately acquainted with the subject on which he wrote, that we regret his reasons for the conjecture are not satisfactory to us, albeit the combination (fig. 153.) whereof he speaks is, in the Romanesque style, of frequent occurrence. The venerable prelate seems

FIG. 153. MILNER'S ORIGIN OF THE POINTED ARCH.

to have lost sight of a principle familiar to every artist — that in all art the details of a style are subordinate to and dependent on the masses, and that the converse never occurs; how, then, could the leading features of a style so universal have had their origin in an accidental and unessential decoration, like that of the theory in question? None of the above hypotheses are satisfactory;

and Möller well observes, that the solution of the question, whether the pointed style belongs to one nation exclusively, is attended with great difficulties. And it may be said that the problem for solution is not, who invented the pointed arch, but, in what way its prevalence in the 13th century is to be accounted for.

300. We are not of opinion that it is of much importance that this *veraxa questio* should be settled; and that it will now satisfactorily be done, we consider very much out of the limits of probability. But we suppose that the reader will be inclined to ask for our own bias on the subject; and, as we are bound to answer such a question, the reply is, that we are of the faith of the Rev. Mr. Whittington, to whose work we have before referred, that the pointed arch was of Eastern extraction, and that it was imported by the first crusaders into the West. "All eastern buildings," says that ingenious writer, "as far back as they go (and we cannot tell how far), have pointed arches, and are in the same style; is it not fair to suppose that some of these are older than the 12th century, or that the same style existed before that time? Is it at all probable that the dark ages of the West should have given a mode of architecture to the East?" Lord Aberdeen, whose taste and learning in matters of this nature well qualified him for the posthumous introduction to the public of the author we are using, observes, in his preface to Whittington's work, that, "if we could discover in any one country a gradual alteration of this style [the Romanesque], beginning with the form of the arch, and progressively extending to the whole of the ornaments and general design; — after which, if we could trace the new fashion slowly making its way, and by degrees adopted by the other nations of Europe; — the supposition of Mr. Walpole [that it arose from what was conceived to be an improvement in the corrupt specimens of Roman taste then exhibited, and was afterwards gradually carried to perfection] would be greatly confirmed. Nothing, however, of this is the case. We find the Gothic [pointed] style, notwithstanding the richness and variety it afterwards assumed, appearing at once with all its distinctive marks and features, not among one people, but, very nearly at the same period of time, received and practised throughout Christendom. How will it be possible to account for this general and contemporary adoption of the style, but by a supposition that the taste and knowledge of all on this subject were drawn from a common source? and where can we look for this source but to the East, which, during the crusades, attracted a portion of the population, and, in a great degree, occupied the attention, of the different states of Europe?" This was an opinion of Sir Christopher Wren, at least greatly so, his leaning being rather to deducing the origin of the style from the Moors in Spain. It is the fashion of modern half-educated critics to place little reliance on such authorities as Wren. We have, from experience, learned to venerate them. The noble author whom we have been quoting proceeds by stating that "the result receives confirmation from the circumstance of there being no specimen of Gothic [pointed] architecture erected in the West before the period in question." Exception, however, is to be made for the rare occurrence of a very few examples,

whose construction may perhaps be placed higher than the 12th century, and the cause of whose existence may be satisfactorily explained. "It may be sufficient here to observe, that no people versed in the science of architecture could long remain ignorant of the pointed form of the arch, the most simple and easy in construction, as it might be raised without a centre by the gradual projection of stones placed in horizontal courses; and, whether produced by accident or necessity, we may reasonably expect to meet with it occasionally in their works." It is certain that, though neglected in their general practice, the ancients were acquainted with this mode of building; and the occurrence of an arch merely pointed and unaccompanied with any other characteristic of the style, is no better evidence of the prevalence of Gothic (pointed) architecture, than that the appearance of Corinthian capitals in Romanesque buildings must give them the right to be called classical edifices. It is not easy to answer the question, — In what part of the East are we able to point to buildings constructed in the pointed style, of a date anterior to those erected in the West? A little reflection, however, will solve the difficulty; and here we must again trespass on the author we have so copiously used, though our limits will not allow us to follow him in his own words. It is manifest that the frequent wars and revolutions of the East entailed the same fate on works of art and utility as attended the princes and chiefs of the states subverted. Thus the number of architectural examples, and especially those of early date, was greatly diminished. Again, the people of the East with whom we are best acquainted, in a great measure sacrificed their less durable mode of building to that which they found established by the Greeks. Thus, the church of Santa Sophia was a model, after the conquest of Constantinople, for all the mosques that were erected, with the addition occasionally of minarets more or less lofty, as the piety and magnificence of the sultans might dictate. Previously to the conquest of the metropolis of the East, such a practice was prevalent, and in the cities of the empire many christian edifices were adapted to the purposes of Mohammedan worship. Yet, notwithstanding these causes, which form an impediment to full information on the state of the early architecture of the East, there is an abundance of facts to give probability to our notion, except in the eyes of those who view the subject through the medium of prejudice and established system; at least so we opine.

301. "If a line," says our author, "be drawn from the north of the Euxine, through Constantinople to Egypt, we shall discover in every country to the eastward of this boundary frequent examples of the pointed arch, accompanied with the slender proportions of Gothic [pointed] architecture; in Asia Minor, Syria, Arabia, Persia; from the neighbourhood of the Caspian, through the wilds of Tartary; in the various kingdoms, and throughout the whole extent of India, and even to the furthest limits of China. It is true that we are unable, for the most part, to ascertain the precise date of these buildings; but this in reality is not very important, it being sufficient to state the fact of their comparative antiquity, which, joined to the vast diffusion of the style, appears adequate to justify our conclusion. Seeing, then, the universal prevalence of this mode in the East, which is satisfactorily accounted for by the extensive revolutions and conquests effected by Eastern warriors in that part of the world, it can scarcely appear requisite to discuss the probability of its having been introduced from the West, or, still less, further to refute the notions of those who refer the origin of the style [as some have very ignorantly done] to the invention of English artists. Had it been adopted from the practice of the West, such a peculiarity of taste and knowledge must have been imparted by some general communication: this has only occurred at one period, during which no building of the species in question existed in Europe. The inhabitants of the West could not convey a knowledge which they did not possess; but, as it became pretty general amongst them shortly after the epoch alluded to, it is reasonable to infer that they acquired it from those nations they are said to have instructed. On the whole, it is probable that the origin of the Gothic style, notwithstanding the occasional imitation of a corrupt and degraded species of Roman architecture, is sufficiently indicated by the lofty and slender proportions, by the minute parts, and the fantastic ornaments of Oriental taste."

302. Möller, a writer for whose opinions we entertain the highest respect, is not, however, of opinion that the pointed arch originated with the Arabs; and he observes that a scrutiny of their buildings will exhibit nothing that bears upon the Gothic, or pointed, style. He says that their arches are in the shape of a horseshoe; that the columns are low, that they stand single, and are not connected in groups; that the windows are small, the roofs flat, and that the prevalent general forms are horizontal: that, in the ancient churches of the 13th century, the arches are pointed, the pillars high and composed of several columns, windows large, and roofs and gables high. But at the end of his argument he admits that the solution of the question, "which of the European nations first introduced or improved the pointed style is not so easy, for we find this style of building almost contemporary in all parts of Europe." Now, though we are not about to use the argument which is not always valid, *post hoc ergo propter hoc*, we must observe, that the introduction of the pointed arch immediately after the first Crusade, and not before, is a most singular occurrence; and we are inclined to give it the same force as that used by old Bishop

Latimer on the subject of the Goodwin Sands and Tenterden steeple. One of the points of Möller's reasoning we do not think at all fortunate; it is that on the forms of the Moresque arches. Now, it must immediately occur to the reader that one of the forms (as at the side), and that a common one, is to be found in their arches, that of contrary flexure; a form in the architecture of this country in the time of the Tudors universally adopted, though, it must be allowed, much flattened in the application. Another point seems to have been altogether overlooked by Möller, namely, the practice of *diapering* the walls, whereof an instance occurs in Westminster Abbey; and one which has a very strong affinity to the practice of the Moors, who left no space unornamented. The higher-pitched gables of the northern roofs, we admit, fostered the discovery, by the introduction of forms from necessity, which were admirably calculated to carry out to their extreme limits the principles of which the Crusaders had acquired some notion for practice on their return to their respective countries. As to the objection that the Arabs had no original architecture, it is admitted. They must, however, have had that of the tent, whose form inverted would give all that is sought. These observations we do not throw out, however, as partisans; because, as we have before said, the satisfactory settlement of the origin involves nothing more than a silly antiquarian controversy, of importance to no one, and, if decided, gratifying only to little minds; and we ought, perhaps, to apologise, under such circumstances, to the reader, for having so long delayed his entry to the acquaintance with its examples. We cannot, however, proceed to that part of our duty without observing that the hypothesis adopted by us is sanctioned, in addition to the intelligent author upon whom we have drawn so much, by Warburton, and T. Warton, and Sir Christopher Wren; and though none of these had the opportunity of basing their opinions upon the labours of the recent travellers whom we have been able to use, we do not think, upon this mooted question, either of them would be reduced to the necessity of retracting what he has respectively written. The reader who is inclined to read the lucubrations of Mr. Kerrich of Cambridge, which deduce the forms of churches, arches, and perhaps many other objects, from the bladder of a fish (*vesica piscis*), may consult the *Archæologia*; in which, as respects that subject, much money was uselessly and ridiculously expended in text and plates, to illuminate the world on a subject whereof the writer was most profoundly ignorant. In the Appendix, page 825., will be found a short inquiry into this singular infatuation of a quasi sect, and it is hoped that the examination of the various *vesica piscium*, will have some tendency to put to rest one of the most singular theories ever propounded. Where the object of speculation is to eliminate truth, much allowance may be made for the vagaries of an enthusiast; but when possible principles are altogether abandoned, one is not inclined to be over merciful to an offender.

303. The golden age of pointed architecture was from the middle of the 13th to the latter end of the 14th century, and one of the first churches in which it appeared, so as to allow it to be quoted as a fair specimen of the style, is that of Gelnhausen, in Swabia, an edifice which, it may safely be said, rose in the beginning of the 13th century. On the plan it is a Latin cross, terminating in three sides of an octagon at the eastern end, where it is flanked by two octagonal towers with plain buttresses at the angles. There is a similarity in the long narrow windows at the eastern extremity to those of the churches of Constantinople; but they are sharply pointed like the end of a lancet, and, from the circumstance, are universally denominated lancet-headed windows. Over these windows are ornamental semicircular recesses; and again above these is a tier of small columns attached to the wall which support arches of *trefoil* formation. In the wall between the columns *quatrefoil* windows are introduced inscribed in circles, and above the arcade each face of the octagon is pierced with a small window of two apertures, both ending in trefoil heads. Each side is crowned by a rectilinear gable, under whose sloping sides occurs the *nebule* or wavy ornament, bearing some resemblance to small arcades, with their imposts rounded. The octagon is crowned generally by a lofty pyramidal roof, without ornament. The two towers on the flanks are divided horizontally, by means of rectangular panels, into five horizontal parts, each of them at the upper part being decorated with small semicircular corbel-formed ornaments. The faces are crowned by small pediments, and the tower is terminated by a plain pyramidal spire. The central tower of the edifice is octagonal on the plan, containing two tiers of windows; whereof those in the lower tier have some double, others triple, apertures, formed by *mullions*, over which are trefoil heads; whilst those in the upper tier have double apertures with pointed heads. The central opening of the three-light windows in the lower tier rises above those on the sides; but they are enclosed under one semicircular arch. This tower is also crowned with a simple pyramidal spire.

304. The beautiful church at Oppenheim, dedicated to St. Catherine, is, like that just described, a Latin cross on its plan, and consists of a nave and transepts. Its chancel is five sides of an octagon. As in many of the churches of Germany, it has a second chancel for the canons at the western extremity, terminating in three sides of an octagon. The entrances are on the north and south sides of the transepts. From a MS. chronicle of the church, quoted by Möller, it is ascertained that the nave and

eastern chancel were begun in 1262, and finished in 1317. The western chancel was not consecrated till 1439. The total length of the church, including the two chancels, is 268 ft. ; whereof the western chancel, whose breadth is 46 ft., occupies 92 ft. The nave is 102 ft. in length, and its breadth 86, that breadth comprising the two side aisles which are separated from the nave by clustered columns. The transept is 102 ft. long, and 31 ft. broad. In the side aisles are small chapels. In the western front, at the extremity of the nave, are two towers, standing on square bases, each of four stories, and crowned by an octagonal spire. In their three upper stories are round-headed windows, which, where double, are separated by pilasters. The windows of the aisles occupy the whole space between the buttresses, are without mullions, and have pointed arches. The buttresses, whose faces are ornamented with panels, are without pinnacles. The upper windows are surmounted by rectilinear pediments, with crockets and slender pinnacles between them. The doorway of the south transept is with a pointed arch, having one lancet-headed window above. The transept terminates in a gable, within which seven small pediments are placed. Buttresses are placed at the angles of the transepts terminating in pinnacles. Buttresses without pinnacles flank the angles of the hemi-octagon at the east end, whose sides are pierced with lancet-headed apertures. In the western façade is an elegant rose window of twenty small leaves in groups of five. Over the intersection of the transepts with the nave stands an octagonal tower, in each face of which is a pointed window. The centre is covered with a small cupola. On a visit to this beautiful church about four years since, we were pleased to find it under repair, and likely to be preserved.

305. The two churches of Germany whose fame makes it necessary to notice them here are those of Strasburg and Cologne. The first was begun in 1277, by Erwin de Steinbach, and was carried on under various architects till 1439, since which nothing has been done towards its completion. Among the examples of pointed architecture, this is the most stupendous. There is a similarity of style between it and the cathedrals of Paris and Rheims, except that the ornaments are more minute. The plan is a Latin cross, whose eastern end terminates interiorly in a semicircle, but on the exterior in a straight line. The length of the church is 324 ft., that of the transept 150 ft. : the height of the vault of the nave is 98 ft. The nave has one aisle on each side of it. The western façade is in three vertical divisions separated by buttresses. In the central one is the principal portal, and thereover, we believe, the largest rose window in Europe. The portal just mentioned, as well as that on each side, has a rectilinear pediment highly decorated. The sides and soffits of the portals are filled with canopies and statues. The two stories of windows above the ground are pointed; those in the first story having slender bar divisions in front of them, and those above being subdivided into three parts by a species of thin buttresses. On the north side of the façade, being the north-west angle of the edifice, rises the spire, whose height has been so variously represented, that some authors have made it 100 ft. higher than others : we believe the correct height to be 466 ft., being greater than that of any church in Europe. To a certain height the tower is square and solid, being formed by one of the vertical divisions of the western façade. Above the solid part, the tower rises to a certain height octangularly, open on all sides, and flanked by four sets of open spiral staircases, which are continued to the line whence the principal tower rises conically in seven stories or steps, crowned at the summit with a species of lantern. In the interior of this church, near one of the large piers of the transept, is a statue of the architect Erwin, in the attitude of leaning over the balustrades of the upper corridor, and looking at the opposite piers. John Hültz of Cologne succeeded Erwin as architect of the fabric : he continued the tower which we have just described, and which was only finished in 1449.

306. We propose to close our view of the pointed architecture of Germany with some short account of that which, had it been completed, would have been the most magnificent and exquisitely ornamented ecclesiastical edifice the world ever saw, we mean the cathedral at Cologne, whose plan (*fig. 154.*) exhibits a symmetry not surpassed by the buildings of ancient Greece and Rome. A church had been erected on the present site of this cathedral in the time of Charlemagne. This was destroyed by fire in 1248, at which time Conrad filled the archiepiscopal throne of the city. Before fire had destroyed the former cathedral, this prelate had resolved on the erection of a new church, so that in the year following the destruction of the old edifice, measures had been so far taken, that the first stone of the new fabric was laid with great solemnity on the 14th of August, being the eve of the Assumption of the Blessed Virgin. Collections were made throughout Europe for carrying on the works, and the wealth of Cologne itself seems to have favoured the hope that its founder had expressed of their continuation. The misfortunes of the times soon, however, began to banish the flattering expectation, that the works would be continued to the completion of the building. Gerard, who was the architect of the works in 1257, suffered the grief of seeing the archbishops of Cologne dissipate their treasures in unprofitable wars, and ultimately abandoning the city altogether for a residence at Bonn. The works do not, however, appear to have been interrupted, though they proceeded but slowly. On the 27th of September, in the year 1322, seventy-four years after the first

Fig. 154.

PLAN OF COLOGNE CATHEDRAL.

stone had been laid, the choir was consecrated. The works were not long continued with activity, for about 1370, the zeal of the faithful was very much damped by finding that great abuses had crept into the disposal of the funds. The nave and southern tower continued rising, though slowly. Under Thierry de Moers in 1437, the latter had been raised to the third story, and the bells were moved to it. In the beginning of the 16th century, the nave was brought up to the height of the capitals of the aisles, and the

Fig. 155.

SOUTH ELEVATION OF COLOGNE CATHEDRAL.

vaulting of the north aisle was commenced; the northern tower was carried on to the corresponding height; and every thing seemed to indicate a steady prosecution of the work, though the age was fast approaching in which the style was to be forgotten. The windows in the north aisle were decorated, though not in strict accordance with the style, yet with some of the finest specimens of painted glass that Europe can boast, a work executed under the patronage of the archbishop Hermann of Hesse, of the chapter, of the city, and of many noble families who are, by their armorial bearings, recorded in these windows. But with this the progress stopped. The works which remain are at once a monument of the genius which conceived such an edifice, and of the civil discords that prevented its completion. *Fig. 155.* exhibits the south elevation of the cathedral, in which the darker lines show the parts actually executed, and the lighter ones those which remain, alas! still to be developed in matter. If the reader reflect on the dimensions of this church, whose length is upwards of 500 ft., and width with the aisles 280 ft.; the length of whose transepts was 290 ft. and more; that the roofs are more than 200 ft. high, and the towers when finished would have been more than 500 ft. on bases 100 ft. wide; he may easily imagine, that, notwithstanding all the industry and activity of a very large number of workmen, the works of a structure planned on so gigantic a scale, could not proceed otherwise than slowly, especially as the stone is all wrought. The stone of which it is built is from two places on the Rhine, Koenigswinter and Unkel-Bruch, opposite the Seven Mountains, from both of which the transport was facilitated by the water carriage afforded by the Rhine. The foundations of the southern tower are known to be laid, at least, 44 ft. below the surface.

307. The states of Europe ought to contribute towards the completion of this stupendous work, which the aid, liberal as it is, of the King of Prussia, does little more than keep in repair; though at this moment there is a complete staff of architect, clerks of works, masons, &c., constantly employed on the fabric. We subjoin a table of the receipts and expenditure upon it in the ten years from 1824 to 1833 inclusive, by which it will be seen how alive, among the sovereigns of the Continent, the late King of Prussia was to the importance of the arts.

Years.	Royal Grant from the Public Treasury in	Produce from Sale of old Materials.	Amount of Contributions towards the Edifice.	Amount of Collections.	Amount of Presents.	Total Receipts.	Total Expenditure.

308. So that the average yearly expenditure, for the ten years above named, amounts to 2716l. sterling, a sum manifestly little more than necessary for keeping the building in repair, and leaving us without the most distant prospect of its ever being more than preserved. The above table is extracted from the small brochure by M. J. De Noel, published at Cologne in 1835.

309. The cathedral at Ulm (*fig. 156.*) is another of the many celebrated cathedrals of

Germany: it was commenced in 1377, and finished, the tower excepted, in 1478. It is reputed to be the longest church in Germany, being 416 ft. long, 166 ft. wide, and, including the thickness of the vaulting, 141 ft. high. The piety of the citizens of Ulm moved them to the erection of this structure, towards which they would not accept any contribution from foreign princes or cities; neither would they accept any remission of taxes nor indulgences from the pope. The whole height of the tower, had it been finished according to the original design (still in existence), would have been 491 feet. It does not preserve the regularity of form for which the cathedral at Cologne is conspicuous, but the composition of it, as a whole, is exceedingly beautiful. At Ratisbon is another beautiful work, of about

Fig. 156.

ULM CATHEDRAL.

the same period, of which *fig. 157.* is a sketch; but we do not think it necessary to detain the reader with the description of it. At Vienna the cathedral of St. Stephen's exhibits another exquisite example of the style.

*Fig. 157.* RATISHON CATHEDRAL.

310. We have mentioned a few of the churches of France in the Byzantine or Romanesque styles. In the thirteenth century the pointed style there reached its highest excellence. "Every thing," observes Whittington, "seemed to conspire, in the circumstances of the nation and of the world, to produce an interval favourable for the cultivation of the arts; and genius and talents were not wanting to make use of the happy opportunity. The thirteenth century found the French artists, a numerous and protected body, in possession of a new and beautiful style of building; the religious enthusiasm of the times, fanned by the spirit of the Crusades, was at its height, and the throne of France was filled by monarchs equally distinguished by their piety and magnificence." The chronicle of the abbey of Bec in Normandy informs us that Ingelramme, who had been employed on the church of Notre Dame at Rouen, was, in 1212, engaged on the church of this Norman abbey, a great portion whereof he raised in a year and a half, and in which he was succeeded by Waultier de Meulan, who finished the work in less than three years. Little of this building remains, from the circumstance of its having been burnt twice within the century, and renewed in its present form about 1273, by the Abbot de Caniba. At this period the churches of France were rising in every direction. At Rheims, the cathedral (*fig. 158.*) exhibited the elegant lightness of the new style; the body of the cathedral at Lyons was completed; the exquisite cathedral of Amiens (*fig. 159.*) was raised by Robert de Lu-

*Fig. 158.* RHEIMS CATHEDRAL.

*Fig. 159.* AMIENS CATHEDRAL.

zarches and his successors; and, among many other architectural beauties, the Sainte Chapelle of the palace at Paris. Neither must we omit the celebrated Eudes de Montreuil, among whose numerous works, after his return from the East, whither he had accompanied St. Louis, was the church of Notre Dame de Mantes, the boldness of whose vaulting astonished Soufflot and Gabriel in their scientific survey of the French churches, and of which it is related, perhaps fabulously, that when the building was finished, the workmen refused to remove the centering, until Eudes, by sending his nephew to assist them, quieted their apprehensions. The height of the vaulting from the pavement is 96 feet. This Eudes died in 1289, and of his two wives, Mahault, or Maud, attended the queen on her voyage to Egypt and the Holy Land. Another artist, Jousalin de Courvaul, is known to have accompanied the king (St. Louis) to the crusade. The number of ecclesiastical structures in France erected during the reign of St. Louis exceeds all former and subse-

quent example. Besides a great number founded by individuals, the church and abbey of St. Antoine near Paris, those of the Filles Dieu, the Jacobins, the Carmelites, and the Cordeliers du Faubourg St. Marcel, were built by command of the king; and, out of the metropolis, the abbeys of Lis near Melun, of Longchamp near St. Cloud, and St. Mathieu near Rouen; the greater part of the abbey of St. Denis; the Hotels Dieu of Vernon, Pontoise, and Compiègne; the church and abbey of Maubuisson; the church of the nuns of Poissy, and the monastery and church of Royaumont by Pierre de Montereau, are recorded as the monuments of this munificent sovereign. At the latter end of the twelfth, or in the beginning of the thirteenth, century, moreover, sprung up a brotherhood, known by the name of the *Confraternité des Ponts*, founded by St. Benezet, to which belongs the honour of having erected a bridge across the Rhone at Lyons in 1244, and the Pont St. Esprit, another vast structure. The first stone of this was laid with great ceremony in 1265 by Jean de Tianges, prior of the monastery of St. Esprit, and the whole structure, above 3000 feet in length, was completed in 1309. The building of bridges and maintaining of roads at this period may be almost deemed to have been as great an act of piety as the founding of churches; and a religious association for such a purpose affords a proof of the previous barbarism and increasing civilisation of the age.

311. The wars carried by the English into the very heart of France, as well as the factions and divisions of the French nobility, put a stop to the cultivation of the fine arts, and the fine pointed style of this country ceased about the fourteenth century. The two succeeding ones were not distinguished by architectural efforts of excellence equal to those whereof we have been speaking. Before the invasion, however, of Edward III. and in the provinces at a distance from the scene of warfare, the earlier part of the fourteenth century produced some beautiful churches, among which was that of St. Ouen at Rouen, a work celebrated no less for the beauty of its composition than for the remarkable skill and delicacy exhibited in its execution. It was begun under the abbot, Jean Marc d'Argent in 1318, but not finished till near the middle of the following century. Under Charles V., whose valour and policy procured for France a more favourable aspect in the affairs of the country, many buildings of importance were undertaken and completed. The principal edifices, however, of this monarch were of a nature civil and military rather than religious. The Bastille and the castle of Vincennes were finished by him; in the latter whereof he founded, about 1379, a very beautiful chapel, on the model of the Sainte Chapelle at Paris. The Châtelet, the walls of the city near the Porte St. Antoine, the châteaux of St. Germain en Laye, Montargis, and Creil, were constructed by him, as also many improvements and additions at the Louvre. Charles VI. was more interested in preparations for the invasion of England than in the patronage of architecture: he nevertheless caused the erection of the abbey of Bonport and some other edifices.

312. Though in the fourteenth century the style of the thirteenth did not altogether disappear, its character gradually altered, especially in the continuation of the mullion work over the heads of the windows, which, from being ornamented with six foils or roses, were now branched out into the form of leaves; and the compartments of the circular windows in transepts, and at the end of naves, underwent a great change in their composition, often extremely fanciful. The vaultings of the roofs, too, were much more highly decorated. All these alterations took place at nearly the same period, or a short time after, in England, whose prosperity then enabled the artist to carry them to a much higher state of perfection and magnificence, as will hereafter be shown.

313. The fifteenth century was not more favourable to the practice of architecture in France than the fourteenth had been. It produced few buildings, nor was it indeed probable that any of grandeur and importance could have been undertaken and carried on during the constant and sanguinary contests which concluded with the expulsion of the English from its shores, by which the monarchy from its most abject degradation was once more restored to vigour and prosperity. "The architectural taste of this age," says the author whom we have so much quoted, "resembled the contemporary style of England and other countries. Many instances of tracery may be remarked, especially in sepulchral monuments and chapels; but the distracted condition of France afforded little leisure to her inhabitants for works of piety and genius; and prevented them from adding to the sumptuous structures of their ancestors any great example of that superlative beauty or richness which characterise the architecture of England at this period." The time, in fact, had arrived when it was to be superseded altogether by the disposition which soon became universal in Europe for returning to an imitation of the works of the ancients, which, begun by the artists of Italy, was soon carried into every other country where civilisation had a footing.

314. Our notice of pointed architecture in France we shall close with a short notice of the cathedrals of Rheims and Amiens, which, with Mr. Whittington, we are of opinion are two of the finest examples of the style in the world. The former, which was not quite finished till 1440, is in the form of a Latin cross on the plan; its length from east to west is 492 ft., and its breadth, measured to the extremities of the arms of the transepts, is 190 ft. The interior is divided longitudinally into a nave and choir with side aisles.

The width of the transepts is 98 ft., which is equal to that of the body of the church; and the transepts, like the nave and choir, have their side aisles. The western front is composed as usual, with three entrances, the centre one being the largest; the three being crowned with pointed arches and high pediments with their crockets and finials. The buttresses of the front rise between these pediments, terminating in slender pinnacles. Over the centre door is a very magnificent circular window, with radiating mullions, terminated at the circumference by pointed arches. It should also be mentioned that in the head of the doorway is a circular window, and above that (partly hidden by the pediment of the doorway on the outside) is a tier of small windows, like niches, over which is the great window just mentioned. Over each side portal rises a square tower, decorated in the first story with windows, and in the second with a canopy which extends horizontally throughout the façade; the height of the towers being 270 ft. from the ground. The portals are of the most superb description, the soffits of the arches being masses of canopy work, exquisitely formed and elaborately finished. This work was planned and begun in 1215, at which time the pointed architecture of England was by no means so advanced towards perfection as it was on the Continent, the cathedral of Salisbury having been commenced 15 years later.

315. The cathedral of Amiens has always been the admiration of travellers, and "claims," says Whittington, "our attention, as it seems to throw a very strong light on the history of that style, which has so long been, and probably will continue to be, distinguished by the contemptuous epithet [Gothic] it at present bears." The date of the cathedral of Amiens having been correctly ascertained, and nearly coinciding with that of Salisbury, it is fair to compare the contemporary styles from these two examples. They were begun in the same year 1220, and the original plans in both were carried through without mixture of the styles that succeeded before their completion. We entirely agree with Whittington, that of the two, Amiens is in a more perfect and advanced state of art than Salisbury, and that the French were before us in adding to the simple beauties of the former period many graces which we did not adopt till the latter. In England the prominent feature of the thirteenth century was the highly pointed arch, struck from two centres, and including an equilateral triangle from the springing to the crown or apex of the arch; and another, as Bentham (*Hist. of Ely*) well observes, is the employment of Purbeck marble pillars, very slender, and encompassed by marble shafts, a little detached, and a profusion of small columns of the same stone in the ornamental parts of the building. These peculiarities are found in Amiens, the arches of whose aisles resemble those of Salisbury and Westminster, as do the pillars. The vaulting, moreover, is like that of Salisbury. In plan, proportion, and ornament, however, the general character of the building differs very materially. As respects the first, the aisles to the transepts, the double ones on each side of the choir whose end is so beautifully terminated by a semicircular colonnade, are differences from Salisbury; the number of columns, too, exceeds that used in our churches of the same date, and produces an infinitely richer effect. The dissimilarity is continued in the proportions of the whole cathedral, and especially in the height in relation to the width, that of the pillars to the width of the arches, and in many other details. It is nevertheless in the ornamental part that the chief difference exists, and most particularly in the hosts of saints, prophets, martyrs, and angels, which line the doors, cover the walls, and cluster round the pinnacles. There is nothing in the church of Salisbury which approaches this. We have not, however, space to pursue the subject, and shall therefore close it with a comparison of the respective dimensions of the French with the English church.

Direction of Dimensions.	Salisbury.	Amiens.
Length from east to west	Feet. 452	Feet. 444
— from the west door to the choir	246	235

316. A more amusing instance of the value of the investigation of architectural subjects by literary men cannot be referred to, than that of Gray the poet having compared the

cathedral of Amiens with that of Canterbury; between which structures there is not the smallest point of resemblance, except in their both being built for religious purposes. The church at Amiens suffered during the Revolution considerably less than any of the other French churches of importance.

317. In closing the view of the pointed architecture of France, it may be useful to add a list of a few of the cathedral churches in that country, with their dates and architects, before the end of the thirteenth century.

Church.	Date.	Architects.
Chartres - - -	1029	Fulber.
Charité sur Loire - -	1056	Gerard.
Clugny - - -	1070	Hugues.
Notre Dame, Paris - -	1161	Mauricede Sully. Finished by Jean de Ravy, 1257; and Pierre de Montereau, 1270.
Bec - - -	1212	Ingelramme. Finished by Walter de Meulan, 1216.
Rheims Cathedral - -	1215	Hugues Libergier. Completed by Robert de Coucy.
Rouen ditto - -	1216	Ingelramme. Finished by W. de Meulan.
Amiens ditto - -	1220	Robert de Luzarches.
Sainte Chapelle de Paris -	1245	Pierre de Montereau.
Lyons - - -	1270	Robert de Luzarches.
Notre Dame de Mantes -	1280	Eudes de Montreuil.
St. Germain des Prés, Paris		
Chapel of our Lady - -	1288	Finished. Foundations laid by Pierre de Montereau in 1227.

318. The pointed arch is found throughout Italy. We do not believe there was any great difference in the times of its introduction into the various countries of Europe; the earliest example in Italy is believed to be the church of San Francesco at Assisi. The cathedrals at Orvieto and Sienna, and some beautiful examples at Verona, Vicenza, and Viterbo, show that it prevailed in Italy with many modifications. It is not necessary to pursue its history merely with reference to this country; and we shall therefore content ourselves with a short account of the principal structure in it which exhibits the style. The cathedral at Milan (*fig. 160.*) was begun in 1336, and finished in 1387. It is constructed of white marble. The plan is a Latin cross, the transepts extending but little beyond the walls of the church. From west to east its length is 490 ft., and its extreme breadth 295. Each extremity of the western front has a small square tower 43 ft. wide in each direction. The length of the nave is 279 ft., and its width 197 ft. It is divided longitudinally into a central and four side aisles, and lighted by five cupolas. The transepts are also divided into a central and two side aisles, in the direction of their length. The eastern end of the church is terminated by three sides of an octagon. The architecture of the doors and windows of the western front is of Italian or Roman style, and was executed at a late period; but the whole of it ends upwards in a great gable or pediment, taking in the extreme width of the elevation. Its apex is 170 ft. from the pavement, and the sloping sides are ornamented with tabernacle work. The central pinnacles are 195 ft. high, and are horizontally divided into six stories, which, as they rise, gradually diminish in breadth, the last forming a small pyramidal spire. The faces of the towers are encrusted with tabernacle work, and canopied statues standing on corbels. In the third story from the bottom a painted window, separated into three divisions by mullions, is introduced. The rest of the façade is vertically divided by buttresses into five parts, the buttresses being ornamented with statues on corbels, and terminating in lofty pinnacles. The central tower, which stands over the intersection of the transepts with the nave, rises to the height of 400 ft., being in general form similar to those which appear in the western façade. All the towers and pinnacles are crowned with statues. The roof is covered entirely with

Fig. 160. CATHEDRAL AT MILAN.

K

blocks of marble, which are fitted together with such exactness that they are like one piece. The principal architect of the fabric was Zamodia, a German. It must be here remarked, that the interior of the cathedral of Milan, which is of the close of the 14th century, is in the same character of style as that which prevailed in France and Germany during the era. Kerrieh (MSS. Brit. Mus.) has very truly said, that "we have nothing which might authorise a strict comparison with the cathedral at Milan, as to the immensity of the work, or the astonishing and endless labour which has been expended upon it. Without ascending the roof, no idea can be formed of the vast profusion of elegantly carved ornaments, the Gothic work, or the astonishing number of statues and alto-relievos which are found there; some very small, others of a gigantic size—generally speaking good. They possess, of course, different degrees of merit, as having been made in different ages. There is a singular application of them, which is seen I believe no where else—they stand upon the very summit of pinnacles and finials. The *louvre* in the centre of the church is very large, and of grand effect, but is disfigured by a wooden spire. The flying arches are literally feathered with crockets." We subjoin a table, with the dates and architects, of some of the principal cathedrals of Italy, in which the pointed arch is found:—

Place.	Date.	Architect or Founder.
Genoa - - -	1125	Founded by Martino Doria.
Messina - - -	1180	Founded by Ruggiero, Count of Sicily, in 1100.
Palermo, Monte Reale	1185	
Benevento - - -	1198	
Padua - - -	1231	Bishop Ruggiero, nephew of the last. Nicola da Pisa.
Arezzo - - -	{ 1240 to } 1260	Lapo, a German.
Orvieto - - -	1290	Lorenzo Maitani.
Naples - - -	1260	Giovanni da Pisa.
Sienna - - -	1338	Lapo da Siena.
Milan - - -	1387	Zamodia.

319. In the church of San Lorenzo at Genoa appears a strange mixture of styles: the nave is separated from the aisles by Corinthian columns, connected by pointed arches, and bearing an horizontal entablature, above which reigns an arcade, whose supports are alternately columns and piers. The internal appearance of the church is singular, from the courses of the masonry being alternately of white and black marble. The cathedral at Palermo seems to indicate a Moresque as well as pointed style, and is a curious example, whereof the representations will convey a much better idea than a description here, which, however, we should not decline, if the subject had not already been placed fully before the reader. Every example within the range of Moorish dominion unites to prove the hypothesis on which we have relied.

320. In the splendid cathedrals of Spain a style prevails wherein we find almost an amalgamation of Saracenic with that which prevailed in Europe after the introduction of the pointed arch. That at Seville, which was raised near the end of the 13th century, is 420 ft. long, 273 ft. broad, and 126 ft. high. The choir is in the centre of the church; and the interior, though as respects the plan unintelligibly split into small parts, possesses features of extraordinary beauty. The celebrated *Giralda*, or bell-tower, seated at one angle of it, is perhaps the most picturesquely designed campanile in Europe. The lower part, being 200 of the 300 ft. in height to which it rises, was built by the Moors towards the end of the 10th or beginning of the 11th century. It contains a staircase of so easy ascent that two horsemen may mount abreast more than half way towards its summit. The cathedral at Burgos is another exquisite specimen of the art in Spain, and has always been considered among the best examples of Europe in the pointed style, which on the Continent was always more exuberant in ornament than in this country. It has two towers ending in spires at its west end; and from the central part of the edifice a square tower of great beauty rises, whose sides are ornamented with eight pinnacles. The parts of this cathedral are elaborate, and finished with extraordinary attention to detail. At the eastern end an octagonal building is seated, crowned with a pyramidal roof. This church is said to have been executed on the designs of John and Simon of Cologne, after 1442.

321. Portugal produces a number of examples of the pointed style, one whereof, the church of Batalha (*fig. 161.*), is of the most magnificent description. We always differ with reluctance from Dr. Milner, and especially in the case of the Batalha, which he considers only a pleasing variety of Gothic architecture, and not to be put in competition with many of the contemporary buildings in other parts of Europe on the general principles of sublimity and beauty. Our opinion is directly the reverse. The church at Batalha is 416 ft. in length, and 541 ft. from north to south including the monastery. Its plan is that of a Latin cross, and the

interior is divided by columns into a nave, with an aisle on each side, the eastern end terminating in three sides of an octagon. The aisles are equal in height to the nave; the vaults of both being groined, and springing from clustered pillars. The side walls have two tiers of pointed windows; those of the lower tier having their radii of curvature equal to two thirds of their span, and those above equal to three fourths of it. The windows are splayed towards the interior, their sides being ornamented with a number of small columns, wherefrom stems are produced which meet at the top of the aperture. Each window is in three divisions, separated by upright mullions, and ending in trefoil heads. Six quatrefoils are introduced between the tops of the last and the intrados of the arch. In the chancel the windows are narrow in proportion to their height, and terminate in lancet heads. The main walls are crowned by pierced battlements with pinnacles. The tower is octagonal on the plan, and receives a small open-worked pyramidal spire. Attached to this church, marble, is the extremely beautiful mausoleum of King John (fig. 162.), whose pierced

Fig. 161. CHURCH OF BATALHA.

which is constructed entirely of white King John (fig. 162.), whose pierced

spire reminds one of those in Normandy and Germany, and gives another instance of the universal consent of the age in carrying pointed architecture to the utmost limits of decoration; a desire which, connected with the changes of the times, led to its abandonment very soon after it seems to have reached the acmé of perfection.

Fig. 162. MAUSOLEUM OF KING JOHN.

the sea on the shores of a continent, on the taste of Europe, and not felt immediately, but in, as it were, the distance of the original wave from its destination; for it is certain that the British Isles were behind the rest of Europe in its adoption. And this we think another satisfactory reason for assigning the origin of the pointed arch to the East.

## SECT. XVI.

### ITALIAN ARCHITECTURE.

323. The period to which we have advanced in the architecture of Italy is seen in the last section: we have now to commence a new era in the art, which, dawning in Florence, soon spread its meridian light over Italy and the rest of Europe. The French have well applied the term *renaissance* to its commencement. It is with us denominated that of the *revival* of the arts. The Florentines had at an early period, according to Villani, determined to erect in their city a monument which should surpass all that had before appeared; and in 1268 Arnolfo di Lapo, according to Vasari, but according to Molini Arnolfo di Cambio da Colle, to whom they confided its execution, had so prepared his plans that its foundations were in that year laid, on the day of the feast of the Nativity, and the name of Sta. Maria del Fiore was then given to it. This edifice, though com-

menced long before the revival of the arts, seems to have been conceived by its architect in an original style, forming, as it were, a mean between the pointed and ancient style. It is therefore one of particular interest and instruction in the history of architecture, and one wherein we find a construction in which preparation was made for changing the style then prevalent into one sanctioned by the ancient principles of the art; and it is certain that it was the first which gave the hint for the grandest monuments of modern architecture. *Fig. 163.* shows the plan, and *fig. 164.* the half section and half elevation of it. The walls

Fig. 163.

PLAN OF SANTA MARIA DEL FIORE AT FLORENCE.

are almost entirely cased with marble. The whole length of it is 454 feet; from the pavement to the summit of the cross is nearly 387 feet; the transept is nearly 334 feet long; the height of the nave 153 feet, and that of the sides aisles  $96\frac{1}{2}$ . Between the period of the beginning of the edifice and that in which its completion was entrusted to Brunelleschi, many architects of great talent had been employed in carrying on the works: among whom we find the names of Giotto; Taddeo Gaddi; Andrea Orgagna, a man of extraordinary powers, as his Loggia in the Piazza at Florence amply testifies; and Filippo di Lorenzo. The revival of architecture is so connected with the life of Brunelleschi, that a few passages in the latter will assist us in giving information on the former. He was born in 1377, and by his father Lippo Lippi, a notary of Florence, was intended to succeed him in his own profession; but the inclination of the youth bent towards the arts, and the parent with reluctance yielded to it, and placed him with a goldsmith, an occupation then so connected with sculpture that the greatest artists of the time applied themselves to the chasing and casting ornaments in the precious metals. Brunelleschi, though skilful as a sculptor, had many rivals; and ambitious, it would seem, to be the first in the art to which he should apply his powers, determined to devote himself entirely to architecture, in which the field was then unoccupied. In company with Donatello he therefore visited Rome, and applied himself with ardour to the study of the ruins in the Eternal City; and what was said by Constantius on seeing the forum of Trajan, as related by Ammianus Marcellinus, might be truly said of Brunelleschi:—"Hærebat attonitus per giganteos Marcellinus, circumferens mentem, nec relatu affabilis, nec rursus mortalibus appetendus." It was in Rome, though he never communicated his thoughts on the subject to his friend Donatello, that he began to meditate upon the scheme of uniting by a grand cupola the four naves of the Duomo at Florence; a project which till his time was considered almost impossible. During his residence, also, he traced and settled in his mind the proportions of the orders of architecture from the classic examples which the city afforded. Here it was that he studied the science of construction as practised by the ancients: from them he learnt that perfect accordance which always exists between what is useful and what is beautiful, both of which are reciprocally subordinate to each other. Here he discovered the principles of that nice equilibrium, equally requisite for the beauty no less than for the solidity of an edifice. In short, throughout he found "sermons in stones;" and, having thus qualified himself for the great work he sought, returned to Florence in 1407. In this year the citizens convoked an assembly of architects and engineers to deliberate upon some plan for finishing the Duomo, as Sta. M. del Fiore is usually called; a name given to the cathedrals of the cities of Italy. To this assembly Brunelleschi was invited, and gave his advice for raising the base drum or attic story upon which the cupola should be placed. It is not important here to detail the jealousies of rivals which impeded his project; nor, when the

Fig. 164.

HALF ELEVATION AND HALF SECTION OF SANTA MARIA DEL FIORE.

commission was at length confided to him, the disgraceful assignment to him of Lorenzo Ghiberti as a colleague, whose incapacity for such a task our architect soon made manifest. Suffice it to say, that before his death he had the satisfaction to see the cupola finished, with the exception of the exterior of the drum under the cupola; for whose decoration, as well as for the lantern with which he proposed to crown the edifice, he left designs, which, however, were lost. One of the directions he left on his death particularly insisted upon the necessity of following the model he had prepared for the lantern, and that it was essential that it should be constructed of large blocks of marble so as to prevent the cupola from opening; an advice which experience has since proved in other cases to be far from sound. This cupola is octagonal on the plan, as will be seen by reference to the figures, and is 138 feet 6 inches in diameter, and from the cornice of the drum to the eye of the dome of the height of 133 feet 3 inches. Before it nothing had appeared with which it could be fairly put in comparison. The domes of St. Mark and that at Pisa are far below it in grandeur and simplicity of construction. In size it only yields to St. Peter's at Rome, for which it is probable it served as a model to Michael Angelo; for in both, the inner and outer cupolas are connected in one arch at their springing. It is moreover well known that Buonarroti's admiration of it was so great that he used to say that to imitate it was indeed difficult, to surpass it impossible. Vasari's testimony of it shall close our account of this magnificent structure: — "Se puo dir certo che gli antichi, non andarono mai tanto alto con lor fabbriche, ne si messono a un risico tanto grande, che eglino volessino combattere col cielo, come par veramente ch'ella combatta, veggendosi ella estollere in tan' altezza che i monti intorno a Fiorenza paiono simili a lei. E nel vero pare, che il ciel ne abbia invidia poiche di continuo le saette tutto il giorno la percuotono." It might be supposed that such a work was sufficient to occupy the whole of Brunelleschi's time; not so: the Duke Filippo Maria engaged him on the fortifications at Milan, besides which

he was employed on several other military works; a proof of the great diversity of talent he possessed. It is, therefore, from the extensive employ he enjoyed, not only in Florence, but in many other parts of Italy, quite certain that he infused a new taste into its buildings, and that he is justly entitled to the title of the Restorer of Architecture in Europe. He died, and was buried in the church he had raised in 1444. He left a number of scholars, among whom Luca Fancelli and Michelozzo were perhaps the ablest. These pupils spread throughout Italy the effects of the vast change that had been thus begun; a taste for architecture was excited; its true principles became known; and in a short space of time, as if the matter had been one of arrangement between them, the illustrious house of Medici, the dukes of Milan, and the princes and nobility of the country contended who should most patronise its professors. The learned began to expound to artists the books of Vitruvius, the only writer among the ancients whose works on that subject have come down to us.

324. Leo Battista Alberti, of the ancient and illustrious family of the Alberti of Florence, succeeded Brunelleschi in carrying on the great change of which we have been speaking, and was, indeed, a great contributor to the art, not only by his literary labours on architecture, in which he displays profound erudition, knowledge of construction, and an intimate acquaintance with the works of the ancients, but also by the distribution, elegance, grace, and variety, which his designs exhibit. His book, *De Re Edificatoriâ*, is the foundation of all that has been since written on the art, and deserves careful perusal by every one who studies for the purpose of practice. We shall here present a short account of it, which, in imitation of Vitruvius, he divided into ten books.

325. The *first* book treats on the origin and utility of architecture; the choice of the soil and situation for placing buildings; the preparation, measurement, and suitable division according to their nature, of the edifices to be erected; of columns and pilasters; of the different kinds of roofs, doors, and windows, their number and size; of the different sorts of staircases and their landings; of the sewage or drains, and of suitable situations for them respectively. In the *second* book the subjects are, the choice of materials; the precautions to be taken before beginning a building; the models, of whatever description, that should be made; the choice of workmen; the trees fit for use, and the season in which they should be felled; the methods for preventing rot, and susceptibility of fire; of stone in its varieties; the different sorts of bricks, tiles, lime, sand, and mortar. The *third* book treats of construction; foundations according to the varieties of soil; encroachments; the carrying up and bond of masonry; rough and rubble work; on the different sorts of masonry; on the inlaying and facing of walls; on beams, joists, and the method of strengthening them; on floors, arches, and vaults; the covering of roofs, pavements, and the season for beginning and completing certain works. The *fourth* book is confined to the philosophy of the art, showing the causes which influence mankind in the adoption of modes of building according to the climate, the soil, and the habits or government of a people. It, however, treats of the proper position of a city; of the size to be given to it; of the form of the walls; of the customs and ceremonies of the ancients as applied to this point; of fortifications, bastions or towers, gates and ramparts; bridges, both of timber and stone; sewers, ports, harbours, and squares requisite in a city. The *fifth* book contains instructions for the erection of palaces for peaceable, and castles for absolute princes; for the houses required by a republic; large and small religious edifices; academies, public schools, hospitals, and palaces for senators. In it are given some hints on military and naval architecture, on farm buildings, and country houses. In the *sixth* book Alberti treats on architectural ornament, columns, and the method of adjusting their proportions. After some observations on the principles of beauty, on taste, and on the mode of improving it, he enters shortly on the history of architecture. These are followed by several chapters on the doctrine of mechanics, machines, the method of raising and working columns, polishing them, imitations in stucco and incrustation in thin layers, and matters of that nature. The *seventh* book continues the discussion on ornaments in architecture, but chiefly in respect of columns, showing the edifices in which the use of them is suitable; and, in imitation of Vitruvius in his directions relative to temples, our author dilates on buildings for ecclesiastical purposes. He shows what sorts of columns and pilasters are best suited to them, how far the employment of statues is proper, and how they should be sculptured. The *eighth* book is on roads and their decorations, tombs, pyramids, columns, altars, epitaphs, &c. In it he turns to the subjects of streets, cities, ornaments appropriate to gates, ports, arches, bridges, crossways, markets, public squares, walks, porticoes, theatres, amphitheatres, circi, libraries, colleges, baths, &c.; and the style in which public buildings should be constructed and decorated. The *ninth* book is a continuation of the preceding one; but in this he speaks in addition of the appropriate decoration of royal palaces, and of the ornaments respectively suitable to city and country dwellings, and of the paintings and sculpture that should be employed in them. In the *tenth* and last book the principal subject is the finding a supply of water for buildings both in town and country, and it goes with some useful hints on the aid of architecture to domestic economy. This truly great man constructed many works in different cities of Italy, some of which still remain to

attest his skill. We are not to examine them with the eye of an architect flourishing even half a century later, though under that category they do him honour, but with the eye of an artist of his own day, and we shall then find our veneration for his memory cannot be too strongly expressed. In Florence he finished the Ruccellai palace, and built the choir of the Annunziata. At Mantua he built a church of singular beauty, consisting of a simple nave, crowned with a vault decorated with *caissons*, which rivals the works of the ancients. The additions he made to the church of St. Francesco at Rimini, a pointed church, though not in the same style, because it then came into disrepute, show an extraordinary aptitude for overcoming the most difficult and repulsive subjects with which an architect has to deal, and that work alone would stamp him as a man of genius. On his other acquirements it is not within our province to dwell; we shall merely sum them up by saying that he was poet, painter, sculptor, philosopher, mathematician, and antiquary. Such was Alberti, in whom was concentrated more refinement and learning than have hardly since appeared in a single individual of our species. The time of his death is not accurately known; some place it at the end of the fifteenth, and others at the beginning of the sixteenth century.

326. About the time that Alberti was engaged on the practice and literature of the art, a very extraordinary volume, written by a member of the Colonna family, was published by Aldus, at Venice, in 1499, folio. Its title is as follows:—*Polyphili Hypnerotomachia; opus italicè linguâ conscriptum; ubi humana omnia non nisi somnium esse docet*. This work deserves to be better known than we fear its rarity will ever permit. With the singularity of the plan, it unites the advantage of placing before the reader many elevated and elegant ideas, and, under the veil of a fable, of inculcating precepts of the greatest utility to artists and those that love the art. The testimony of Felibien in favour of this work runs so favourably, that we must transcribe it:—"Sans préjudice," says that author, "du grand profit qu'on peut tirer de la lecture de Vitruve, et de l'étude qu'on doit faire de ses principes et de ses règles, il ne faut pas moins examiner les tableaux curieux de plusieurs superbes édifices, monumens ou jardins, que l'imagination riante et féconde de l'auteur du *Songe* a mis sous les yeux de ses lecteurs." When it is recollected that the manuscripts of Vitruvius were extremely rare, and that when Colonna wrote (1467) that author had not been translated,—when we reflect that in his descriptions he hears edifices as magnificent and regular as those which Vitruvius presents to us, we cannot withhold our surprise at the genius and penetration of the author. With him architecture appears in all her majesty. Pyramids, obelisks, mausolea, colossal statues, circi, hippodromi, amphitheatres, temples, aqueducts, baths, fountains, noble palaces, delicious gardens, all in the purest taste and of the most perfect proportion, attend in her train, and administer to the pomp with which the author attires her. With him all these ideal productions of the art were not merely the result of an ardent imagination, but were the fruit of an intimate acquaintance with its rules, which he explains to his reader, and inspires him at the same time with a taste for the subject of his pages. He often breaks out against the gross ignorance of the architects of his day, and endeavours to inculcate in them the sound principles of the art. He demonstrates that it is not enough that an edifice possesses stability and solidity, but that it must be impressed with a character suitable to the purpose for which it is destined; that it is not enough that it be well decorated, but that the ornaments used arise from necessity, or at the least from utility. Architecture thus treated in fiction was much more pleasantly studied than it would have been by mere application to the dry rules of Vitruvius. The impression made by the work was increased by the poetic glow with which the precepts were delivered; the allegories it contained warmed the imaginations of a people easily excited, and Italy soon saw realised what Polyphilus had seen in a dream. This work is decorated with wood engravings of singular beauty, in which the details and accessories are strictly classical; it is written with great spirit and elegance, and we are not amazed at the magical effect which, with the accompaniment of Alberti's book above mentioned, it every where produced.

327. The Italian school, which ultimately appropriated and adapted the ancient Roman orders and their details to comparatively modern habits, was for a long while engrafted on or amalgamated with what is called Gothic. We here (*fig. 165.*) place before the reader an instance of this, in the celebrated Loggia at Florence, designed by Orgagna. The same feeling appears, indeed, in what Brunelleschi did in his Duomo, and in many other buildings in Florence, in Pisa, Sienna, and other cities. Brunelleschi doubtless made a strong effort to emancipate himself altogether from the mixture of two discordant styles, and in some measure succeeded. Still there continued, as is evident in the Ricardi, Strozzi, and other palaces in Florence, a lingering love for the mixture, which the architects had great apparent difficulty in shaking off. It is, however, extraordinary that with all this lingering love for the ancient style, in which there was much littleness, when the architects of this period came to the crowning members of their edifices, they placed on them such massive and finely composed cornices that the other parts are quite lost; and in this member it is evident they were influenced by those feelings of unity and breadth that gave so much value to the best works of the ancients.

Fig. 165.

LOGGIA OF ORGAGNA.

328. The revival of the arts in Italy was vastly assisted by the commerce and riches of the country; and with the decay of that commerce, nearly 300 years afterwards, their palmy days were no more: from that time they have never thriven in the country that gave them birth. It is our intention, in this view of Italian architecture, to consider it under the three schools which reigned in Italy — 1. The Florentine; 2. The Roman; 3. The Venetian.

329. 1. *Florentine School.* — Climate and the habits of a people are the principal agents in creating real style in architecture; but these are in a great measure controlled, or it is perhaps more correct to say modified, by the materials which a country supplies. Often, indeed, these latter restrict the architect, and influence the lightness or massiveness of the style he adopts. The quarries of Tuscany furnish very large blocks of stone, lying so close to the surface that they are without other difficulty than that of carriage obtained, and removed to the spots where they are wanted. This is probably a circumstance which will account for the solidity, monotony, and solemnity which are such commanding features in the Florentine school; and which, if we may judge from the colossal ruins still existing, similarly prevailed in the buildings of ancient Etruria. In later times another cause contributed to the continuation of the practice, and that was the necessity of affording places of defence for the upper ranks of society in a state where insurrection continually occurred. Thus the palaces of the Medici, of the Pitti, of the Strozzi, and of other families, served almost equally for fortresses as for palaces. The style seems to have interdicted the use of columns in the façades, and on this account the stupendous cornices that were used seem actually necessary for the purpose of imparting grandeur to the composition. In the best and most celebrated examples of their palaces, such as the Strozzi, Pandolfini, and others in Florence, and the Piccolomini palace at Sienna, the cornices are proportioned to the whole height of the building considered as an order, notwithstanding the horizontal subdivisions and small interposed cornices that are practised between the base and the crowning member. The

courts of these palaces are usually surrounded by columns or arcades, and their interior is scarcely ever indicated by the external distribution. From among the extraordinary palaces with which Florence abounds, we place before the reader the exquisite façade of the Pandolfini palace, the design whereof (*fig. 166.*) is attributed to the divine Raffaello d'Urbino.

\* Fig. 166.

PANDOLFINI PALACE.

in it almost all the requisites of street architecture are displayed. It is an example wherein the principles of that style are so admirably developed, as to induce us to recommend it, in conjunction with the façade of the Farnese palace hereafter given, to the elaborate study of the young architect.

330. Without further allusion to the double cupola of the Duomo, already noticed, the first of its species, and the prototype of that of St. Peter's at Rome afterwards reared by Michael Angelo, the principles and character of the Florentine school are not so manifest in its churches as in its palaces. These nevertheless possess great interest; for they were the bases on which those of the Roman school were formed, as well as of those examples which, with different degrees of purity, were afterwards erected in many of the capitals of Europe. Besides the plan of the Duomo, those of St. Michele, Sta. Maddelina, St. Pancrazio, St. Lorenzo, and St. Spirito, are the key to all excellence in modern art, as respects real church architecture. It is unfortunate that of this school few of the churches have been finished, so that their façades are generally imperfect. The interior was properly, with them, a matter to be first considered and brought to perfection.

331. Amongst the many extraordinary architects of the Florentine school, whereof a list will hereafter be given, was Bartolomeo Ammanati, whose bridge, "*della Santissima Trinità*," sufficiently proves that the greatness of the Florentine school does not alone depend on its palaces and churches. This, one of the most beautiful examples, as well for design as constructive science, in which was obtained for the waters of the Arno a maximum of waterway, combined with a beauty of form inappreciable through graphic means, still strides the river of Florence, to attest the consummate skill of Ammanati. The bridge in question consists of three arches: the middle one is 96 ft. span, and each of the others 86 ft.; the width of the piers is 26 ft. 9 in., and the breadth of the bridge between the parapets is 33 ft. The arches are very slightly pointed, the cusp being hidden by the rams' heads sculptured on the keystones; their rise above the springing is very little, hence they have been mistaken by some writers for cycloidal arches. Alfonso and Giulio Parigi, who assisted in constructing the work, left an account of the mode in which it was carried on, and the manuscript is still preserved in the Florentine Library. More recently, a description of this bridge has been published by Ferroni, under the title of "*Della vera Curva degli Archi del Ponte della Santissima Trinità di Firenze*." The Pitti palace had been begun in the time of Brunelleschi, in 1435, for Luca Pitti, a wealthy citizen of Florence. Remaining long unfinished, it was at last sold to Eleonora, wife of Cosmo I., who purchased the adjoining ground, and planted the Boboli Gardens. About the middle of the 16th century, Nicolo Bracciani, surnamed Tribolo, made designs for finishing the building; and was succeeded by Bernardo Buontalenti. After him came our Ammanati, who left other designs for finishing, which was accomplished by Alfonso and Giulio Parigi. It is now the residence of the grand duke, and has served as a model for imitation to many modern architects, though there is in it much to condemn. The details, however, and proportions of the orders used in it by Ammanati, are very beautiful. This architect died in 1586, at the age of seventy-five. He was a pupil of Baccio Bandinelli, and during his life composed a large work, entitled *La Città*, which contained designs for all the fabrics belonging to a regular and well-arranged city, beginning with the gates, then proceeding to the palaces of the prince and magistrates, the churches, the fountains, the squares, the loggia for the

merchants, the bridges, theatres, &c. This work appears to have been lost, the last possessor of it known having been the prince Ferdinand of Tuscany. Though in the higher refinement of finished details the Florentine school did not reach the extreme elegance of the Roman and Venetian schools, yet for bold imposing masses of architecture we think no city presents such a collection of highly picturesque architectural examples as Florence. The Pitti palace indeed, just mentioned, is more imposing by its broad parts than almost any other building with which we are acquainted, though it becomes poor when translated into French, as at the Luxembourg.

332. So late as 1454, we find in the Strozzi and other palaces semicircular-headed windows, wherein are half columns at the sides, and a column in the middle, resembling those in the Byzantine or Romanesque edifices. The two apertures thus formed are crowned by semicircular heads, which are circumscribed by the outer semicircle, and the spandrel formed by the three curves is occupied by a patera.

333. The period of the Florentine school, which must be taken as commencing with Brunelleschi, includes the names of Michelozzo, Leo Battista Alberti, Pollaiuolo (who obtained the soubriquet of Chronaca, from his constant recital of his travels), the architect of the Strozzi palace, Raffaele Sanzio, Benedetto da Majano, Baccio d'Agnolo, Baccio Bandinelli, Buontalenti, Ammanati, and others: it extends from A. D. 1400 to A. D. 1600. The works of Michael Angelo, though a Florentine, do not belong to this school; neither do those of San Gallo and some others, who have been improperly classed as Florentine architects.

334. 2. *Roman School.*—Though the city of Rome, during the period of the rise and progress of the Roman school of architecture, was not altogether free from insurrectionary troubles, its palatial style is far less massive than that of Florence. None of its buildings present the fortress-like appearance of those in the last-named city. Indeed, the Roman palaces, from their grace and lightness, indicate, on the part of the people, habits of a much more pacific nature, and an advancing state of the art, arising from a more intimate acquaintance with the models of antiquity which were on every side. The introduction of columns becomes a favourite and pleasing feature, and great care and study appear to have been constantly bestowed on the façades of their buildings; so much so, indeed, in many, that they are but masks to indifferent interiors. In them the entrance becomes a principal object; and though in a great number of cases the abuses which enter into its composition are manifold, yet the general effect is usually successful. The courts in these palaces are most frequently surrounded with arcades, whence a staircase of considerable dimensions leads to the sala or principal room of the palace. The general character is that of grandeur, but devoid altogether of the severity which so strongly marks the Florentine school. The noblest example of a palace in the world is that of the Farnese family at Rome, to which we shall afterwards have occasion to return.

335. Bramante, born in 1444 at some place, but which is still in doubt, in the duchy of Urbino, must be considered the founder of the Roman school. Though educated as a painter under Fra Bartolomeo, and likely to have ranked in that occupation as a master of no ordinary powers, his great love of architecture induced him at an early period to quit painting as a profession. In Lombardy he wandered from city to city for the purpose of obtaining employment as an architect, but there is no evidence that his exertions in that part of Italy were rewarded with great success. The dry style which afterwards characterised his works has been said to have had its origin in his protracted stay at Milan, while the works of the Duomo were carrying on there under Bernardino di Trevi, a builder of such skill as to have gained the esteem of Leonardo da Vinci. Be this as it may, it was in this city his determination to follow our art became irrevocable. From Milan he went straightway to Rome; where, however, he was obliged to make himself known by some works in his first profession of a painter in the church of St. Giovanni Laterano. Naturally of hospitable and social disposition, and a lover of expense and luxury, so intense was his ardour to become great in the art he adopted that he refrained from all society, holding commerce only with the monuments of antiquity by which he was surrounded, studying with the utmost diligence, and drawing them for his future application of the principles upon which they were founded. He even extended his researches to Naples, losing no opportunity of noting all the ruins from which instruction in his art could be drawn. Orsafia (Cardinal of Naples), who had remarked his zeal, gave him his first commission in Rome, which was the construction of the cloister of the Convent della Pace; and this, from the intelligence and speed with which he executed the task, brought him at once into repute. At this period Rome could boast but of few architects, and those that were established there were of small account. The Florentine school seems to have sprung in the most decided manner from the habits of the people and the massiveness of their materials, modified by some knowledge of the buildings of the ancients; that of Rome seems to have been founded upon the principle of making the ancient architecture of Rome suit the more modern habits of a very different people, though living on the same spot. To explain more immediately our meaning, we cite the small circular chapel

of St. Pietro in Montorio, wherein we find a jump at once in the adaptation of the circular peripteral temple of the Romans to the purpose of Christian ceremonies. And again, it is impossible to look at the Palazzo della Cancelleria without being struck by the basement and two orders, which would be suggested by a contemplation of the Coliseum, though afterwards the Roman architects had the good sense to see that the orders of architecture placed against the walls of a building where the use was not required by the interior distribution was a tasteless and useless application of them. The architect of the Palazzo Farnese only uses them for the decorations of his windows. In this respect we hope good sense is once more returning to this country; and that the absurd practice in almost every case of calling in the orders to aid the effect of a façade, will be abandoned for the better plan of obtaining an imposing effect from the simplicity and arrangement of the necessary parts. We must, however, return to Bramante, whose other employment we pass over to come to his great work,—one which, after the continued labour upon it of his successor Michael Angelo, seems to have exhibited the great canons of art; one which has regulated all the modern cathedrals of Europe, for they are, in fact, but repetitions of it; and one, therefore, which requires a lengthened notice in this place, as intimately connected with the rapid progress of the Roman school. The ancient Basilica of St. Peter had become so ruinous that Pope Nicholas V., a man who delighted in magnificent undertakings, a lover of architecture, and of more than ordinary genius, had conceived the project of rebuilding it, and under the designs of Bernardo Rosellini had actually seen a portion of the design rise from the ground before his death. The project seemed then to be forgotten and abandoned, until Michael Angelo Buonarroti, seeking a place for the erection of the mausoleum of Julius II., upon which he was engaged, thought that the tribune of Rosellini's projected new basilica would be well suited for its reception, and accordingly proposed it to the pontiff. Julius, pleased with the suggestion, immediately sent for San Gallo and Bramante to examine into it. In these cases, one project generally suggests another, and the rearing a new St. Peter's became a fixed object in the mind of Julius II. The tribune of Nicholas V. was no longer thought of, except as a space to be included within the new works. He consulted several architects upon the subject; but the fact is, that the only real competition lay between Giuliano di San Gallo and Bramante. The last was the successful artist; and from a great number of projects the pope at last chose that upon which St. Peter's was afterwards commenced. The real design of Bramante can scarcely be traced in the basilica of the Vatican as executed. The changes it was doomed to undergo before completion, more than perhaps any other building was ever subjected to, have been drawn into a history by the Jesuit Bonanni. When Bramante died, his designs, if indeed he made any, were dispersed; and for what we do know of them we are indebted to Raffaello, who took much pains in collecting the ideas of our architect, as they afterwards appeared in Serlio's Treatise on Architecture. The original plan of Bramante was simple, grand, and in its parts harmonious, and would doubtless have been effective, far beyond the edifice as executed. It has been well observed by Q. de Quincy, in his *Life of Bramante*, "*Le Saint Pierre d'aujourd'hui paraît moins grand qu'il ne l'est en effet. Le Saint Pierre de Bramante aurait certainement été plus grand encore en apparence qu'en réalité.*" There would moreover have been an accordance between the interior and exterior. The peristyle was to have three ranks of columns in depth, which would have necessarily had unequal intercolumniations. The cupola was rather that of the Pantheon, ornamented exteriorly with an order of columns. Bramante carried his imitation even to the steps round the springing of that monument. From the medals of the design struck about the period, it seems that the façade was to have been decorated at its extremities with two campanili; but the authority of a medal may be doubtful. The idea, therefore, which is said to have originated with Michael Angelo, of placing the dome of the Pantheon upon the vaulting of the Temple of Peace emanated from Bramante, though the honour of actually carrying such a project into execution belongs to Michael Angelo da Buonarroti. It is not, however, probable that if Bramante had lived he could have strictly executed the design he produced; for it has been well proved that the piers which carry the dome would not have been sufficiently substantial for the weight to be placed upon them, inasmuch as Bramante's cupola would have been much heavier than that executed by Michael Angelo, and that architect considered it necessary to make his piers three times as thick as the former had proposed for his cupola. Bramante's general design having been adopted by Julius II., was immediately commenced with a boldness and promptitude of which few but such men as Julius and Bramante were capable. One half of the ancient basilica was taken down; and on the 18th of April, 1506, the first stone of the new fabric was laid by the pope in the pier of the dome, commonly called that of Sta. Veronica. The four piers soon rose; the centres were prepared for connecting them by vaults, which were actually turned. The weight and thrust of the vaults, however, bent the piers, and cracks and fissures made their appearance in every direction. Thus, without more than their own weight, much less that of the cupola, the works threatened ruin. The great haste used in carrying on the

works had doubtless much contributed to this catastrophe. Bramante in the meantime dying, Raffaele, Giocondo, and Giuliano di San Gallo, and afterwards Baldazzare Peruzzi and Antonio San Gallo, were engaged on the edifice, and severally used the proper means for remedying the defects that had arisen, and for fortifying the great piers of the dome. To do this, as well as to push forward its completion, Michael Angelo was employed; and the rest of that great man's life was chiefly devoted to carrying on, under his own designs, the works of the fabric. From the death of Bramante in 1513 to 1546, when Antonio San Gallo died, the architects above named, all of whose names are almost sacred, had been more or less employed upon it. It was during this period that Bramante's original plan of a Latin was changed into a Greek cross by Peruzzi. The works had at this time become the source of much jobbing; every body that had any employment on them seemed bent on providing for himself, when Michael Angelo consented, for he was far from desirous of being employed, to superintend the future progress of the fabric. The first use made of his authority by Michael Angelo was that of discharging all the agents and *employés* of the place; he may be said to have again driven the money-lenders out of the temple. That he might have more moral power over this worthless race, he set the example of declining to receive the salary of 600 crowns attached to his appointment as architect, and gratuitously superintended the works during the period of seventeen years,—a disinterestedness that afterwards found a parallel in one of the greatest architects that this or any other country ever saw: we needly scarcely mention the name of Inigo Jones. Michael Angelo began by undoing what his predecessor San Gallo had executed; and after having accomplished that, his whole powers were directed towards carrying on the structure to such a point that no change could possibly be made in his plans; so that after having strengthened the great piers, vaulted the naves, and carried up the exterior pedestal of the cupola, at the death of Paul III. in 1549 the form of these parts of the basilica was unchangeably fixed. Under Julius III., the successor of Paul, the intrigues which had always been carried on against Michael Angelo were renewed. He was accused of having contrived the arrangement without sufficient light, and of having changed every thing his predecessors had done. Thus proceeded this great work; but notwithstanding the severe trials he had to undergo from the envy of his contemporaries,—rivals he could not encounter,—Buonarroti steadily pursued his course. He felt that his own destiny and that of the fabric were identical; and, notwithstanding all the disgusting treatment to which he was exposed, determined to stand to his post while life remained. Writing to Vasari, he says, "For me to leave this place would be the cause of ruin to the church of St. Peter, which would be a lamentable occurrence, and a greater sin. As I hope to establish it beyond the possibility of changing the design, I could first wish to accomplish that end; if I do not already commit a crime, by disappointing the many cormorants who are in daily expectation of getting rid of me." And in another letter to Messer Lionardo Buonarroti, in reply to the pressing instance of the grand duke to have him at Florence, he says, "I would prefer death to being in disgrace with the duke. In all my affairs I have endeavoured to adhere to the truth; and if I have delayed coming to Florence as I promised, the promise should have been construed with this condition, that I would not depart hence until the fabric of St. Peter's was so far advanced as to prevent its being spoiled by others, and my design altered; nor to leave opportunity for those thieves to return and plunder, as has been their custom, and as is still their hope. Thus placed by Divine Providence, I have exerted myself to prevent those evils. As yet, however, I have not been able to succeed in advancing the building to that point which I desire, from want of money and men; and being old, without any one about me to whose care I could leave the work, as I serve for the love of God, in whom is all my hope, I cannot abandon it." At this period, with the letter, to which we have not done sufficient justice in the translation, it is impossible not to sympathise, nor to be unaffected by the simple and unbending honesty of this honour to the race of man, independent of all our admiration of his stupendous power as an artist. At the age of eighty-seven, the pedestal being then ready for the reception of the cupola, he made a small model in clay for that important feature of his work, which was afterwards, to a scale, accurately under his direction, executed in wood; but deficiency in the funds prevented the progress of the building. To the height of upwards of 28 ft. above the exterior attic the cupola is in one solid vault, whose diameter is near 139 ft. at its springing, at which place its thickness is near 10 ft. exclusive of the ribs. As the inner and outer vaults are not concentric, the interval between them increases as they rise. Where they receive the lantern they are 10 ft. 7 in. apart. The construction of this dome proves the profundity of the architect's knowledge as a scientific builder to have equalled his superiority as an architect.

336. After the death of Michael Angelo, this cupola with its lantern was rigorously executed, upon the model he had left, by Jacopo della Porta and Domenico Fontana. His intentions were religiously respected, in the completion of the fabric, until the time of Pirro Ligorio, whom Pius IV. deprived of his situation for attempting to swerve from the model and substitute his own work.

337. Between the foundation of the church by Bramante, and its entire completion by

Carlo Maderno, as seen in *figs. 167. and 168.*, a century had elapsed, but during that century

Fig. 167.

PLAN OF ST. PETER'S.

Fig. 168.

HALF ELEVATION AND HALF SECTION OF ST. PETER'S.

architectural as well as graphical and plastic taste had undergone great changes; and though the first was still far from the vicious point to which Borromini carried it, the great principles of order and authority, as founded on the models of antiquity, were passed away, and no longer occupied the attention of the architect. The spirit of innovation, too often mistaken for genius, had made such inroads, that regularity of plan, simplicity of form,

and the happy union of taste with common sense had altogether disappeared. The part added to the edifice by Maderno appears in the plan with darker lines, by which it is seen that he added three arcades to the nave, in which the same ordonnance is continued.

338. Respecting the alteration in, or rather addition to the plan, it is, and is likely to continue, a moot point, whether this change by Maderno has injured the effect of the church. "There are," says De Quincy, "in the method of judging of works of architecture, so many different points of view from which they may be judged, that it is quite possible to approve of even contrary things." We are not ourselves disposed to censure the application of Maderno, though it cannot be denied that the symmetry of the fabric was in some measure destroyed by it. It is possible that the constant habit of seeing cathedrals with a prolonged nave, before we first saw St. Peter's, may have disposed us to look leniently at a point which so many better judges than ourselves have condemned. Michael Angelo's plan was, doubtless, one of great simplicity and unity. According to his intention, the cupola was the principal feature, the four arms of its cross being accessories which would not interfere with or lessen the effect of its grandeur, whose points of view could not be much varied. On the other hand, the edifice, enlarged according to the first project of Bramante, has acquired an immensity of volume, which, observes the author before quoted, one would be now sorry to see it deprived of. "*Ce sont deux grandeurs voisines sans être rivales.*" In its exterior, however, it must be admitted that the prolongation of the nave has not improved the effect; and that arose from the necessity of strictly conforming to the forms that existed. It is manifest that the number of divisions which resulted from the mixtilinear plan of Michael Angelo would not well sort with the extended mass which the nave created. It was absolutely necessary that it should be conformable with what had been completed; and the effect of this was lessening the elevation of the cupola in an almost fatal manner. The façade of entrance cannot in any way be defended; and it is much to be regretted that the fine entrance designed by the great master was lost to the world.

339. St. Paul's is, perhaps, the only great instance in Europe wherein the design was made and wholly carried into execution by the same architect. Works of this nature usually exceed the space of man's life. St. Peter's was altogether a century and a half in building. The change of architects is not the least inconvenience of such a state of things; for during so long a period such a change of taste arises that the fashion and style of an art are from accident scarcely the same at its commencement and end. Thus the church of the Vatican, which was begun by Bramante in a comparatively pure style, was, in the end, defaced by the vicious bizzarries of Borromini. It was fortunate Michael Angelo, so far foreseeing accidents of this nature, had fixed unchangeably the main features of his composition.

340. That the first idea of this stupendous fabric owes its origin to Bramante cannot be disputed; but its greatness, as conceived by him, is confined to the boast of placing the cupola of the Pantheon upon the vaulting of the Temple of Peace. The sketch of it given by Serlio is nothing like the cupola which was executed. On the other hand, what was executed by Michael Angelo was scarcely new after what Brunelleschi had accomplished at Sta. Maria del Fiore. This, however, was a chef d'œuvre of construction; that of St. Peter's was a chef d'œuvre of construction and architecture combined. What was new in it was, that it was the loftiest and largest of all works, ancient or modern, uniting in its vast volume the greatest beauties of proportion to simplicity and unity of form; to magnificence and richness of decoration a symmetry which gives harmony to the whole, considered by itself, and not less so when considered in relation to the mass of which it is the crown. The great superiority of this cupola over all others is visible in another point of view, which we shall more particularly notice in the account of St. Paul's in a subsequent page: it is, that the same masonry serves for the exterior as well as the interior, whereby an immense additional effect is gained in surveying it from the inside. All is fair; there is no masking, as in other cupolas that followed it.

341. Whatever opinions may be formed on the other works of Michael Angelo, no difference can exist respecting the cupola of St. Peter's. "Si tout," observes De Quincy, "ce qui avait été fait et pensé, ou projeté avant lui, en ce genre, ne peut lui disputer le prix de l'invention et de l'originalité, et ne peut servir qu'à marquer la hauteur de son génie, il nous semble que les nombreuses coupes élevées dans toute l'Europe depuis lui et d'après lui, ne doivent se considérer encore que comme autant d'échelons, propres à faire mieux sentir et mesurer sa supériorité." The bungling of Carlo Maderno at St. Peter's is much to be regretted. The arches he added to the nave are smaller in dimensions than those which had been brought up immediately adjoining the piers of the cupola; and, what is still more unpardonable, the part which he added to the nave is not in a continued line with the other work, but inclines considerably to the south: in other words, the church is not straight, and that to such an extent as to strike every educated eye. His taste, moreover, was exceedingly bad.

342. In the principal churches of Rome there is great similarity of plan ; they usually consist of a nave and side aisles, in which latter, chapels are ranged along the sides. The separation of the nave and aisles is effected by arcades. The transepts are not much extended, and over the intersection of them with the nave and choir a cupola generally rises. The chapels of the Virgin and Holy Sacrament are commonly in the transepts ; and the great altar is at the end of the choir, which usually terminates semicircularly on the plan. Unlike those of the Florentine school, the interiors of the Roman churches are decorated to excess. Pictures, mosaics, and marbles of every variety line the walls. A profusion of gilding imparts to them a richness of tone, and the architectural details are often in the highest state of enrichment. They are, indeed, temples worthy of the worship of the Deity. Yet, with all this magnificence, the façades are often mean ; and when a display of architecture is exhibited in them, it is produced by abuses of the worst class. They are generally mere masks ; for between the architecture of these false fronts and that of the interior there is no architectural connection. In very many instances the sides of the churches are actually hidden by adjacent buildings, so that they are altogether unseen ; a circumstance which may have conduced to the repetition of the abuse. Faulty, however, as these edifices are, to them is Europe indebted as models, which have in modern times been more purified. We have not space to enumerate or criticise the churches with which Rome abounds. St. Carlo on the Corso, by Onorio Longhi, is a fine example of them, and gives a fair notion of the general distribution we have described. Those of a later date, especially those by Borromini, may be considered as *indices rerum vitandarum* in architecture ; and though we are, perhaps, from the cupidity of upholsterers and house decorators, likely to be doomed to sit in rooms stuffed with the absurdities of the taste prevalent in the time of Louis XV., we can hardly conceive it necessary in these days to recommend the student's abhorrence of such freaks of plan and elevation as are to be found in the church of St. Carlo alle quattro Fontane, by that architect.

343. The palaces of Rome are among the finest architectural works in Europe ; and of those in Rome, as we have before observed, none equals the Farnese, whose façade is given in *fig. 169*. "Ce vaste palais Farnese, qui à tout prendre, pour la grandeur

Fig. 169.

FARNES PALACE.

de la masse, la régularité de son ensemble, et l'excellence de son architecture, a tenu jusqu'ici, dans l'opinion des artistes, le premier rang entre tous les palais qu'on renomme," is the general description of it by De Quincy, upon whom we have drawn largely, and must continue to do so. This edifice, by San Gallo, forms a quadrangle of 256 ft. by 185 ft. It is constructed of brick, with the exception of the dressings of the doors and windows, the quoins of the fronts, and the entablature and loggia in the Strada Giulia, which are of travertine stone. Of the same stone, beautifully wrought, is the interior of the court. The building consists of three stories, including that on the ground, which, in the elevations or façades, are separated by impost cornices. The only break in its symmetry and simplicity occurs in the loggia, placed in the centre of the first story, which connects the windows on each side of it by four columns. On the ground story the windows are decorated with square-headed dressings of extremely simple design ; in the next story they are flanked by columns, whose entablatures are crowned alternately with triangular and circular pediments ; and in the third story are circular-headed windows, crowned throughout with triangular pediments. The taste in which these last is composed is not so good as the rest, though they were probably the work of Michael Angelo, of whose cornice to the edifice Vasari observes, "È stupendissimo il cornicione maggiore del medesimo palazzo nella

facciata dinanzi, non si potendo alcuna cosa ne più bella ne più magnifica desiderare." The façade towards the Strada Giulia is different from the other fronts in the centre only, wherein there are three stories of arcades to the loggia, each of whose piers are decorated with columns of the Doric, Ionic, and Corinthian orders in the respective stories as they rise, and these in form and dimensions correspond with the three ranks of arcades towards the court. It appears probable that this central arrangement was not in the original design of San Gallo, but introduced when the third story was completed. Magnificent as from its simplicity and symmetry is the exterior of this palace, which, as De Quincy observes, "est un édifice toujours digne d'être le séjour d'un prince," yet does it not exceed the beauty of the interior. The quadrangle of the court is 88 ft. square between the columns of the arcades, and is composed with three stories, in which the central arrangement above mentioned towards the Strada Giulia is repeated on the two lower stories, over the upper whereof is a solid wall pierced in the windows. The piers of the lower arcade are ornamented with Doric columns, whose entablature is charged with triglyphs in its frieze, and its metopæ are sculptured with various symbols. The imposts of the piers are very finely profiled, so as to form the entablatures when continued over the columns of the entrance vestibule. In the Ionic arcade, over this, the frieze of the order is decorated with a series of festoons. The distribution of the different apartments and passage is well contrived. All about the building is on a scale of great grandeur. Though long unoccupied, and a large portion of its internal ornaments has disappeared, it still commands our admiration in the Carracci Gallery, which has continued to serve as a model for all subsequent works of the kind. The architecture of the Farnese palace, more especially as respects the arcades of its court, is the most perfect adaptation of ancient arrangement to more modern habits that has ever been designed. We here allude more particularly to the arcades, upon whose piers orders of columns are introduced. This species of composition, heavier, doubtless, less elegant, yet more solid than simple colonnades, is, on the last account, preferable to them, where several stories rise above one another. The idea was, certainly, conceived from the practice in the ancient theatres and amphitheatres; and in its application at the Farnese palace rivals in beauty all that antiquity makes us in its remains acquainted with. San Gallo, its architect, died in 1546.

344. It would be impossible here to enumerate the palaces with which Rome abounds; but we must mention another, that of St. Giovanni Laterano, by Domenico Fontana, as a very beautiful specimen of the palatial style. Milizia censures the detail of this edifice, and there is some truth in his observations in that respect; but the composition is so simple and grand, and the cornice crowns it with so much majesty, that the detail is forgotten in the general effect, and its architect well deserves the rank of a great artist.

345. The villas, *Ocelli d'Italia*, as they have been called, round the suburbs of Rome, are in a style far lighter than the palaces whereof we have just been speaking. They are the original models of the modern country houses of this island, and exhibit great skill in their plans and elegance in their façades. Generally they rose from the riches and taste of a few cardinals, who studded the environs of the Eternal City with some of the fairest gems of the art. MM. Percier and Fontaine published a collection of them at Paris, from which we extract the Villa Pia (fig. 170.). It was designed by Pirro Ligorio, a Neapolitan

Fig. 170.

VILLA PIA.

architect, who died in 1580, and is thus described by the authors whose view of it we have borrowed. "It was built," say they, "in imitation of the houses of the ancients, which Ligorio had particularly studied. This clever artist, who to his talent as an architect joined the information of a learned antiquary, here threw into a small space every thing that could contribute to render it a delightful dwelling. In the midst of verdant thickets, and in the centre of an amphitheatre of flowers, he constructed an open lodge, decorated with stuccoes and agreeable pictures. The lodge is raised upon a base, bathed by the water of a basin, enclosed with marbles, fountains, statues, and vases. Two flights of steps, which lead to landings sheltered by walls ornamented with niches and seats of marble, offer protection from the sun's rays by the trees that rise above them. Two porticoes, whose interior walls are covered with stuccoes, lead on each side to a court paved in mosaic work. This is enclosed by a wall, round which seats are disposed. Here is a fountain spouting up from the centre of a vase of precious marble. At the end of the court facing the lodge an open vestibule, supported by columns, fronts the ground floor of the principal pavilion; and is decorated with mosaics, stuccoes, and bassi-relievi of beautiful design. The apartments on the first floor are ornamented with fine pictures. Finally, from the summit of a small tower, which rises above the building, the view extends over the gardens of the Vatican, and the plains through which the Tiber takes its course, and the splendid edifices of Rome." For further information on the Roman villas, we refer the reader to the work we have quoted.

346. The Roman school of architecture, founded by Bramante, includes San Gallo, Buonarroti, Sansovino, Peruzzi, Vignola (whose extraordinary palace at Caprarola deserves the study of every architect), and many others. It ends with Domenico Fontana, the period of its duration being from 1470 to 1607, or little more than 130 years.

347. Before we proceed to the Venetian school, it will, however, be proper to notice two architects, whose works tended to change much for the worse the architecture of their time; we mean Borromini and Bernini, though the latter was certainly purer in his taste than the former. Borromini, whose example in his art was followed throughout Europe, and who, even in the present day, has his returning admirers, was the father of all modern abuses in architecture; and the reader must on no account confound his works with those of the Roman school, which had ceased nearly half a century before the native of Bissona had begun to practise. He inverted the whole system of Greek and Roman architecture, without replacing it by a substitute. He saw that its leading forms, sprung from a primitive type, were, by an imitation more or less rigorous, subjected to the principles of the model from which its order and arrangement emanated. He formed the project of annihilating all idea of a model, all principles of imitation, all plea for order and proportion. For the restriction in the art resultant from the happy fiction, or perhaps reality of a type, one whose tendency was to restrain it within the bounds of reason, he substituted the anarchy of imagination and fancy, and an unlimited flight into all species of caprice. Undulating flexibility supplanted all regularity of form; contours of the most grotesque description succeeded to right lines; the severe architrave and entablature were bent to keep up the strange delusion; all species of curves were adopted in his operations, and the angles of his buildings were perplexed with an infinite number of breaks. What makes this pretended system of novelty more absurd is (and we are glad to have the opportunity here of observing that the remarks we are making are applicable to the present fashionable folly of decorating rooms *à la Louis XIV. and XV.*), that its only novelty was the disorder it introduced, for Borromini did not invent a single form. He was not scrupulous in retaining all the parts which were indicated by imitating the type; he decomposed some, transposed others, and usually employed each member in a situation directly the reverse of its proper place, and, indeed, just where it never would be naturally placed. Thus, for example, to a part or ornament naturally weak, he would assign the office of supporting some great weight; whilst to one actually capable of receiving a great load, he would assign no office whatever. With him every thing seems to have gone by contraries; and to give truth the appearance of fiction, and the converse, seems to have been his greatest delight. Out of all this arose a constant necessity for contrivance, which marked Borromini as a skilful constructor, in which respect he attained to an extraordinary degree of intelligence. It seems, however, not improbable that one of his great objects in studying construction was, that he might have greater facility in carrying his curious conceits into execution; for it may be taken almost as an axiom in architecture, so great is the relation between them, that simple forms and solid construction are almost inseparable; and it is only necessary to have recourse to extraordinary expedients in construction when our productions result from an unrestrained imagination. Further notice of this architect is not necessary; one of his most celebrated works is the restoration of the church of St. Giovanni Laterano, — after St. Peter's, the greatest in Rome. His purest work is the church of St. Agnese; whilst that of St. Carlo alle quattro fontane, which we have heretofore noticed, is the most *bizarre*. Borromini died in 1667.

348. Bernini, the other artist whom we have mentioned, was equally painter, sculptor,

and architect; his principal work is the colonnade in front of St. Peter's. He was, notwithstanding the abuses to be found in his works, a man of great talent. In their general arrangement his buildings are good and harmonious; his profiles are graceful; his ornaments, though sometimes profuse, are usually elegant. Bernini, however, was no check upon the pernicious character of his cotemporary Borromini; instead, indeed, of relieving architecture of some of her abuses, he encumbered her with fresh ones. He was also fond of broken pediments, and of placing them in improper situations. He employed undulations, projections innumerable, and intermixtures of right lines with curves; for beautiful simplicity he substituted elegant fancy; and is to be imitated or admired by the student no farther than he followed nature and reason. He made some designs for the Louvre at Paris, which are exceedingly good. His death occurred in 1680.

349. 3. *The Venetian School* is characterised by its lightness and elegance; by the convenient distribution it displays; and by the abundant, perhaps exuberant, use of columns, pilasters, and arcades, which enter into its composition. Like its sister school of painting, its address is more to the senses than is the case with those we have just quitted. We have already given an account of the church of St. Mark, in the 12th century; from which period, as the republic rose into importance by its arms and commerce, its arts were destined to an equally brilliant career. The possession in its provinces of some fine monuments of antiquity, as well as its early acquaintance with Greece, would, of course, work beneficially for the advancement of its architecture. That species of luxury, the natural result of a desire on the part of individuals to perpetuate their names through the medium of their habitations, though not productive of works on a grand or monumental scale, leads, in a democracy (as were the states of Venice), to a very general display of moderately splendid and elegant palaces. Hence the extraordinary number of specimens of the building art supplied by the Venetian school.

350. San Micheli, who was born in 1484, may, with propriety, be called its founder. Having visited Rome at the early age of sixteen for the purpose of studying its ancient monuments of art, and having in that city found much employment, he, after many years of absence, returned to his native country. The mode in which he combined pure and beautiful architecture with the requisites called for in fortifications may be seen displayed to great advantage at Verona, in which city the *Porta dell Pallio* is an instance of his wonderful ingenuity and taste. But his most admired works are his palaces at Verona; though, perhaps, that of the Grimani family at Venice is his most magnificent production. The general style of composition, very different from that of the palaces of Florence and Rome, is marked by the use of a basement of rustic work, wherefrom an order rises, often with arched windows, in which he greatly delighted, and these were connected with the order after the manner of an arcade, the whole being crowned with the proper entablature. As an example, we give, in *fig. 171.*, the façade of the Pompei palace at Verona. The genius of

FIG. 171.

POMPEI PALACE, VERONA.

San Micheli was of the very highest order; his works are as conspicuous for excellent construction as they are for convenience, unity, harmony, and simplicity, which threw into shade the minor abuses occasionally found in them. If he had no other testimony, it would be sufficient to say, that for his talents he was held in great esteem by Michael Angelo; and our advice to the student would be to study his works with diligence. San Micheli devoted himself with great ardour to the practice of military architecture; and though the invention was not for a long time afterwards assigned to him, he was the author of the

system used by Vauban and his school, who, for a long period, deprived him of the credit of it. Before him all the ramparts of a fortification were round or square. He introduced a new method, inventing the triangular and pentangular bastion, with plain fossés, flanks, and square bases, which doubled the support; he moreover not only flanked the curtain, but all the fossé to the next bastion, the covered way, and glacis. The mystery of this art consisted in defending every part of the inclosure by the flank of a bastion; hence, making it round or square, the front of it, that is, the space which remains in the triangle, which was before undefended, was by San Micheli provided against. We cannot, however, further proceed on this subject, which belongs to military, which at that period was intimately connected with civil architecture. The *Porta del Pallio* at Verona has been mentioned; that city, however, contains another gate of great architectural merit by this master, the *Porta Nuova*, a square edifice, supported within by a number of piers of stone, with enclosures or apartments for the guards, artillery, &c. The proportions, as a whole, are pleasing; it is of the Doric order, devoid of all extraneous ornament, solid, strong, and suitable to the purposes of the building. Except in the middle gate and the architectural parts, the work is rusticated. The exterior façade stands on a wall, with two large pyramidal pilasters of marble rising from the bottom of the fosse; at the top are two round enclosures approaching almost to towers. In the interior, to the two gates near the angles are two corresponding long passages, vaulted, leading to a number of subterraneous galleries and rooms. For beauty, however, we do not think this gate so beautiful as that of del Pallio, which we here give (*fig. 172.*). But the gem of this great master is the little circular

Fig. 172.

PORTA DEL PALLIO, VERONA.

chapel at San Bernardino, whose beauty, we think, has scarcely ever been surpassed, and which exhibits, in a striking degree, the early perfection of the Venetian school. It was not finished under San Micheli, and blemishes are to be found in it; it is nevertheless an exquisite production, and, in a surprisingly small space, exhibits a refinement which elsewhere we scarcely know equalled. The works which he designed surpass, we believe, in number those of all the masters of Italy, Palladio, perhaps, excepted. He gave a tone to his art in the Venetian states, which endured for a considerable period. His death occurred in 1549.

351. Contemporary with San Micheli, was another extraordinary genius of this school, born at Florence,—Jacopo Tatti by name, but more usually called Sansovino, from the country of his master, Andrea Contucci di Monte Sansovino. Such was the respect for this artist in Venice, his adopted city, that at a moment when it became necessary to raise by means of taxation a large sum on the citizens, the senate made a special exemption in favour of him and Titian. The Roman school might lay claim to him, if the works he executed at Rome, and not his style, would justify it; but that is so marked, so tinged with the system of arcades with orders, its distinguishing feature, that an inspection of his works will immediately satisfy even a superficial observer. He was a great master of his art; and though he does not in so great a degree appear to have profited by the examples of antiquity as the architect last named, he has left behind buildings, which, for picturesque effect, leave him little inferior in our rating. He was the architect of the library of St. Mark at Venice, a portion whereof is given in *fig. 173.*; a building of noble design, notwithstanding the improprieties with which it is replete. It consists of two orders; the lower one of highly ornamented Doric, and the upper one Ionic and very graceful in effect. Of both these orders, as will be seen in the figure, the entablatures are of inordinate comparative height. The upper one was expressly so set out for the purpose of exhibiting the beautiful sculptures with which it is decorated. The cornice is crowned with a balustrade, on whose piers statues were placed by the ablest scholars of Sansovino. A portico occupies the ground floor, which is raised three steps from the level of the piazza. This portico consists of twenty-one arcades, whose piers are decorated with columns. In the interior are arches corresponding to the external ones, sixteen whereof, with their internal apartments, are appropriated for shops. Opposite the centre arch is a magnificent staircase leading to the hall, beyond which is the library of St. Mark. The

FIG. 175.

LIBRARY OF ST. MARK.

among the finest of Venice, is also by him; as is that of San Martino and many others. Jacopo was fertile in invention: his architecture was full of grace and elegance; but he was deficient in a thorough knowledge of construction, which, in the library of St. Mark, brought him into disgrace, of which, from all accounts, the builders ought to have suffered the principal share. He continually introduced the orders, and especially the Doric and Composite. The members of his entablatures were much sculptured; but his ornaments were extremely suitable and correct. In statues and bassi relievi he greatly indulged, thereby adding considerably to the effect and majesty of his buildings. Scamozzi mentions a work by him on the construction of floors, and particularly describes a method adopted by him for preventing dust falling through the joints of the boards. The work has been lost. Sansovino died in 1570.

352. After such artists as San Micheli and Sansovino, it would have seemed to an ordinary mind difficult to have invented new forms, or rather so to have modified the old ones as to be original. Andrea Palladio, however, not only knew how to be original, but to leave his works as models for the countries of Europe, in which the style which bears his name has had no rival; so true is it, in all the arts, that there is always room to be found for a man on whom nature has bestowed the faculty of seeing, feeling, and thinking for himself. In the case of the architect something more than genius is necessary: it is requisite that circumstances should exist by which his art may be developed, or, in other words, that what he is capable of producing may at the time be suitable to the wants of society. Such circumstances existed for a long period in Italy, where, up to the time at which we are arrived, the rich and great had been contending with the governments which should be the greatest patrons of the art. Hence sprung the multitude of extraordinary works in the country named, which still point out the greatness in art at which it had arrived, when it was one of the really necessary arts. Neither in the Venetian states, nor at the time when he rose into reputation, which was about the middle of the sixteenth century, had Palladio that opportunity of signalising himself which had occurred to many former masters. Venice had risen into power and wealth by its arms and commerce; was the natural protectrix of the art; and although the works she required were not on scales of the grandest dimensions, yet those which her citizens required kept pace in luxury with the increasing wealth of the families by whom they were required. This was the career open to the genius of Palladio. Architecture in these states was not called upon to furnish churches of colossal dimensions, nor palaces for sovereigns, nor immense public monuments left for posterity to finish. The political state of the country, very luckily for his talents, furnished a numerous class of citizens who contended which should procure for himself the aid of this great man in rearing a villa or palace, and which might serve the

faults of this building, which are very many, are lost in its grace and elegance, and it is perhaps the chef d'œuvre of the master. Whilst Sansovino was engaged on it he propounded an architectural problem, which reminds us very much of the egg of Columbus: "How can the exact half of a metope be so contrived as to stand on the external angle of the Doric frieze?" The solution, clumsy as that of the navigator with his egg, practised in this building, is, however, a bungling absurdity; namely, that of lengthening the frieze just so much as is necessary to make out the deficiency. Sansovino was invited to pass into France, where he gave some designs, which tended to the advancement of the art in that country. On his return he built the Zecca, or mint, one of his finest works. Another of his extraordinary productions is the palace of the Comari, on the Grand Canal at San Maurizio. The church of San Fantino,

double purpose of a present dwelling for, and a future memorial of, his family,—a passion that covered the banks of the Brenta with edifices which, of their class, form a complete school of civil architecture.

353. The taste of Palladio was tempered by the care he bestowed on accommodating exterior beauty to interior convenience, and by suiting the art to the wants of persons with moderate means, through the medium of greatness without great dimensions, and richness of effect without great outlay. In the imitation, or rather appropriation, of the architecture of the ancients, none of his predecessors of any of the schools had so luckily hit on that just medium of exactness without pedantry, of severity without harshness, of liberty without licentiousness, which have since made the architecture of ancient Greece popular, and so modified it as to be practicable and convenient in all countries. We here speak, of course, of the elements, and not the combinations, of Greek art, and of it changed by a passage through an intermediate state during the existence of the Roman empire. No architect can consider himself thoroughly educated who has not studied the works of Palladio. “*De fait,*” says De Quincy, in his *Life of this architect*, “*il n’est point d’architecte qui, après avoir formé ou réformé son style sur les grands modèles de l’art des anciens, et des premiers maîtres de l’Italie moderne, ne se croie pas obligé d’aller encore étudier dans la patrie et les œuvres de Palladio, un genre d’applications plus usuelles, et plus en rapport avec l’état de nos mœurs ; c’est-à-dire, le secret d’accommoder tour-à-tour, et nos besoins aux plaisirs d’une belle architecture, et l’agrément de celle-ci aux sujétions que de nouveaux besoins lui imposent.*” It was from the peculiar properties of Palladio’s taste and style, suited as they are to more moderate fortunes, that they found in England a second native country (if such an expression may be allowed), where Inigo Jones, Wren, Gibbs, Taylor, Chambers, and many others, have naturalised the plans, façades, distribution, and details which were originally planted in the provinces of the Venetian republic. Indeed, the style of Palladio could not be prevented from spreading through Europe, as a mean between the severe use of ancient forms and the licentious style of those who reject all rules whatever. The buildings by him exhibit great good sense, simple means of accomplishing the end, a satisfactory agreement between the demands of necessity and pleasure, and such an harmony between them that it is hard to determine which has submitted to the other. The interior distribution of his palaces and villas in respect of plan would, without considerable modification, be but ill suited to modern habits. We give, in *fig. 174. (see next page)*, a plan and elevation of the Villa Capra, one of his most celebrated works of that class. Convenience changes as the mode of life varies; indeed, except in a private building of large extent, the large quadrangular court of the houses of Italy is here unknown. Palladio’s plans, however, were convenient to those for whom they were executed; and in that way they must be judged. With his eyes constantly turned to the practice and detail of the ancients, he acquired a bold, simple, and agreeable style; and, his churches excepted, the beauties of the master are to be sought in his façades, and the quadrangles of his palaces. Pedestals, either with panels or raisings, were always avoided by him; his architraves were rarely sculptured; and the upper ornaments of his entablatures were always carefully centred above each other. His doors, windows, and niches are composed with great simplicity; and pediments, when used, are unbroken. In the members of his cornices he never lost sight of the character of the order employed, and was extremely particular in duly adjusting its profiles. He, however, did not scruple to vary the proportions of an order according to the nature of the building to which it was applied; and in the proportions of his churches and apartments he seems to have delighted, as afterwards did Sir Christopher Wren, in arithmetical, geometrical, and harmonic proportions. Though extremely partial to the use of the Ionic order, yet the others were not unfrequently used by him. His Corinthian capital is not to be praised; it is profled very clumsily, and ought not to be followed. The domes which he erected are almost invariably hemispherical. It is not to be supposed that his buildings are perfect, though they approach perfection; but it is more than probable that many of the abuses we see in them arose either from want of sufficient superintendence, the number he designed being very great, or that they were introduced after his death. This, we think, may be safely assumed, because the instructions in his work on architecture are very peremptory on the subject of abuses. So well based upon the practice of the ancients does the style of our master appear to be, that it is, with but few modifications, suited to all nations, and just such as the ancients themselves would have adopted. “*Les fermes,*” observes Le Grand in his *parallèle*, “*que dirigeait Palladio et qu’il couvrait de tuiles on d’un chaume rustique, l’emportent de beaucoup sur les palais somptueux de Borromini, ou sur les riches et bizarres productions de Guarino Guarini.*” Certain, indeed, it is that simplicity, unity, and style are more powerful means of producing grandeur, than great volume or large masses unskilfully handled. A fine instance of this is seen in the façade of the Thiene palace at Vicenza, *fig. 175. (See next page.)*

354. The number of palaces and villas with which Palladio enriched the Venetian and Vicentine territories is almost incredible: the variety of plan and elevation in them seems as inexhaustible as their number. To the buildings above referred to may be added the

Fig. 174.

PLAN, ELEVATION, AND SECTION OF VILLA CAPRA.

Fig. 175.

ELEVATION AND SECTION OF PALAZZO THIENE.

Carità at Venice, which is a lovely specimen of his style. His grandest church is that Del Redentore at Venice. Generally in the façades of his churches there are abuses, whereof it is scarcely credible he would have been guilty; such are the two half pediments in the church we have just mentioned. The theatre built upon the ancient model for the Olympic Academy at Vicenza gained great reputation for him. Palladio died in 1580.

355. The last architect of the Venetian school who obtained celebrity was Vincenzo Scamozzi. The son of an architect, and born in a country which had become the nursery of the art, his powers were exhibited at an early age. Like Palladio and other great masters, he selected for his principal guides the antiquities of the Eternal City, and the precepts of Vitruvius, whose work at that period was considered of high importance, as in truth it really was. There is no doubt that Scamozzi was much indebted to the works of Palladio, although he affected occasionally to decry them; but, in opposition to De Quincy, we think that his style is more founded on that of San Micheli or Sansovino. This is, however, of little importance; for his natural talents were of a very high order. At a very early period of his career, so great was his reputation that he was employed by the canons of San Salvatore in opening the lantern to the cupola of their church; a task in which it appears that he acquitted himself with great ability. For the upper order of the Procurazie Nuove at Venice he has often been unjustly reproached, because he did not confine himself to two stories, so as to complete the design of Sansovino. The design of Scamozzi, had it been continued in the Piazza San Marco, would have placed in the back ground every other piazza in Europe. The two lower stories of the Procurazie Nuove are similar in design to the Library of S. Marco; and it is greatly to be regretted that Scamozzi was so much otherwise occupied that he had not the opportunity of watching the whole of its execution, which would have extended to thirty arcades, whose whole length would have been 426 feet. Scamozzi only superintended the first thirteen; the three built by Sansovino excepted, the rest were trusted to the care of builders rather than artists, and, from the little attention bestowed upon preserving the profiles, exhibit a negligence which indicates a decline in the arts at Venice. Scamozzi is placed in the first rank as an architect by his design for the cathedral at Saltzburg, whither he was invited by the archbishop of the see. This church, which was not completed till after his death in 1616, is 454 ft. long, and 329 ft. wide, being in the form of a Latin cross on the plan, over whose centre a cupola rises. The distribution of the interior is with a nave and two side aisles; the former whereof is 64 ft. wide, and 107 ft. high. Scamozzi's employment was very extended, and his country has to lament it; for fewer commissions would have insured greater perfection in their execution, which, in those that exist, is often unworthy of the name of the master. Scamozzi published a work on the art, which will be found in our list of authors at the end of this work. He died in 1616.

356. Besides Giovanni da Ponte and Alessandro Vittoria, the Venetian school contains the names of few more than those we have named: they appear to have commanded the whole of the employ of the states and neighbourhood of Venice for a period of about 110 years, ending in 1616. When, however, it no longer continued to grow and flourish in its native soil, its scions, grafted throughout Europe, spreading their branches in every country, prospered wherever they appeared. On the former of the two architects just named, a few observations are necessary. He died in 1597, at the age of eighty-five years. Principally occupied in the reparation and re-establishment of the buildings of the city that had fallen into decay, he was nevertheless engaged on some considerable works; among which was the great hall of the arsenal at Venice, 986 feet long, and the more celebrated work of the Rialto Bridge, whence he obtained the sobriquet *Da Ponte*, and for the execution whereof he competed with Palladio and Scamozzi. The span of the single arch of which the work consists is about 72 ft., and the thickness of the arch stones about 4 ft. 4 in. It is segmental, and the height from the level of the water is about 22 ft. 9 in. The width of the bridge is equal to the span of the arch, and this width is divided longitudinally into five divisions, that is, into three streets or passages, and two rows of shops. The middle street or passage is 21 ft. 8 in. wide, and the two side ones near 11 ft. The number of shops on it is twenty-four. The last work of Da Ponte was the construction of the prisons away from the ducal palace. This edifice is a quadrilateral building, with a portico of seven arcades. A story rises out of it pierced by seven great windows decorated with pediments, and it is joined to the palace by the bridge so well known under the name of *Il Ponte dei Sospiri*. The work was not carried to completion during Giovanni's life, but was finished by his nephew Contino. In his church on the Grand Canal, constructed for the nuns of Santa Croce, there is little merit except that of solidity; indeed, he does not appear to have possessed much taste, as may be inferred from the two ranks of columns in the hall of the arsenal above mentioned, which cannot be said to belong to any of the species of columns usually employed. The solid character of the great prison is appropriate, and more in consonance with the rules of the art.

## SECT. XVII.

## FRENCH ARCHITECTURE.

357. The architecture of Europe from the middle of the sixteenth century was founded on that of Italy. Of its value, the French and the English seem to have a stronger perception than the rest of the nations. We shall therefore now consider the architecture of France: that of England from a much earlier date will be separately considered in the succeeding chapter. Philibert Delorme was among the first of the architects of France who promoted a taste for good architecture; and though in some respects he may have been surpassed by other artists of his time, in others, whether connected with theory or practice, he has left his rivals a great distance behind him. Although he might not have had the purity of detail of Jean Bullant, nor the richness of invention and execution of P. Lescot, he has acquired by his talent in construction a reputation which has survived his buildings. The Queen Catherine of Medicis having resolved upon the construction of a palace at Paris, which should far surpass all that had previously been done in France, resolved upon placing it on a spot then occupied by some tile kilns (Tuileries) in the faubourg St. Honoré, and committed the design and erection to Delorme. It is, however, contended by some that Jean Bullant was joined with him in the commission. If that was really the case, it is probable that the labours of the latter were confined to details of ornament and execution, rather than to the general design and disposition. What, if it was so, belonged to each is not now to be discovered; but the genius of Delorme has survived all the revolutions the celebrated building in question has undergone. Catherine seems not to have been satisfied with the works; for she appears to have begun another palace on the site of the Hotel Soissons, that of the present Halle au Bleds, and to have entrusted this to the care of Jean Bullant. That of the Tuileries was in the end continued by Henri IV.; enlarged by Louis XIII. on the same line, after the designs of Du Cerceau, with two main bodies and two composite pavilions; all which were in the time of Louis XIV. afterwards brought together by the designs of Leveau and Dorbay. In the centre pavilion all that now remains of Delorme's work is the lower order of Ionic columns. This morsel of Delorme exhibits a good Ionic profile in the order, and is one of his best works. Generally speaking, the profiles of this master, which Chambrai has admitted into his *Parallèle*, make one acknowledge the justice of that author's observation, that he had "un peu trop vu les plus belles choses de Rome, avec des yeux encore préoccupés du style Gothique. Le talent de cet architecte consistait principalement dans la conduite d'un bâtiment, et de vrai il était plus consommé en la connoissance et la coupe des pierres que dans la composition des ordres; aussi en a-t-il écrit plus utilement et bien plus au long." Delorme was the author of two works on architecture: one, *Un Traité complète de l'Art de Bâtir*, on architecture generally; the other, *Nouvelles Inventions pour bien bâtir et à petits frais*. The last relates more especially to a practice in carpentry, which, on the Continent, has been put into execution with great success, its principle being still constantly applied. The method of carpentry invented by Delorme, and which still goes in France by his name, consists in substituting for the ordinary system of framing and rafters curved ribs, in two thicknesses, of any sort of timber, three or four feet long, and one foot wide, of an inch in thickness, and which are connected in section and tie according to the form of the curve, whether pointed, semicircular, or segmental. These arches, in order to be strong and solid, should be fixed at their feet on plates of timber framed together, lying very level on the external walls; and the planks which are to form the principal curve are to be placed accurately upright on their ends, in which situation they may be kept by braces morticed into them at convenient distances, and retained in their places by wedges, for it is essential to the strength of this species of carpentry that it should be kept in a vertical position. In this country the species of carpentry just mentioned has never been practised to the extent it deserves. Delorme died in 1570. With him was cotemporary Jean Bullant, whose name has been just mentioned, and who, whilst San Gallo was occupied on the Palazzo Farnese, was raising the Château d'Ecouen, in which the prelude to good taste is manifest, and in whose details are exhibited the work of an architect very far advanced above his time, and capable of raising the art to a much higher pitch of excellence than it enjoyed, had not the habits of the nation restrained him in his useful course. A considerable portion of the façade of the Tuileries towards the Carousel is suspected to have been the work of Bullant; but the château of Ecouen, built, or rather begun, about 1540, for the constable Montmorency, was almost the first step to the establishment of pure architecture in France, and its architect may fairly be named the Inigo Jones of the French.

358. By the wars in Italy under Charles VIII., Louis XII., and Francis I., the French had become intimately acquainted with the architecture of Italy, and the taste of the monarch last named induced him to bring from that country some of their most celebrated artists; so that in France there was almost a colony of them. Among them, fortunately

for the quicker working of good taste, was the celebrated Vignola, who resided in France many years; a circumstance which may, with some probability, account for the high esteem in which that great master's profiles have always been held, and indeed in which they are still held there, though, generally speaking, the French have invariably been more attached in their practice to the Venetian than to the Roman school. Serlio, another Italian architect of note, was employed in the country by Francis, and actually died at Fontainebleau. At the period whereof we are now treating there appears to have been a number of able artists; for to Delorme and Bullant must be added Lescot, who, with Jean Gougeon as his sculptor, was many years employed upon the building usually called the *Vieux Louvre*, to distinguish it from the subsequent additions which have quadrupled the original project of Lescot. To judge of the works of the French architects of this period, a relative, and not an abstract view, must be taken of them; relative, we mean, to the general cultivation of the arts when any individual artist appears. In this respect Lescot's works at the Louvre are entitled to the greatest praise; and from the examples he as well as Bullant and Gougeon afforded, it might have been expected that pure architecture would have proceeded without check until it reached a point as high as that to which it had been carried in Italy. Such was not, however, to be the case. Mary de Medicis, during her regency, having determined on building the Luxembourg palace, was anxious to have it designed in the style of the palaces of Florence, her native city. Jacques de Brosse, her architect, was therefore compelled to adopt the character required: his prototype seems to have been the Pitti palace, and his version of it is a failure. The gigantic palaces of Florence well enough bear out against the rustic and embossed work employed upon them; but when their scale is reduced, the employment of massive parts requires great caution. The palace, however, of the Luxembourg became a model for the fashion of the day, and produced an intermediate style, which lasted many years in France, and arrested the arrival at perfection whereof the above work of Bullant and others had opened a fair prospect. De Brosse was an able artist, and his design for the façade of St. Gervais of three orders is, under the circumstances, entitled to our praise. This architect acquired much honour by the aqueduct of Arcueil, the completion whereof, in 1624, it is supposed he did not long survive.

359. Under Louis XIV. the art remained for the most part in the intermediate state just noticed; and yet that monarch and his minister Colbert lost no opportunity of embellishing the kingdom with its productions. He employed Bernini to make designs for the palace of the Louvre; and for that purpose induced the artist to visit France, where he was received with the highest respect. He left a design for a façade of the building in question, which, though in a corrupt style, exhibits nevertheless marks of grandeur and magnificence which would have been worthy of the monarch. Bernini, disgusted, as he alleged, with the workmen of Paris, departed from the country without leaving any example of his architectural powers. That he did so France has no reason to lament, since it gave Perrault the opportunity of ornamenting the capital with one of the most splendid monuments of the art which Europe can boast. To Perrault is the credit due of having given an impulse to French architecture it has never lost, and of having changed the heavy style of his time into the light and agreeable forms of the Venetian school. The beauties of the façade of the Louvre (*fig. 176.*) are so many and great that its defects are forgotten. The

Fig. 176.

HALF FAÇADE AND HALF PLAN OF LOUVRE.

proportions are so exquisite, that the eye cannot rest on the coupled columns and the arch of the principal gate rising into the story of the colonnade. The original profession of Perrault was that of medicine, which, however, he only exercised for the benefit of his friends and the poor; hence the design he made with others in competition for the above work having been successful, he was associated for its execution with Louis le Veau, the king's principal architect. From the variety of sciences in which Perrault excelled, it is not probable that the assistance of a practical architect was actually necessary; indeed the four volumes which he published under the title *Essais de Physique*, and the collection of machines for raising and removing great weights, which he also published, show that he was, without assistance, quite competent to the charge which was committed to him with others. He built the observatory at Paris, possessing an originality of character which Milizia says is very conformable to its purpose. But however suitable it may have been considered at the time of its erection, and it cannot be denied there is a fine masculine character about it, it is for its purpose in the present age altogether ill adapted for the objects of astronomy. Perrault died in 1688. Cotemporary with him was Le Mercier, the architect of the church de l'Oratoire, in the Rue St. Honoré. Le Mercier died, however, in 1660; eight and twenty years, therefore, before the decease of Perrault. Among the architects whose practice was exceedingly extended was Jules Hardouin Mansart, the architect of Versailles, and the especial favourite of Louis XIV. He was principally employed between the years 1675 and his death in 1708. His ability, as Milizia observes, was not equal to the size of his edifices; though it is hardly fair for that author to have made such an observation on the architect of the cupola of the Invalides at Paris. Of this church and dome De Quincy has most truly stated, that though nothing that can be called classic is to be noticed about it, yet it contains nothing in dissonance with the principles of the art. It is a whole in which richness and elegance are combined; in which lightness and solidity are well balanced; in which unity is not injured by variety; and whose general effect silences the critic, however he may be disposed to find fault. In Versailles, the taste which we have above noticed as introduced by De Brosse is prevalent; but the interior of the chapel displays to great advantage the great genius of Mansart, and that he was not incapable of the most refined elegance.

360. Jacques Ange Gabriel was the relation and worthy pupil of Mansart. The colonnades to the Garde Meuble in the Place Louis XV. (now the Place de la Concorde) exhibit a style which, with the only exception of Perrault's façade of the Louvre, not all the patronage of Louis XIV. was capable of eliciting. To Gabriel almost, if not perhaps as much as to Perrault, the nation is under a debt of gratitude for the confirmation of good taste in France. He has been accused of pirating the Louvre; but reflection and comparison will show that there is no real ground for such an accusation. The difference between the two works is extremely wide. The basement of Perrault is a wall pierced with windows; that of Gabriel is an arcade: in the upper stories the columns are not coupled, which is the case at the Louvre. From these circumstances alone the character of the two works is so different, that it is quite unnecessary to enter into other detail. Architecture in France at this period, the commencement of the eighteenth century, was in a palmy state, and has never before or since risen to higher excellence; though the French are still, from the superior method of cultivating the art there, and the great encouragement it receives, the first architects in Europe. The great extent of the Place Louis XV. (744 ft. long, and 522 broad) is injurious to the effect of the Garde Meuble, which, as the reader will recollect, is rather two palaces than one. Its basement is perhaps, speaking without reference to the vast area in front of it, too high, and the intercolumniations too wide, for the order (Corinthian) employed; but it is easier to find fault than to do equally well; and we cannot leave the subject without a declaration that we never pass away from its beauties without a wish to return and contemplate their extreme elegance. They are to us of that class to which Cicero's expression may be well applied: "pernoctant nobiscum, peregrinantur." Gabriel died in 1742. Antoine, the architect of the Mint at Paris, was another of the choice spirits of the period: he continued the refined style whereof we are speaking; and though the age of Louis XV. was not destined to witness the erection of such stupendous edifices as that of Louis le Grand, it displayed a purer and far better taste. This architect was the first who employed in his country the Grecian Doric, which had then become known, though not perfectly, by the work of Le Roy. Antoine used it at *L'Hospice de la Charité*; and De Quincy cites it as a circumstance which called forth the approbation of people of taste, and observes that the attempt would have attracted more followers, if, instead of exciting the emulation of architects in the study of it and its judicious application to monuments, to which the character of the order is suitable, fashion had not applied it to the most vulgar and insignificant purposes. Antoine lived into the present century, having died in 1801, at the age of 68.

361. Louis XV., during a dangerous illness at Metz, is reported to have made a vow which led to the erection of the celebrated church of St. Geneviève, or, as it has since been called, the Pantheon: the largest modern church in France, and second to none in simplicity,

elegance, and variety. Another cause may, however, with as much probability, be assigned; the inadequacy of accommodation for the religious wants of the population, and especially of that appertaining to the patroness Saint of Paris. Many projects had been presented

PLAN OF PANTHEON, PARIS.

Fig. 178.

ELEVATION AND SECTION OF PANTHEON, PARIS.

for the purpose, but that of Soufflot received the preference. This talented artist, who was born in 1713, at Irancy near Auxerre, after passing some time in Italy, had been settled at Lyons, and there met with considerable and deserved employment. In that city the great hospital had deservedly brought him into notice, for his knowledge in providing against the miseries of mankind, not less than had his beautiful theatre for providing for its pleasures. The plan (*fig. 177.*) of the Pantheon (so it is now usually called) is a species of Greek cross. The interior is divided transversely into two equal parts on each side, and a central one much larger, by isolated columns, instead of the plans previously in use of arcades decorated with pilasters. It is, however, strictly, in its internal as well as external character, to be classed as belonging to the Venetian school. Its west front and transverse section are given in *fig. 178.* The light effect, which is so striking in the interior, produced by the employment of columns instead of the old system of arcades, is extremely pleasing, though, as has often been truly urged, they have no office to perform. Objections, moreover, have been taken to the wide intercolumniations of the portico, and to some other parts, which here it is unnecessary to particularise. It is, notwithstanding all that has been written against it, most certainly entitled to take the fourth place of the modern great churches in Europe; which are, Santa Maria del Fiore at Florence, St. Peter's at Rome, St. Paul's at London, and then the church in question. Its greatest fault is instability about the piers of the cupola,—the old fault, from which not one is altogether free, and one which gave Soufflot so much uneasiness that it is said to have hastened his death. This failure was afterwards rectified by his celebrated pupil Rondelet, who, with consummate skill, imparted perfect and lasting security to the edifice.

362. We ought perhaps before to have mentioned the name of Servandoni, as eminently influencing, in his day, the taste of Paris, which, as the world knows, is that of France. A Florentine by birth, and a scholar of the celebrated Pannini, he, in 1731, exhibited a model for the façade of St. Sulpice; and after a year's probation before the public, it was adopted. On an extended front of 196 ft. he succeeded in imparting to it, as a whole, an air of great majesty, and of giving to the church a porch of vast extent without injury to the general effect. Servandoni was very extensively employed: his style was that of the Venetian school; and his death occurred in 1766.

363. To write an history of the modern architecture of France, and at the same time to do its professors justice, would require a much larger volume than that under our pen: we profess to give no more than a bird's-eye view of it, so as to bring the reader generally acquainted with its progress; and it is not without much regret that we propose closing our account of it in the person of Jacques Gondouin, who died at Paris in 1818, at the age of eighty-one; an architect whose veneration for the works of Palladio was so unbounded, that for the study of them exclusively he performed a second journey into Italy: a strange infatuation in a man of great acquirements, if the opinions of some of our anonymous critics are of any value. When Gondouin was employed, the heavy style of Louis XIV. had passed away, and the suitable and elegant style of the Venetian school had been adopted. The pupils of Blondel, among whom he was eminent, were stimulated by the patronage of the whole capital; and even in the present day, so far capable are its inhabitants of appreciating the merits of an architect, regret as we may to record it, that it is from that circumstance alone likely to maintain its superiority over all others in Europe. The most celebrated work of Gondouin is the Ecole de Médecine, whose amphitheatre for lectures, capable of holding 1200 persons, is a model for all buildings of its class, without at all entering on the great merits of the other parts of the building. He was one of those upon whom the effects of the French Revolution fell with particular force, though, upon the re-establishment of order, he in some measure recovered his station in society. He was entrusted with the erection of the column in the Place Vendôme, but merely as respected its preparation for the sculpture.

464. In Paris is to be found some of the most beautiful street architecture in Europe. That of Rome and Florence is certainly of a very high class, and exhibits some examples which will probably never be equalled. These, moreover, have associations attached to them which spread a charm over their existence of which it is not easy to divest one's self, and which, perhaps, contain some of the ingredients which enter into our high admiration of them. But, on a great and general scale, the most beautiful street architecture in Europe is to be found in Paris; and so great in this respect do we consider that city, that we are certain the education of an architect is far from complete if he be not intimately acquainted with the examples it affords. In that, as in most of the cities of Europe, the requirements of the shopkeeper interfere with the first principles of the art; but in this the violation of the rules of sound building, so as to connect them with his accommodation, are less felt by the critical observer than elsewhere. The spirit which seems to actuate the French nation is to produce works which may properly be called *monumental*; in this country, the government has never applied itself to a single work worthy of that epithet. The principal care of an English minister seems to be that of keeping his place as long as the nation will endure him. Commerce and politics are the only subjects which such a personage

seems to think worthy his attention, and the sciences have only been patronised by the government in proportion to their bearing on those two absorbing points. But we shall perhaps revert to this in the following chapter.

## SECT. XVIII.

## GERMAN.

365. No country exhibits more early, beautiful, or interesting specimens of Romanesque and pointed architecture, than Germany. The Rhine, and the southern parts of it which were under the sway of the Romans, are those, as we have already observed, in which these are principally to be found. Their history, however, has, sufficiently for general purposes, been traced under the sections of Byzantine or Romanesque and Pointed Architecture. The revival of the arts in Italy, as it did in other nations, here equally brought in the styles of the Italian schools, which, as elsewhere throughout Europe, have lasted to the present period; and will certainly endure until some general change in the habits of its different nations renders necessary or justifies some other style as a worthy successor to them. On this to speculate were a waste of time; though there be some, and those men of talent, who contemplate a millennium of architecture, by making every thing in style dependent on the new materials (cast-iron for instance) which it is now the practice to employ, and often, it must be conceded, most usefully. Whilst the pointed style lasted in Europe, Italy was occasionally indebted to the Germans for an architect. Thus, notwithstanding the denial of Milizia, Lapo, a German architect, was employed in the early stages of construction of Santa Maria del Fiore; and it is well authenticated that Zamodia a German, Annex of Friburg, and Ulric of Ulm, were employed on the cathedral at Milan. Franchetti (*Storia e Descrizione del Duomo di Milano*, 4to. Milan, 1821) asserts, that the first of these was engaged on it about 1391, the period of the golden age of pointed architecture in Germany; and the reputation of the Germans in this respect was at that time so great, that John and Simon of Cologne were actually carried into Spain for the purpose of designing and carrying into execution the cathedral at Burgos. It is at this period difficult to assign the cause of the nation so completely dropping astern, to use a nautical phrase, in the fine arts, and more particularly architecture. It was most probably the result of their political condition, and the consequent relative position they occupied in the affairs of Europe. But, whatever the cause, it is, in fact, most certain, that from the revival of the arts in Italy until near the end of the 18th century, Germany furnishes the names of few, if any, architects who are known beyond the limits of the country. Italy during the time in question seems to have repaid the nation for the early assistance received from them. At Fulda and Vienna, Carlo Fontana was extensively engaged; Guarini on the church of Santa Anna at Prague; Scamozzi on the cathedral at Salzburg; Andrew Pozzo, who died at Vienna in 1709, was there employed on several of the churches: Martinelli of Lucca was another of the number that were solicited to decorate the country with their works. Fischers, indeed, was a native; but his works, and especially his palace at Schönbrun, begun in 1696 for the Emperor Joseph, though not altogether without merit, is but a repetition of the extravagances of the school of Borromini; and equally so was the palace built by the same artist for Prince Eugene at Vienna, in 1711. (*Essai d'Architecture Historique*, Leipsig, 1725.) Pietro Cart, who built the bridge at Nuremberg, Neuman, Bott, and Eosander of Prussia, are the only native architects of the period recorded by Milizia.

366. But it was not only from Italy that the Germans drew their architects: France contributed a supply to the country in the persons of Blondel, who was there much employed towards the end of the 17th century; Robert de Cotte and Boffrand in the first part of that following. It is therefore, from what has been stated, impossible to give any independent account of the architecture of Germany. The Germans had none. Whoso were their architects, they were the followers of a style which contemporaneously existed in France and Italy even down to the bizarreries of that which prevailed in the time of Louis XV.; and it is a very curious fact, that whilst Germany was seeking the aid of architects from France and Italy, England could boast of professors of the art whose fame will endure while printing remains to spread knowledge amongst mankind. During the last century, Germany appears to have risen in this respect from its slumber, and to have produced some men of considerable architectural abilities. Of these was Carl Gotthard Langhans, who was born in 1732, and built the celebrated Brandenburg gate at Berlin, which, though formed much on the model of the Propylea at Athens, and therefore on the score of originality not entitled to that praise which has been so unsparingly exhausted upon it, proves that a vast change had begun in Germany as respected matters of taste in ar-

chitecture. Copies prove sad poverty of imagination on the part of the artist copying; and all, therefore, that can be said in favour of such an expedient as that under consideration is, that better forms being submitted in this example to the Germans, it created a dawn of taste to which they had long been strangers. The inaccurate work of Le Roy, which had preceded that of Stuart and Revett on the antiquities of Athens, was the means through which Langhans wrought and tried his successful experiment. In France, as we have already observed, Antoine had tried the employment of the Grecian Doric at Paris, but without the impression produced by Langhans. This architect died at Berlin in 1808, and is, perhaps, entitled to be considered as the father of good architecture in Germany, where he met the highest patronage and encouragement. Knoblesdorff, who died in 1753, had, it must be allowed, prepared in some measure the change which was effected; but neither he nor his successor are known in the world of art beyond the confines of their own country. The names of Boumann, Goutard, Naumann, and others of much merit, occur to us; but the examples which they have left are not of the class that justify specimens for presentation to the reader in a general work of this nature. None of them rise so high as to be put in competition with the examples of the French school; and from the circumstance of the principal works of Germany at Munich, Berlin, &c. having been executed by artists still living, we feel precluded here from allusion to them; because, if we were to enter on an examination of them, we must detail their defects as well as their beauties. An extraordinary species of bigotry has laid hold on some in relation to them, which time will temper; and the world, as it always does, will ultimately come to a right judgment of the rank they are entitled to occupy as works of art. In the other branches of the arts the Germans are rising fast; but there is withal an affectation of the works of the middle ages in their productions, which, impressed as they are with great beauties, are not sufficiently pure to prognosticate the establishment of schools which will sweep all before them, as did those of Italy.

## SECT. XIX.

### SPAIN AND PORTUGAL.

367. What has been said in the preceding section on the architecture of Germany is equally applicable to that of Spain and Portugal, whose architects were educated, if not in the schools of Italy, yet on the principles that guided them. Still, the pre-eminence in architecture on the revival of the arts must be given to these countries over the contemporaneous buildings erected in Germany, and more especially to those of Spain. Under Ferdinand and Isabella, both greatly attached to the fine arts, the pointed style gave way to the architecture then in esteem in Italy; and Giovanni de Olotzaga, a native of Biscay, is, we believe, entitled to the merit of having first introduced it in the great college of Santa Croce at Valladolid, which was commenced in 1480, and finished in 1492. About the same period appeared Pietro de Gumiel, supposed to have been the architect of Santa Engracia at Saragossa; but known as the artist who designed the college of Alcala, a splendid building in a mixed and impure style. In this the orders were employed. The edifice consists of three courts: the first Doric, with an arcade and two orders above, in the lower whereof the Doric was repeated, and the upper was Ionic; the second court has thirty-two Composite columns, with arcades; and the third is designed with thirty-six Ionic columns, beyond which is the theatre. The church is of the Ionic order, and contains the monument of Cardinal Ximenes, the founder, considered one of the finest in Spain. The names of Giovanni, Alonso, and Fra Giovanni d'Escobado continue in their works the history of the art in Spain, wherein a style between the pointed and Italian prevailed during the greater part of the reign of Charles V. Giovanni Gil de Hontanón, at the end of the 15th century, appears in Spain as an architect of much celebrity. He made a design for the cathedral at Salamanca, which was submitted to the judgment of four of the then most eminent architects of the country,—Alonso de Cobarrubias, the architect of the church at Toledo; Mastro Filippo of that of Seville; Giovanni di Badajos of that of Burgos; and Giovanni Balleo, by whom Hontanón's design was approved and commended. This church is 378 ft. long, and has a nave and two series of aisles on each side. The nave is 130 ft. high, and 50 ft. wide. Rodrigo Gil, son of the above-named architect, had the execution of this church, which commenced in 1513. It was probably this Rodrigo who, in 1525, erected the church of Segovia, very similar to that of Salamanca, except that it is more simple, and in a purer style. The cathedral of Segovia, equal in size and grandeur to those of Toledo and Seville, was, after 1577, carried on by Francesco de Campo Aguero, who died in 1660; to whom succeeded Biadero, who died in 1678. Respecting Hontanón, Don Ant. Ponz observes, in the 10th volume of his *Travels in Spain*, that he must have been a clever architect, and well acquainted with the Greek and

Roman styles, which in his time were beginning to revive ; but that, like many other artists, he was obliged in some measure to humour the taste of those who employed him : he therefore adopted the Gothic style, without the ornaments and details. The efforts of the architects of this period were not confined altogether to church building ; for in 1552 Pietro de Uria constructed a bridge at Almaraz over the Tagus, which may vie with the most extraordinary works of that class. Two large pointed arches form the bridge, which is 580 ft. long, 25 ft. wide, and 134 ft. high. The opening of one of the arches is 150 ft., that of the other 119 ft. The piers are lofty towers, that in the centre standing on a high rock. Another pier has a semicircular projection between the arches, forming a piazza at the top.

368. Alonzo de Cobarrubias, the architect of the church of Toledo, seems to have used in it a Gothic sort of style, though when he flourished the Roman orders had become known and used. This Alonzo was in considerable employ, as was his assistant, Diego Siloe, who built the church at Granada, with the monastery and church of San Girolamo in that city. This cathedral has a nave and two aisles ; and in it the Corinthian order, though defective in height, is used. The cupola is well designed. Both Siloe and his master loaded their buildings with sculptures to excess, from a seeming notion that beauty and richness were the same or inseparable. Alonzo Berruguette was another architect of the 16th century who was deservedly employed. He went to Italy in 1500, there to pursue his studies in the arts of painting and sculpture as well as architecture, and was at Florence when Michael Angelo and Leonardo da Vinci exhibited their cartoons. He was the architect of Charles V. ; and it is supposed that he designed the palace at Madrid, begun by Henry II., continued by Henry III., and splendidly rebuilt by Charles V., but no longer in existence. Berruguette erected the gate of San Martino, which is the principal one at Toledo. It is of the Doric order, with the royal arms on the exterior, and a statue of Santa Leocadia in the interior. There are great simplicity and elegance in the composition of this work. The palace of Alcala, the residence of the archbishop of Toledo, is attributed to him ; a building not wanting in magnificence, though defective in its detail. A great portion of the cathedral of Cuenca is said to be by Berruguette ; but not the façade, which was erected in 1699 by Guiseppe Arroyo, and afterwards continued by Luigi Arriaga. There is considerable effect about the cloister, which is well and ingeniously decorated. This architect, it is thought, had some part in the Pardo, which was rebuilt in 1547 ; where are still allowed to remain,—notwithstanding the additions by Philip II. of the miserable eastern and western façades—the porticoes of Ionic columns, with their low stone arches. Though the windows are greatly too far apart, and too small in the lower story, the stairs difficult of ascent, yet, upon the whole, the edifice is not ill arranged or executed. At the period whereof we here speak there was a prodigious passion among the Spaniards for large screens and altars in the churches ; in these the taste of Berruguette was most conspicuous. In the use of the orders, which he fully understood, he was remarkably fond of employing them over one another. The cathedral at Seville was principally rebuilt by Ferdinando Ruiz, who was much engaged in the city, and especially on enlarging or raising the well-known tower called the Giralda. This singular edifice was begun in the 11th century, the original idea of it being given by the architect Geber, a native of Seville, to whom the invention of algebra is attributed ; and also the design of two other similar towers, one in Morocco, and the other at Rabata. The tower of which we are now speaking was at first 250 ft. high, and 50 ft. wide, and was without diminution as it rose. The walls are 8 ft. thick of squared stones from the level of the pavement ; the rest for 87 ft. is of brick. In the centre of this tower is a smaller one, the interval between the two towers being 23 ft., which serves for the ascent, one so convenient that two persons abreast can mount it on horseback. The central tower does not diminish ; but as the edifice rises in height the walls gather over, so as to allow the passage of only one person. Upon the Moors of Seville negotiating their surrender, one of the conditions of it was, that this tower should not be destroyed ; to which Don Alphonso, the eldest son of the king, answered, that if a portion of it were touched, not a man in Seville should survive. In the earthquake of 1395 it was partially injured, and remained in the state of misfortune that then occurred until 1568, when, by the authorities, Ferdinando Ruiz received the commission to raise it 100 ft. higher. This height he divided into three parts, crowning it with a small cupola or lantern : the first division of his addition is of equal thickness with the tower on a plinth, whence six pilasters rise on each façade, between which are five windows, over which is an entablature surmounted by balustrades ; the second division is lower, with the same ornament ; and the third is octagonal with pilasters, over which the cupola rises, crowned with a bronze statue of Faith, vulgarly called “ La Giralda.” Ruiz by this work augmented his fame ; and notwithstanding the earthquakes which have since occurred, he has been fortunate enough to preserve it. We have, however, to apologise to our readers for this, which is anecdote, and not quite in order to be placed here, because partly connected with a period we have long since left. Pictorially speaking, the tower of the Giralda is a splendid object, and the

apology was, perhaps, unnecessary. The age of Charles V. in Spain was Augustan for its architecture. By his mandate the palace was raised at Granada, a work of Machuca, another architect of this period. The principal façade is rustic, with three large gates, and eight Doric columns on pedestals sculptured with historical bassi-relievi. The second story is Ionic with eight columns, over which are pilasters. The internal vestibule is on a circular plan, with a portico and gallery on columns of the same order. Milizia, from whom we have extracted all our notices on the architecture of Spain in this age, regrets that the arches spring from the columns. Though we cannot commend such a practice, we should be sorry, in certain cases, to see a veto put upon it; because the practice is occasionally compatible with fine effect.

369. Towards the end of the sixteenth century appears in Spain an artist, by name Domenico Testocopoli, by birth a Grecian, and a disciple of Tiziano Vecelli. He became, under his master, a good painter; but is known in Spain rather as a celebrated architect in his day. At Madrid, and in Toledo, he executed many works of merit; but his grand work was the church and monastery of the Bernardine monks of San Domingo di Silos, in which he employed his talents in architecture, painting, and sculpture, the whole being from his hand.

370. Garzia d'Emere and Bartolomeo di Bustamente, the latter especially, would require an extended notice in the history of the art in Spain, if our limits permitted us to enter on their merits. The latter was the architect of the hospital of San Giovanni Battista, founded by its archbishop in 1545, near Toledo. We should continue the account if works existed from which a feature different from the contemporaneous works in the rest of Europe could be extracted; but the fact is, that the progress of the art has already been told in other countries, and its success in Spain would be but a repetition in minor degree of what has already been said. Still we consider some notice must be taken of Giovanbattista di Toledo, who died in 1567, an architect and sculptor of surpassing merit; and as he was the architect who gave the designs for the façade of the Escorial, we shall not apologise for transcribing the account of him given by Milizia.

371. Having studied at Rome, he was invited to Naples by Don Pietro di Toledo, then viceroy there, who employed him as architect to the Emperor Charles V. in many important works in that city, whence he was called by Philip II. to become architect of all the royal works in Spain, and especially of the Escorial, which that monarch was anxious to erect in the most magnificent style. For this purpose he left Naples, and in 1563 commenced, upon his own design, the Escorial, which he continued to superintend till his death in 1567. In this great undertaking he was succeeded by Giovanni d'Herrera, his pupil, who finished it. Those, therefore, says the author whom we quote, that attribute this work to Luigi de Foix, to Bramante, to Vignola, and other architects who may have given designs for it, are unacquainted with the subject. The wonders related of the Escorial, as to the number of its doors and windows, are not tales to be here recounted; and the attempt, indeed, at exaggeration is vastly silly, because it is on so grand a scale that the simple truth imparts quite sufficient knowledge for conveying an idea of its splendour. The motives of Philip II. in founding this structure were twofold, — first, the injunction of his predecessor Charles V., who was desirous of constructing a tomb for the royal family of Spain; and secondly, of erecting an edifice of colossal dimensions to commemorate the famous victory of S. Quintin, achieved on the festival of San Lorenzo, the saint to whose interposition the king attributed his success. The situation chosen to receive it was beautiful. It is at the distance of a few miles from Madrid, at the foot of the Carpentani mountains, by which the two Castiles are divided. The plan of the edifice is said to resemble a gridiron, the instrument of martyrdom of Saint Lawrence, of which the handle is the projection in the eastern façade; we confess, however, we have some difficulty in tracing the resemblance. It is divided internally into fifteen courts, varying considerably in size; many of them are decorated with porticoes and galleries, and contain in all upwards of eighty fountains. The materials are granite very well wrought; the roofs partly covered with lead and partly with slate. The cupola of the church is stone. The four angles of the main plan are distinguished by towers rising four stories, besides those in the roofs, above the general fronts; besides which there are four others flanking the cupola. Parts of the building are in much better taste than others; but such an enormous pile of building cannot be otherwise than imposing, more especially, too, if there be anything like symmetry and regularity in the parts. Towards the west the principal façade is 740 feet long and 60 feet in height. The towers at the angles just mentioned rise to the height of 200 feet. This façade, like the others, has five stories of windows, which necessarily of themselves, from the way in which they are arranged, have the effect of cutting it up into minute divisions. The central compartment of it is 140 feet in length, and consists of two orders of half columns; the lower has eight semi-columns, which are Doric, standing on a plinth, and in the central intercolumniation is the door; the other intercolumniations are filled in with niches and windows in three stories. The upper order is of four Ionic columns on pedestals, which are surmounted by a pediment. This upper

order has two stories of niches in its intercolumniations, in the upper central one whereof is placed the statue of St. Lawrence. The two minor doors in this façade are also made features in the design. The façade towards the east has the projecting handle of the grid-iron to which we have alluded, in which part is contained the palace; and westward of it the great chapel or church, with its cupola rising above the mass, to complete the composition. Towards the south the length is 580 ft., similar to the length on the north. On entering from the central gate of the western façade, the monastery is divided from the college by a large vestibule, from which three large arched openings lead into the king's court: this is 230 ft. long, and 136 ft. wide, surrounded by buildings of five stories, and ornamented with pilasters. At the eastern end of this court is the entrance to the church, over whose vestibule or pronaos are the libraries. To it a flight of seven steps crosses the whole width of the court; and from the landing rises a Doric arcaded porch of five openings, three whereof belong to the central compartment and lead to the church, the other two leading to the monastery and the college. Behind the porch the façade of the church rises, and is flanked by two towers, which respectively belong to the monastery and college, and are ornamented above the general height of the buildings of the court with two orders of pilasters, being terminated by small cupolas. The interior of the church is Doric, and is in plan a Greek cross. The nave is 53 ft. and the aisles are 30 ft. wide. Its whole length is 364 ft., its width 230, and height 170. From the intersection of the nave and transepts the cupola rises, 66 ft. in diameter, and 330 ft. in height from the pavement to the cross. Its exterior is composed with a square *tambour* or drum, if it may be so called, from which the order rises. The choir is only 30 ft. high, and its length but 60 ft. In point of taste and dimensions, the church is inferior to several in other parts of Europe. The presbytery, we should have stated, is raised, so as to form almost another church, and seemingly without relation to the principal one. The staircase which leads to the Pantheon, and which possesses considerable magnificence, is placed between the church and the antechurch: we are not aware why this name has been given to the sepulchre of the kings of Spain. It is nearly under the high altar. The chamber appropriated to the reception of the kings is 36 ft. diameter, and 38 ft. in height, richly encrusted with various marbles and metals, and ornamented with sixteen double Corinthian pilasters on pedestals, arranged octagonally; and between them are recesses, with the sarcophagi, amounting to twenty-six, that is, four in each of six sides, and two over the entrance which faces the altar of the Resurrection. This is a fair specimen of the style which prevailed in Spain under the reigns of Philip IV. and Charles II. The college, the seminary, and the royal palace occupy the rest of the building. In 1773, many additions were made to the buildings about the Escorial for the Infants Don Antonio and Don Gabriele, by Villaneuva, an Italian architect, and by them the palace was much improved. Giovanni d'Herrera, who died in 1597, besides his employment at the building just described, contributed greatly to the advancement of the art by the execution of the many commissions with which he was entrusted. The bridge of Segovia, at Madrid, is by him; as is the royal pleasure-house at Aranjuez, begun under Philip II. and finished by Charles III., — a work which, though far from pure, exhibits great architectural ability. His successor at the Escorial was Francesco de Mora, by whom, at Madrid, is the Palace de los Consejos, the most splendid edifice which that capital can boast. Instead of a central doorway, it has two at its flanks, of the Doric order, with appropriate decorations. In the beginning of the seventeenth century, the great square of Madrid was erected after the designs of Giovanni Gomez de Mora, and is admirable for its grandeur and symmetry. This architect built at Alcalá the church and college of the Jesuits, which, Milizia says, is a magnificent and well-proportioned edifice. It is of two orders, and the material employed in the façade is granite. The royal convent of the Augustins, at Madrid, is also attributed to him.

372. In the beginning of the eighteenth century, Filippo Ivara, a native of Messina, had very great employ, we might almost say throughout Europe. He became the pupil of Fontana, and afterwards, on his visiting Spain, seems to have established a school there. He built the façade of the royal palace of St. Ildefonso, looking towards the gardens. Ivara died in 1735, at Madrid, whither he had been invited by Philip V. to rebuild the palace, which had been consumed by fire. The work was afterwards intrusted to Sacchetti, a pupil of Ivara. It is on a very large scale, and was most solidly constructed.

373. We have thought it necessary to give the above succinct account of the architecture of Spain, which did not, however, produce, after the revival of the arts in Europe, any works, except in respect of dimensions, comparable with those of Italy. The abuses in them are almost universally carried to an extent scarcely credible; it is, therefore, useless to refer the reader or student to them as models. It almost seems as if from Italy pure architecture had not had time to spread itself before it became tainted with the corruptions of Borromini; which, not only in Spain and Portugal, but throughout Germany, and even France, were diffused with incredible rapidity.

## SECT. XX.

## RUSSIAN ARCHITECTURE.

374. WE scarcely know whether we are justified in making a short section with this heading, inasmuch as there is not known to us, up to the end of the eighteenth century, the name of a single Russian architect. English, French, Italian, and German artists have been employed in the decoration of the city of Petersburg, though we believe that the nation is now beginning to produce persons capable of conducting their public works. Russia has received all its improvement from abroad, and has used every exertion to communicate it to an uncivilised people.

375. The ecclesiastical architecture of Russia is of course coeval with the introduction of Christianity into the country, which was not earlier than the time of Vladimir the Great, although the Princess Olga had been baptized at Constantinople as early as the year 964. Vladimir, to display his zeal in behalf of Christianity, had a church, supposed to be the first built by him, erected at Cherson; a year after which the church of St. Basil, which, as well as the first named, was of timber, was erected under his command. This prince also built a church at Kief, where, it is said, there were already at the time 500 churches. After Vladimir, Prince Yaroslav appears to have bestowed great attention on the erection of ecclesiastical edifices. At Kief he founded a church, dedicated to St. Sophia, and at Novogorod another to the same saint: these partly exist in the present day. By him also were reared the convents of St. George and St. Irene. The celebrated convent of Petchorsky, at Kief, was erected in 1075, subsequent to which period the Russian metropolitans continued subject to those of Constantinople till the capture of that city by Mahomet the Second. Between this last capital and Kief the bonds of amity of their rulers were drawn closer by many intermarriages; but in the year 1124 a fire desolated the latter city, which must have risen into great importance, inasmuch as 600 churches and monasteries were destroyed in the conflagration. Afterwards, again, in the civil war under Yislaslaf, Kief was taken and fired; a calamity to which it was again subject at the same period that Constantinople was taken by the Venetians. After this Kief never again recovered its ancient magnificence. In 1154, at which period Moscow is first mentioned in history, it was but an insignificant village. It received great additions under Daniel of Moscow; and in 1304, under John Danielowitz, it became the capital of the empire. On the 4th of August, 1326, the first stone was laid of a church in the Kremlin there in honour of the Assumption of the Virgin. The palace of the Kremlin was a timber structure until the reign of Demetri Donskoi, when it was reconstructed of stone. On the capture of Constantinople by Mahomet the Second, the Russian church ceased to be dependent on that of Constantinople. The palace of the Kremlin, known by the name of the granite palace, rose in 1487; and, in twelve years afterwards, the Belvedere palace was raised. Ivan IV., whose sway was of extended duration, was a great patron of the arts; his decease took place circa 1584. He renewed the laws relative to the paintings in the new churches, whence arises their so close resemblance to each other that it is difficult to judge of the epochs of their execution. The celebrated clock tower Ivan Valiki, at the Kremlin, was erected by the Czar Boris, in 1600, at which time Moscow contained 400 churches, whereof 35 stood in the Kremlin alone. After the time of Peter the Great, a change of style was introduced.

376. The Church of the Assumption above mentioned, as respects the plan, is an oblong square divided; the vaulting whereof is supported by six columns in the interior. Though at the first glance it be not perceived, the arrangement of the cupolas soon points to the form of a Greek cross. In the earlier churches the plan was a square, with a porch in front of it; but, in the Church of the Assumption, the porch is a portion of the church, the arches of the cupolas being placed in the same way as if the church were of the ancient form. The six columns just mentioned divide the church into four parts,—from east to west, and then from north to south. At the eastern sides are three apses, divided by the width of a column, the middle one being of larger dimensions than the other two; an arrangement which prevails in most of the Greek churches. The apses contain altars, which are frequent, except in the small chapels. The altar in the Greek church is not exposed to public view; it is concealed or covered by the iconostasis (image-bearer), a very large screen, which, from occupying the whole width of the church, divides it into two parts. This screen has a central principal and two side smaller doors; behind which latter, on each side, stands a second and smaller iconostasis, of the width only of the smaller apsis, but whose plan with three doors and an altar behind is similar to the great one. This was the distribution in the early churches; but, in the more modern ones, there are, at nearly the extremity of the edifice, three distinct iconostases. The place for the choristers is on each side in front of the iconostasis, between its principal and side doors. The principal cupola rises in front of the iconostasis; and, in cathedral churches, at the foot of the apsis on the left a canopy is placed for the emperor, opposite whereto is one for the metropolitan.

There is generally one principal and four subordinate cupolas round it, which stand on the four feet of the Greek cross. The iconostasis is a principal object in every church. It is usually in four or five horizontal compartments, each containing an unequal number of pictures of saints painted on tablets or long square panels, whose places are fixed with great precision. In the first story, if we may so call it, are the three doors; the centre one, being in two foldings, is decorated with the subject of the Annunciation, accompanied with the heads of the four Evangelists or their emblems. To the right of the door is a picture of Christ, and of the Madonna on the left. To the right of the Christ is the saint or festival of the church, after which the doors are inserted. Above the doors, on the left hand, is placed a Greek cross; on the right hand the cross of Moses, — as symbols of the Old and New Testaments. The paintings are all on a ground of gold. In the middle of the second story is Christ on a throne; on the right Saint John the Baptist; on the left the Madonna without Child; then, on each side, two archangels and six apostles. In the third story or horizontal compartment, the Madonna is introduced with the Infant on her knees, surrounded on each side by the prophets. In the fourth story is painted God the Father on a throne, with the Infant Jesus, surrounded on each side by patriarchs of the church. Occasionally a fifth story appears, upon which is painted the history or Passion of our Saviour. Paintings on a gold ground abound in the other parts of the church. The exteriors of these churches are extremely simple; cornices or other horizontal crownings are not to be found, but the coverings follow the cylindrical forms of the arches to which they are the extradoses, and are variously painted. The Russian churches built in the eleventh century, which from the number of their cupolas resemble, and indeed were imitated from those of the East, give a peculiar effect to the architecture. The forms of these cupolas are varied, but they generally stand on an octagonal *tambour*; some are hemispherical, others in curves of contrary flexure, and a number of other figures.

377. The type of the Russian church, which is on plan a Greek cross, is to be found in Santa Sophia at Constantinople. After the disputes between the Iconoclasts and Iconolaters, which, at the close of the seventh century, ended in the separation of the Eastern and Western churches, sculpture of statues disappeared from the Greek church, statues of angels excepted. Again, at this period, the altars on the side of the principal one were established, not, as in the Catholic churches, at the extremities of the transepts; their place is always in a niche or apsis. This arrangement is found in the churches of the eleventh, twelfth, and thirteenth centuries, at Bari, Trani, Malfetta, Otranto, &c., while the Greek worship existed; and a similar disposition is even seen at Palermo and other places where the worship has been Catholic. In the Catholic churches a sacristy, for the use of the priests in robing, &c., is always provided on the side of the church; in the Greek church, however, the priests robe themselves behind the iconostasis on the left of the altar, another altar being placed on the right for the consecration of the elements; and this arrangement exists in the present day. The Greek church has no gynæceum, or separate place for the women. — For the above we are indebted to the researches of M. Hallmann, an ingenious architect of Hanover.

378. It is in Saint Petersburg principally that we are to look for edifices which deserve mention. The foundation of the city was laid in 1703, by the Czar Peter, when he constructed a fort on an island in the Neva for defence against the Swedes. Buildings, both public and private, were soon erected; and the nobility and merchants being induced to settle there, the place quickly assumed the appearance of a considerable city. In the reigns of Catherine the Second and Alexander it reached a degree of great magnificence, from which it has not declined, but has rather advanced. Magnitude, rather than beauty of form, marks the public buildings of the city. The church of our Lady of Kevan is of great dimensions: for which, and its fifty-six granite columns with bronze capitals, it has obtained more celebrity than it will acquire for the beauty of its composition. Some of the palaces in the city are of colossal dimensions; that of Michailoff, built by Paul, is said to have cost ten millions of rubles. It was under the reign of Peter the Great that the great change took place in the national character of Russian church architecture by the introduction of the classical orders. The bulbous cupola, though at this period not entirely laid aside, fell into comparative disuse, being replaced by a green painted dome of which the Italian form was the model. The tasteless custom of painting the exteriors of buildings with bright and incongruous colours was retained; and, though well enough suited to the barbaric structures of the Muscovite czars, it ill accorded with the purer style of Italy. It is unnecessary further to detain the reader by any observations on the churches of the modern capital. In point of style or of history, they possess little or no interest for an English reader. To those who wish to become better acquainted with the architecture of Russia, we recommend a reference to Geissler's *Tableaux Pittoresques des Mœurs, &c. des Russes, Tartares, Mongoles, et autres Nations de l'Empire Russe*.

## CHAP. III.

## ARCHITECTURE OF BRITAIN.

## SECT. I.

## EARLY HOUSES AND ARCHITECTURE OF THE BRITONS.

379. On the invasion of Britain by Julius Cæsar, in the year 55 B. C., the inhabitants dwelt in houses resembling those of Gaul; and in Kent, and other southern parts of the island, their houses were more substantial and convenient than those in the north. Caves or earth houses seem to have been their original shelter; to which had preceded the wicker enclosure, whose sides were incrustated with clay. These were thatched with straw. The wooden houses of the ancient Gauls and Britons were circular, with high tapering roofs, at whose summit was an aperture for the admission of light and emission of smoke. These, where the edifices were grander than ordinary, were placed upon foundations of stone. There is no instruction to be derived from pursuing this subject further. That the arts at the period in question scarcely existed, is quite certain; and Caractacus may, when carried prisoner to Rome, have well expressed surprise that the Romans, who had such magnificent palaces of their own, should envy the wretched cabins of the Britons.

380. If the Britons were so uninformed in architecture as to be satisfied with such structures for their dwellings as we have named, it will hardly be contended that they were the builders of so stupendous a fabric as Stonehenge. On this subject we have already stated our opinion in Chap. II. From the distant period at which we believe this and similar edifices to have been erected up to that of which we are speaking many centuries must have elapsed, during which the mechanical knowledge which was employed in their erection might have been lost, and indeed must have been, from the condition of the inhabitants, of which mention has been made.

381. The Romans, after their invasion of the island, soon formed settlements and planted colonies; and it is not difficult to imagine the change which took place in its architecture. The first Roman colony was at Camalodunum. This, when it was afterwards destroyed by the Britons in the great revolt under Boadicea, appears to have been a large and well-built town, adorned with statues, temples, theatres, and other public edifices. (*Tacit. Annal.* lib. xiv. c. 32.) In the account given of the prodigies said to have happened at this place, and to have announced its approaching fall, it is mentioned that the statue of Victory fell down without any visible violence; in the hall of public business, the confused murmurs of strangers were perceived, and dismal howlings were heard in the theatre. At Camalodunum the temple of Claudius was large enough to contain the whole garrison, who, after the destruction of the town, took refuge in it; and so strong was it, that they were enabled to hold out therein against the whole British army for a period of two days. London, however, exhibited a more striking example of the rapid progress of Roman architecture in Britain. At the time of the first Roman invasion it was little more than a British town or enclosed forest; and there seems to be ground for supposing that at the time of the second invasion, under Claudius, it was not much improved. But when, about sixteen years afterwards, it came into the possession of the Romans, it became a rich, populous, and beautiful city. Not only did the Romans raise a vast number of solid and magnificent structures for their own accommodation, but they taught the arts to the Britons, and thus civilised them. Agricola, of all the Roman governors, took means for that purpose. That they might become less and less attached to a roaming and unsettled life, and accustomed to a more agreeable mode of living, he took all opportunities of rendering them assistance in erecting houses and temples, and other public buildings. He did all in his power to excite an emulation amongst them; so that at last they were not content without structures for ornament and pleasure, such as baths, porticoes, galleries, banqueting houses, &c. From this time (A. D. 80) up “to the middle of the fourth century,” says Henry (*Hist. of England*), “architecture, and all the arts immediately connected with it, greatly flourished in this island; and the same taste for erecting solid, convenient, and beautiful buildings which had long prevailed in Italy, was introduced into Britain. Every Roman colony and free city (of which there was a great number in this country) was a little Rome, encompassed with strong walls, adorned with temples, palaces, courts, halls, basilicæ, baths, markets, aqueducts, and many other fine buildings both for use and ornament. The country every where abounded with well-built villages, towns, forts, and stations; and the whole was defended by that high and strong wall, with its many towers and castles, which reached from the mouth of the river Tyne on the east to the Solway Firth on the west.

This spirit of building, which was introduced and encouraged by the Romans, so much improved the taste and increased the number of the British builders, that in the third century this island was famous for the great number and excellence of its architects and artificers. When the Emperor Constantius, father of Constantine the Great, rebuilt the city of Autun in Gaul, A. D. 296, he was chiefly furnished with workmen from Britain, which (says Eumenius) very much abounded with the best artificers. It was about the end of the third century that in Britain, as well as all the other provinces of the Western empire, architecture began to decline. It may have been that the building of Constantinople drew off the best artists; or that the time left for the peaceful culture of the arts may have been broken in upon by the irruptions of invaders from the north. According to the Venerable Bede (*Hist. Eccles.*, lib. i. c. 12.), the Britons had become so ignorant of the art before the final departure of the Romans that they, from want of masons, repaired the wall between the Forth and Clyde with sods instead of stone. Henry observes, however, on this, that "we cannot lay much stress on this testimony; because it does not refer to the provincial Britons, but to those who lived beyond the Wall of Severus, where the Roman arts never much prevailed; and because the true reason of their repairing that wall with turf, and not with stone, was that it had been originally built in that manner. Besides, we are told by the same writer, in the same place, that the provincial Britons, some time after this, with the assistance of one Roman legion, built a wall of solid stone, 8 ft. thick and 12 ft. high, from sea to sea."

382. The departure of the Romans, and that of the fine arts which they had introduced, were occurrences of almost the same date. We must, however, recollect that architecture was beginning to decline at Rome itself before the departure in question. The inhabitants of the country who remained after the Romans were gone had not the skill nor courage

to defend the works with which the Romans had provided them; and their towns and cities, therefore, were seized by invaders, who plundered and destroyed them, throwing down the noble structures with which the art and industry of the Romans had adorned the country. The vestiges of Roman architecture still remaining in Britain are pretty numerous; but scarcely any of them are of sufficient interest to be considered as studies of Roman architecture. Even in its best days, nobody would study the works of

Fig. 179. ROMAN WALL, LEICESTER.

art in the colonies in preference to those in the parent state. We have here (*fig. 179.*) inserted a representation of a small portion of the Roman wall at Leicester, as an example of the construction. Temples, baths, and villas of the time have, moreover, been brought to light not unfrequently.

383. The arrival of the Saxons in this country, A. D. 449, soon extinguished the very little that remained of the arts in the island. This people were totally ignorant of art; like the other nations of Germany, they had been accustomed to live in wretched hovels formed out of the earth, or built of wood, and covered with reeds, straw, or the branches of trees. It was not, indeed, until 200 years after their arrival that stone was employed by them for their buildings. Their cathedrals were built of timber. The Venerable Bede says there was a time when not a stone church existed in all the land; the custom being to build them of wood. Finan, the second bishop of Lindisfarne, or Holy Island, built a church in that island, A. D. 652, for a cathedral, which yet was not of stone, but of wood, and covered with reeds; and so it continued till Eadbert, the successor of St. Cuthbert, and seventh bishop of Lindisfarne, took away the reeds, and covered it all over, both roof and walls, with sheets of lead. Of similar materials was the original cathedral at York, a church of stone being a very rare production, and usually dignified with some special historical record. Bede, for instance, says of Paulinus, the first bishop of York, that he built a church of stone in the city of Lincoln, whose walls were standing when he wrote, though the roof had fallen down. Scotland, at the beginning of the eighth century, does not seem to have had a single church of stone. Naitan, king of the Picts, in his letter to Ceolfred, abbot of Weremouth, A. D. 710, intreats that some masons may be sent him to build a church of stone in his kingdom, in imitation of the Romans.

384. We here think it necessary to notice that we have thought proper, under this chapter, to preserve the periods, or rather styles of the periods of architecture, according to their ordinary arrangement in English works, namely, the Anglo-Saxon and Norman, in distinct sections. It is a matter of little importance to the reader how he acquires his knowledge, so that his author do not unnecessarily prolong the acquisition of it. Though, therefore, the Anglo-Saxon and Norman architecture are neither of them any thing more than Romanesque or Byzantine, to which we have appropriated rather a long section, we have here separated them into two distinct periods.

385. About the end of the seventh century masonry was once more, as well as some other arts connected with it, restored to England, by the exertions of Wilfrid, bishop of York, and afterwards of Hexham, and of Benedict Biscop, the founder of the abbey of Weremouth. The former, who was an indefatigable builder, and one of the most munificent prelates of the seventh century, erected edifices, which were the admiration of the age, at Ripon, York, and Hexham. The cathedral of the latter place obtained great celebrity. Eddius, speaking of it (*Vita Wilfridi*), says, that Wilfrid, having obtained a plot of ground at the place from Queen Etheldreda, he there founded a very magnificent church, and dedicated it to the blessed apostle St. Andrew. The plan of this holy structure appears to have been inspired by the Spirit of God; a genius, therefore, superior to mine is wanting to describe it properly. Large and strong were the subterraneous buildings, and constructed of the finest polished stones. How magnificent is the superstructure, with its lofty roof resting on many pillars, its long and lofty walls, its sublime towers, and winding stairs! To sum all up, there is not on this side of the Alps so great and beautiful a work. Biscop was a zealous cotemporary and companion of Wilfrid, and had also a great love for the arts. He travelled into Italy no less than six times, chiefly for the purpose of collecting books and works of art, and of endeavouring to induce workmen to come over to England. An estate of some extent having been obtained by him from Ecgrif, king of Northumberland, near the mouth of the river Were, he founded a monastery there in 674. Relative to this monastery of Weremouth, thus writes Bede: — “About a year after laying the foundations, Benedict passed over into France, and there collected a number of masons, whom he brought over with him to build the church of his monastery of stone, *after the Roman manner*, whereof he was a vast admirer. Such was his love for the apostle Peter, to whom the church was to be dedicated, that he stimulated the workmen so as to have mass celebrated in it but a little more than a year from its foundation. When the work was well advanced, he sent agents into France for the purpose of procuring, if possible, glass manufacturers, who at that time were not to be found in England, and of bringing them over to glaze the windows of his monastery and church. His agents were successful, having induced several artisans to accompany them. These not only executed the work assigned to them by Benedict, but gave instructions to the English in the art of making glass for windows, lamps, and other uses.”

386. The Bishop Wilfrid, as we learn from William of Malmesbury, with the assistance of the artificers that had been brought over, effected great reparations in the cathedral at York, which was in a decayed and ruinous state. He restored the roof, and covered it with lead, cleansed and whited the walls, and put glass into the windows; for, before he had introduced the glass makers, the windows of private dwellings as well as churches were filled with linen cloth, or with wooden lattices. It will be observed that the improvements we here mention were introduced by the bishops Wilfrid and Biscop towards the end of the seventh century; but, from our ancient historians, it would appear that, in the eighth and ninth centuries, stone buildings were rarely met with, and, when erected, were objects of great admiration. The historian Henry observes, that “when Alfred, towards the end of the ninth century, formed the design of rebuilding his ruined cities, churches, and monasteries, and of adorning his buildings with more magnificent structures, he was obliged to bring many of his artificers from foreign countries. Of these (as we are told by his friend Aperijs) he had an almost innumerable multitude, collected from different nations; many of them the most excellent in their several arts. Nor is it the least praise of this illustrious prince, that he was the greatest builder and the best architect of the age in which he flourished.” His historian, who was an eyewitness of his works, speaks in the following strain of admiration of the number of his buildings, “What shall I say of the towns and cities which he repaired, and of others which he built from the foundation?” Henry continues, — “Some of his buildings were also magnificent for that age, and of a new and singular construction; particularly the monastery of Æthelingay. The church, however, was built only of wood; and it seems probable that Alfred’s buildings were, in general, more remarkable for their number and utility than for their grandeur; for there is sufficient evidence that, long after his time, almost all the houses in England, and the far greatest part of the monasteries and churches, were very mean buildings, constructed of wood and covered with thatch. Edgar the Peaceable, who flourished after the middle of the tenth century, observed (see *William Malms. lib. ii. p. 32.*) that, at his accession to the throne, all the monasteries of England were in a ruinous condition, and consisted only

of rotten boards." The taste, however, of the Anglo-Saxons was not indulged in magnificent buildings; and the incursions of the Danes, who destroyed wherever they came, together with the unsettled state of the country, may account for their revenues being expended on mean and inconvenient houses.

387. Under the circumstances mentioned, it may be safely inferred that the art was not in a very flourishing state in the other parts of the island. Indeed, the ancient Britons, after retiring to the mountains of Wales, appear to have lost it altogether; and, as the Honourable Daines Barrington (*Archæologia*) has thought, it is very probable that few, if any, stone buildings existed in Wales previous to the time of Edward I. The chief palace, called the *White Palace*, of the kings of Wales, was constructed with white wands, whose bark was peeled off, whence its name was derived; and the price or penalty, by the laws of the country, for destroying the king's hall or palace, with its adjacent dormitory, kitchen, chapel, granary, bakehouse, storehouse, stable, and doghouse, was five pounds and eighty pence, equal, in quantity of silver, to sixteen pounds of our money, or 160*l.* The castles appear also to have been built of timber; for the vassals, upon whom fell the labour of building them, were required to bring with them no other tool than an axe.

388. Neither do the arts of building appear to have been better understood in Scotland at the former part of the period whereof we are speaking. The church built at Lindisfarne by its second bishop, Finan, in 652, was of wood, — *more Scotorum*; and it has already been mentioned that, for the stone church which Naitan, king of the Picts, built in 710, he was under the necessity of procuring his masons from Northumberland. In Scotland, there are still to be seen some stone buildings of very high antiquity, which Dr. Henry seems inclined to attribute to this period; we, however, are inclined to place them in an age far anterior, later (but not much so) than Stonehenge. We have never seen them, and therefore form our opinion from the description given in Gordon's *Itinerarium Septentrionale*. These buildings are all circular, though of two different kinds, so different from each other that they seem to be the works of different ages and of different nations. The four principal ones are in a valley, called Glenbeg. Of a different period, too, we consider the circular towers which are found as well in Scotland as in Ireland. It is true that in both countries these are found in the neighbourhood of churches; but that does not the more convince us that they were connected with them.

389. Ducarel, in his *Norman Antiquities*, enumerates some of the churches in England which belong to the ages anterior to the Norman conquest.

Fig. 180.

BARFRETON CHURCH.

Among them are those of Stukely in Buckinghamshire, Barfreton (*fig. 180.*) in Kent, and Avington in Berkshire. Other examples exist in Waltham Abbey; the transept arches at Southwell, Nottinghamshire; the nave of the abbey church of St. Alban's, Herts; the nave of St. Frideswide, Oxford, &c. &c. The Anglo-Saxon era, though it perhaps, properly comprised the time between A. D. 600 to A. D. 1066; that is from the conversion of the Saxons to the Norman conquest, is not known with any thing approaching to certainty, from the reign of Edgar in 980 to the last-named event; immediately previous to which Edward the Confessor had, during his lifetime, completed Westminster Abbey in a style then prevalent in Normandy, and with a magnificence far exceeding any other then extant. No less than eighteen of the larger monasteries, all of them Benedictine, had been founded by the Saxon kings in

their successive reigns; and it is evident that the churches attached to them were the most decorated parts, as respected their architecture. The six principal of these were, St.

Fig. 181.

SAXON ARCH.

Germain's, in Cornwall; Colchester, in Essex; Tewkesbury, in Gloucestershire; St. Frideswide and St. Alban's, already mentioned; and Glastonbury, in Somersetshire. King selects the western portion of Tewkesbury as the grandest in England for effect and extent. The characteristics of *Anglo-Saxon Architecture* are detailed in the following subsection.

390. *Arches*. — Always semicircular, often plain; sometimes decorated with a variety of mouldings on the soffit as

well as on the face, the former being often entirely occupied by them. They are found double, triple, or quadruple, each springing from two columns, and generally cased with a

Fig. 182. ARCH, CONVENTUAL CHURCH, ELY.

without any buttresses externally. — Almost always open timbering.

different moulding, which is frequently double, thus making six or eight concentric circles of them; and as each of them projects beyond that under it, a moulding is placed under them, generally the same as that used upon the face. (See fig. 181.) *Columns*. — Single, cylindrical, hexagonal or octagonal, on square plinths; very few diameters in height. Shafts often ornamented with spiral or fluted carving, with lozenge, herring-bone, zigzag, or hatched work. (Fig. 182.) *Capitals*. — Indented with fissures of different lengths and forms, and in different directions. The divisions thus formed are variously sloped off, or hollowed out towards the top. (See the two examples, fig. 183., from the conventual church at Ely.) Occasionally the capitals have rude imitations of some member of a Grecian order, as in the crypt at Lastringham in Yorkshire, where volutes are used. (Fig. 184.) In their ornaments much variety is displayed, but the opposite ones are mostly alike.

*Windows*. — Semicircular-headed, extremely narrow in proportion to their height, being sometimes not more than six or eight inches wide to a height of more than three feet, and splayed or bevelled off on the inside through the whole thickness of the wall. *Walls*. — Of very great thickness, and Masonry of solid construction. *Ceilings and Roofs*. In crypts, as at York, Winchester, and a few other

Fig. 183. TWO CAPITALS, CONVENTUAL CHURCH, ELY.

Fig. 184. CAPITAL FROM LASTRINGHAM

places, vaulting is to be found. *Ornaments*, except in capitals, in arches and on shafts of columns are very sparingly employed. (See Norman Ornaments also, in the following section on Norman Architecture, subsect. 397.) *Plans*. — Rectangular and parallelogrammic; being usually divided into a body and chancel, separated by an ornamented arch. The *chancel* sometimes of equal, and sometimes of less breadth than

the nave, and terminated towards the east in a semicircle. In larger churches, there is a nave and two side aisles, the latter being divided from the former by ranks of columns; but no transepts appear till towards the latter part of the period. "Whether," observes Mr. Millers, in his account of Ely Cathedral, whose system we adopt, "their churches were ever higher than one tier of arches and a range of windows above (as at Ely), may be questioned. Richard, prior of Hexham, speaks of three stories, which implies another tier of arches; but if he is rightly so understood, this seems an exception from a general rule, for the church at Hexham is spoken of by all writers who mention it, as the glory of Saxon churches in the seventh century. Afterwards, about 970, a considerable change took place; transepts came into general use, with a square tower at the intersection, rising but little above the roof, and chiefly used as a lantern to give light to that part of the church. Towers were also erected at the west end: the use of them coincides with the introduction of bells, at least of large and heavy ones." The churches of this period were of small dimensions, and the comparative sizes of the Saxon and the Norman churches which followed is almost a criterion for their age.

391. King (*Munimenta Antiqua*, vol. iv. p. 240.) gives three æras of the Saxon style. 1. From Egbert, 598 to 872. 2. From Alfred to Canute and Harold, 1036. 3. To the Norman conquest. He selects no less than thirty-seven examples of Saxon ornaments from mouldings on doorways only. As examples of the periods he adduces, of the *first*, *Barfreston* in Kent; of the *second*, the nave and choir of *Christ Church Cathedral*, Oxford, and Canute's great entrance gate at *St. Edmundsbury*; of the *third*, *Southwell*, Notts, and *Waltham Abbey*, Essex. It has been questioned by antiquaries whether any Saxon remains actually exist in the country; but, admitting their arguments, which are founded on references to records — no mean authorities, — it must be recollected that, on their own showing, some of these trench so close upon the period of the Conquest as to show that the Saxon style might have prevailed in them, for the general change of style in any art is not effected in a day. If we look for examples coeval with the Saxons themselves, and without controversy to be attributed to them, they will, perhaps, be found only in crypts and baptismal fonts; for many churches were rebuilt by the Normans, who left these parts untouched. The castles of Roman or Saxon foundation were, *Richborough*, in Kent; *Castletown*, in Derbyshire; *Porchester*, in Hampshire; *Pevensay*, in Sussex; *Castor*, in Norfolk; *Burgh*, in Suffolk; *Chesterford*, in Essex; *Corfe*, Dorset; *Exeter Castle gateway*; *Dover*, in Kent; and *Beeston*, in Cheshire.

## SECT. II.

### NORMAN ARCHITECTURE.

392. From the landing of William in 1066, architecture received an impulse, indicated in various styles, which lasted till the time of the Tudors; when, as we shall hereafter see, it gave way to one altogether different. That called the Norman style, which continued from 1066 to nearly 1200, comprised the reigns of William I., William II., Henry I., Stephen, Henry II., and Richard I. The twelfth century exhibited a rage for building in Britain more violent than has been since seen. The vast and general improvements that were introduced into fabrics and churches in the first years of this century are thus described by a contemporary writer (*Orderic. Vital. Hist. Eccles.*, lib. x. p. 788.): — "The cathedrals, and abundance of churches, newly built in all parts of the country, the great number of splendid cloisters and monasteries, and other residences for monks, that were there raised, sufficiently prove the happiness of England under the reign of Henry I. Peace and prosperity were enjoyed by the religious of all orders, who lent their whole power to increase the magnificence and splendour of divine worship. The ardent zeal of the faithful prompted them to rebuild their houses, and especially their churches, in a more suitable manner. Thus the ancient edifices raised in the days of Edgar, Edward, and other Christian kings, were taken down, and others of greater magnitude, beauty, and more elegant workmanship, were reared in their stead to the glory of God." As an example of the fervour with which these objects were carried into effect, we cite the following instance, quoting from Dr. Henry, upon whom we have drawn, and shall draw, rather largely. "When Joffred, abbot of Croyland, resolved to rebuild the church of his monastery in a most magnificent manner (A.D. 1106), he obtained from the archbishops of Canterbury and York a bull dispensing with the third part of all penances for sin to those who contributed any thing towards the building of that church. This bull was directed not only to the king and people of England, but to the kings of France and Scotland, and to all other kings, earls, barons, archbishops, bishops, abbots, priors, rectors, presbyters, and clerks, and to all true believers in Christ, rich and poor, in all Christian kingdoms. To make the best use of

this bull, he sent two of his most eloquent monks to proclaim it over all France and Flanders; two other monks into Scotland; two into Denmark and Norway; two into Wales, Cornwall, and Ireland; and others into different parts of England. By this means (says the historian) the wonderful benefits granted to the contributors to the building of this church were published to the very ends of the earth; and great heaps of treasure, and masses of yellow metal, flowed in from all countries upon the venerable abbot Joffred, and encouraged him to lay the foundations of his church. Having spent about four years in collecting mountains of different kinds of marble from quarries, both at home and abroad, together with great quantities of lime, iron, brass, and other materials for building, he fixed a day for the great ceremony of laying the foundation, which he contrived to make a very effectual mean of raising the superstructure; for on the long-expected day, the feast of the holy virgins Felicitas and Perpetua, an immense multitude of earls, barons, and knights, with their ladies and families, of abbots, priors, monks, nuns, clerks, and persons of all ranks, arrived at Croyland to assist at this ceremony. The pious abbot Joffred began by saying certain prayers, and shedding a flood of tears on the foundation. Then each of the earls, barons, knights, with their ladies, sons, and daughters, the abbots, clerks, and others, laid a stone, and upon it deposited a sum of money, a grant of lands, tithes, or patronages, or a promise of stone, lime, wood, labour, or carriages for building the church. After this the abbot entertained the whole company, amounting to five thousand persons, to dinner. To this entertainment they were well entitled; for the money and grants of different kinds which they had deposited on the foundation stones were alone sufficient to have raised a very noble fabric." This spirit extended throughout the island; for, in Scotland, David I. raised thirteen abbeys and priories, some of them on a scale of considerable magnificence, besides several cathedrals and other churches.

393. The common people of the country, and the burgesses in the towns, were not much better lodged than in the previous age; their condition, indeed, was not improved. In London, towards the end of the twelfth century, the houses were still built of timber, and covered with reeds or straw. The palaces, however, or rather castles, of the Anglo-Norman kings, nobility, and prelates, were on a very superior construction. William of Malmesbury says that the Anglo-Saxon nobility squandered their ample means in low and mean dwellings; but that the French and Norman barons lived at less expense, though dwelling in large and magnificent palaces. The fact is, that among these latter the rage for erecting fortified castles was quite as great as that of erecting ecclesiastical buildings among the prelates. The system became necessary, and was induced as well by the previous habits of the country they had left, as by their situation in the island. Surrounded by vassals whom they held in subjection, and whom they depressed and plundered in every way, they were so detested by them that deep fosses and lofty walls were necessary for their security. The Conqueror himself, aware that the want of fortified places had no less assisted his conquest than it might his expulsion, resolved to guard against such a contingency by the strong castles which he placed within the royal demesnes. Matthew Paris observes that William excelled all his predecessors in the erection of castles, in executing which he harassed his subjects and vassals. So much was the practice a matter of course, that the moment one of the nobility had the grant of an estate from the crown, a castle was built upon it for his defence and residence; and this spirit was not likely to be diminished by the disputes relative to the succession in the following reigns. William Rufus, according to the statement of Henry Knighton, was as much addicted to the erection of royal castles and palaces as his father, as the castles of Dover, Windsor, Norwich, and others sufficiently prove; and it is certain that no monarch before him erected so many and noble edifices. Henry I. followed in his taste; but in the reign of Stephen, 1135 to 1154, says the author of the *Saxon Chronicle*, every one who had the ability built a castle, and the whole kingdom was covered with them, no fewer than 1115 having been raised from their foundations in the short space of nineteen years; so that the expression is by no means stronger than is justified by the fact.

394. It will be proper here to give the reader some concise general description of these structures, which served for residence and defence. The situation chosen for a castle was usually on an eminence near a river. Its figure on the plan was often of great extent, and irregular in figure; and it was surrounded by a deep and broad ditch, called the *fosse*, which could be filled with water. An outwork, called a *barbican*, which was a strong and lofty wall, with turrets upon it, and designed for the defence of the great gate and draw-bridge, was placed before the latter. Within the ditch, towards the main building, was placed its wall, about 8 or 10 ft. thick, and from 20 to 30 ft. high, with a parapet and embrasures, called *crenells*, on the top. At proper intervals above the wall square towers were raised, two or three stories in height, wherein were lodged some of the principal officers of the proprietor of the castle, besides their service for other purposes; and, on the inside, were apartments for the common servants or retainers, granaries, storehouses, and other necessary offices. On the top of the wall, and on the flat roofs of the towers, the defenders were placed in the event of a siege; and thence they discharged arrows, darts,

and stones on their assailants. The great gate was placed in some part of the wall flanked with a tower on each side, with rooms over the entrance, which was closed with massive oak folding doors, frequently plated with iron, and an iron grate, or *portcullis*, which, by machinery, was lowered from above. Within this exterior wall, or ballium, was, in the more extensive castles, the outer ballium, which was a large open space or court, wherein a church or chapel was usually placed. Within the outer ballium was another ditch, with wall, gate, and towers, inclosing the inner ballium or court, in which was erected the large tower, or *keep*. It was a large fabric, some four or five stories high, whose enormously thick walls were pierced with very small apertures, serving barely as windows to the gloomy apartments upon which they opened. This great tower was the dwelling of the owner of the castle; and in it was also lodged the constable, or governor. It was provided with underground dismal apartments for the confinement of prisoners, whence the whole building received the appellation of *dungeon*. In the keep was also the great hall, in which the friends and retainers of the owner were entertained. At one end of the great halls of castles, palaces, and monasteries, a low platform was raised a little above the rest of the floor, called the *dais*, on which stood the principal table whereat persons of higher rank were placed. The varieties which occurred in the arrangement and distribution of castles were, of course, many, as circumstances varied; but the most magnificent were erected nearly on the plan we have just described, as may be gathered as well from their ruins as from an account by Matthew Paris of the taking of Bedford Castle by Henry III., A.D. 1224. This castle, we learn from him, was taken by four assaults. In the first was taken the bar-bican; in the second, the outer ballium; in the third attack, the miners threw down the wall by the old tower, where, through a chink, at great risk, they possessed themselves of the inner ballium; on the fourth assault, the miners fired the tower, which thereby became so injured and split that the enemy thereon surrendered. The keeps of which we have spoken are such extraordinary edifices, that we think it right to place before the reader, from the *Discourses upon Architecture* of our late much esteemed and learned friend, the Rev. James Dallaway, the following table of some of the principal ones of the Norman era.

Internal Square, or Oblong.					
Names.	Length.	Breadth.	Height.	Division of Rooms.	Dates and Founders.
Tower of London -	116 ft.	96 ft.	— ft.	By semicircular arches.	William the Conqueror.
Porchester -	115	65	—	Four floors.	
Canterbury -	88	80	50	Two walls continued from the base to the top.	
Rochester -	75	72	104	By semicircular arches.	Gundulph (Bishop).
Dover -	—	—	92	- - - -	
Colchester -	140	102	—	Three large rooms on each floor.	
Norwich -	110	92	70	- - - -	Roger Bigod. Roger de Laci.
Ludlow -	—	—	110	Four stories.	
Hedingham -	62	55	100	Three tiers above base-ment.	
Guildford -	42	47	—	- - - -	Robert D'Oiley. 1070. 1100.
Oxford -	-	-	-	- - - -	
Bamborough -	-	-	-	- - - -	
Richmond -	-	-	-	Vault supported by a single octangular pillar.	
Newcastle upon Tyne	82	62	54	By internal arches and door cases in Norman style.	1080. Robert Curthose.
Corfe -	72	60	80	- - - -	- - - -
Round, or Polygonal.					
Arundel -	69	57	—	Roof open in the centre, straight buttresses.	1070. Roger Montgo-meri.
Conisburgh -	23 diameter.		-	Three floors, two of them state apart-ments.	1070. W. de Warren.
York -	64	45	-	Four segments of circles	1068. William the Con-queror.
Tunbridge	64	50	—	Circular, flanked by four small towers.	1120. Rob. Fitzharding.
Berkeley -	-	-	-		
Lincoln -	-	-	—	- - - -	1086. William the Con-queror.
Oxford -	-	-	-	Polygon, flanked by three square towers.	
Windsor -	90	85	—	- - - -	Rebuilt by Edw. III. Heightened in 1830.
Durham -	63	61	—	- - - -	

395. Gundulph is said to have introduced the architectural ornaments of the Norman style into the interior as well as on the exterior of castles. The use of battlements, loop-

holes, and open galleries, or machicolations, was certainly, as our author above quoted remarks, known to the Romans.

—Troes contra, defendere saxis  
Perque cavas densi tela intorquere fenestras.

Æn. l. ix. 533.

The architects and artificers by whom the Norman works were planned and executed were men of great science and skill, and the names of several have most deservedly obtained a place in history. Gervase of Canterbury records that William of Sens, the architect of Archbishop Lanfranc in building his cathedral, was an artist of great talents; and that he not only made a complete model of the cathedral upon which he was employed, but of all the details of sculpture necessary for its execution, besides inventing machines for loading and unloading the vessels, and conveying the heavy materials, many whereof were brought from Normandy. Of Walter of Coventry, another architect of the age, Matthew Paris speaks in the highest terms, saying that "so excellent an architect had never yet appeared, and probably never would appear in the world." Dr. Henry on this very properly observes, "That this encomium was undoubtedly too high; but it is impossible to view the remains of many magnificent fabrics, both sacred and civil, that were erected in this period, without admiring the genius of the architects by whom they were planned, and the dexterity of the workmen by whom they were executed."

396. Of the twenty-two English cathedrals, fifteen retain parts of Norman erection, whose dates are pretty well ascertained; and by them the Norman manner was progressively brought to perfection in England. We subjoin the following enumeration of Norman bishops, who were either patrons of the art, or practising it themselves.

A. D.	Bishop, or Architect.	Works.
1059 to 1089	Aldred, Bishop of Worcester.	St. Peter's, Gloucester:
1077 to 1107	Gundulph, of Rochester.	Rochester, Canterbury, and Peterborough.
1086 to 1108	Maurice, of London.	Old St. Paul's Cathedral.
1093 to 1133	William de Carlepho.	Cathedral of Durham, but completed by Ranulph Flambard.
1080 to 1100	Lanfranc, of Canterbury.	Cathedral at Old Sarum.
1107 to 1140	Roger, of Salisbury.	Completed Gundulph's works at Rochester.
1115 to 1125	Ernulf, of Salisbury.	Rebuilt his cathedral.
1123 to 1147	Alexander, of Lincoln.	Conventual churches of St. Cross and Rumsey, in Hampshire.
1129 to 1169	Henry of Blois, Bishop of Winchester.	
1158 to 1181	Roger, Archbishop of York.	

Of Norman architecture the principal characteristics are subjoined in the following subsection.

397. *Arches*.—Generally semicircular, as in the nave of Gloucester, here given (*fig. 185*).

FIG. 185. ARCH FROM NAVE OF GLOUCESTER.

Of larger opening than the Saxon, and their ornaments less minute; often bounded by a single moulding, though sometimes by more than one; occasionally without any moulding at all; the soffitt always plain. In the second story, two smaller equal arches under one larger, with a column of moderate size, or even comparatively slender, between them. In the third story (see *fig. 186*), generally three together, the centre one higher and broader than the others, and opened for a window; but the whole three only occupy a space equal to that

FIG. 186. THREE STORIES OF A NORMAN CATHEDRAL.

of the lower arch. *Arches of entrance* are profusely decorated (*fig. 187*, from Ely) with mouldings, foliage, wreaths, masks, figures of men and animals in relief, and all the fancies of the wildest imagination, in which every thing that is extravagant, grotesque, ludicrous, nay, even grossly indecent, is to be found. Before the end of the period — and we may almost say early in it — it exhibits examples of *pointed arches*. They are, however, sparingly introduced: one or more tiers appear in the upper stories of a building, whilst all the lower ones are circular.

Sometimes they are intro-

duced alternately, sometimes we find one capriciously inserted between several round ones; these are, for the most part, obtusely pointed, though occasionally they are the reverse.

Fig. 187.

PRIOR'S ENTRANCE AT ELY.

They are always wide, stand on heavy columns, or are decorated with mouldings, or both. The approaches to the pointed style were not strongly marked, but they were indicated; for the pointed style cannot be pronounced to have commenced until the sharp-pointed arch sprung from a slender column graced with a capital of carved foliage, and this it is not safe to place earlier than the reign of John. The arch which rises more than a semicircle does not very often occur; but it must be mentioned as exhibiting one of the varieties of the period. *Columns.*—These are of very large diameter relative to their heights and intervals. Their shafts are circular, hexagonal, and sometimes octagonal, on the plan; fluted, lozenge, reticulated, and otherwise sculptured. Sometimes they are square on the plan, and then accompanied by portions of columns or pilasters applied to them. Sometimes four columns are connected together, with or without angular pieces. They are much higher in proportion to their diameters than the Saxon columns heretofore described; and though their capitals are not unfrequently quite plain, they are more commonly decorated with a species of volute,

or with plants, flowers, leaves, shells, animals, &c. The bases stand on a strong plinth, adapted on its plan to receive the combined and varied forms of the columns. *Windows,* are still narrow, and semicircular-headed; but they are higher, and often in groups of two or three together. *Ceilings,* usually, if not always, of timber, except in crypts, in which they are vaulted with stone, with groins mostly plain, yet sometimes ornamented on the edge, but universally without tracery. The White Tower of London, however, exhibits an example of a centre aisle covered with vaulting. Our belief is, and in it we are corroborated by the Rev. Mr. Dallaway, whose judgment we hold in no small esteem, that there is no instance of a genuine Anglo-Norman building which was intended to be covered with a stone roof or ceiling. This is not only indicated by the detail, but by the circumstance of the walls being insufficient (thick as they are) in solidity to resist the thrust. Peterborough, Ely, St. Peter's, Northampton, Steyning, Romsey, &c. are calculated and constructed to receive wooden roofs only. *Walls,* are of extraordinary thickness, with but few buttresses, and those of small projection; flat, broad, and usually without ornament. *Ornaments.*—Among these must be first named the ranges of arches and pilasters which had nothing to support, already incidentally mentioned, and which were intended to fill up void spaces, internally as well as externally, for the purpose of breaking up large masses of surface; they are very common on the inside of north and south walls, sometimes intersecting each other so as to produce those compartments that are alleged to have given rise to the pointed arch. The mouldings of the Saxon period continued much in use, and we ought, perhaps, to have given some of them, as belonging to the preceding section; and, indeed, should have so done, if, in the Norman style, they had not increased in number and variety, and had not also been employed in profusion about the ornamental arches just named, especially in conspicuous places on the outside, as in the west front especially. The most usual ornaments (*fig. 188.*) were, 1. The *chevron*, or *zigzag* moulding; 2. The *embattled frette*;

Fig. 188.

NORMAN ORNAMENTS.

3. The *triangular frette*; 4. The *nail-head*; 5. The *billet*; 6. The *cable*; 7. The *hatched*; 8. The *lozenge*; 9. The *wavy*; 10. The *pellet* moulding; 11. The *nebulæ*. The *torus* was used, as was also the *cavetto*, which were both of Grecian extraction. The chief of these ornaments, perhaps all, were used in the Saxon age, besides others which were occasionally employed, and which to designate by name would be difficult; such, for instance, as the *corbel-table* (12), which consists of small ranges of arches, resting on brackets sometimes decorated with carved heads, often introduced along the whole building immediately below the eaves or battlement. Sometimes carved heads are observed in the spandrels of arches, and are also used as capitals of the ornamented pilasters, or as corbels, to support what is called the canopy, or exterior semicircle of moulding on arches of entrance, or above the keystones of those arches. There are instances of whole figures over doors in mezzo-relievo, which Millers observes was the nearest approach the Normans seem to have made to a statue. *Plans*.—The churches of this period are always with transepts, and a tower at the intersection, loftier than heretofore, but without spires over them. There are rising from them stories of arches, one above the other; and the eastern ends are semicircular. Though much of the Saxon style is retained, there is, from the larger dimensions of the edifices of this period, a much more impressive air of magnificence than had before appeared. Millers very truly says, that the churches were “in all dimensions much simpler, with a general air of cumbrous massive grandeur. The Normans were fond of stateliness and magnificence; and though they retained the other characteristics of the Saxon style, by this amplification of dimensions they made such a striking change as might justly be entitled to the denomination which it received at its first introduction among our Saxon ancestors, of a *new style of architecture*.” The criterion between the Saxon and Norman styles, of enlarged dimensions, is too vague to guide the reader in a determination of the age of buildings of this period; for it is only in large edifices, such as cathedral and conventual churches, with their transepts, naves, side aisles, and arches in tier above tier, that this can be perceptible. There are many parish churches of this age, whose simplicity of form and small dimensions have been mistaken for Saxon buildings; and which, from not possessing any of the grander Norman features, have been assigned to an earlier age. The distinction ascertainable from heights of columns,—namely, taking the height of the Norman column at from four to six diameters, and that of the Saxon at only two,—will, we fear, be insufficient to decide the question in cases of doubt; but it must be admitted this is one of the means which, in some measure, would lead us to an approximate judgment of the matter, and a careful observation and comparison of specimens would make it more definite. We shall here merely add, that the first Norman architects, by the lengthened vista of the nave, uninterrupted by any choir screen, produced a sublime and imposing effect by the simple grandeur and amplitude of dimensions in their churches.

398. *Examples*.—Examples of Norman architecture in English cathedral churches are to be found at *Ely*, in the western towers and nave; at *Bristol*, in the elder Lady Chapel, and Chapter House; at *Canterbury* in the choir, and the round part called Becket's Crown; at *Norwich*,

in the nave and choir; at *Hereford*, in the transept tower and choir; at *Wells*, in the nave and choir; at *Chester*, in the Chapter House; at *Chichester*, in the presbytery; at *Peterborough*, in the transept. In the *conventual churches*, for examples we may refer the reader to *Llantony*, near Monmouth; the nave and west front of *Fountains*, Yorkshire; the nave and chapel of *St. Joseph*, at Glastonbury; the west front at *Selby*, in Yorkshire; many parts at *St. Alban's*; the choir at *Wenlock*, in Shropshire; *Cartmell*, in Lancashire; *Furness*; West End, at *Byland*, with the wheel window, and the south transept; parts of *Bolton*, in Yorkshire; part of *Brinkbourn*, in Northumberland; part of *Edmondsbury*, in Suffolk; and *St. John's Church*, at Chester. For examples of parochial churches, *Melton*, Suffolk; *Sotterton* and *Sleaford*, Lincolnshire; *Christchurch*, Hampshire; *Sherbourn Minster*, Dorset; *Winchelsea*, *Steyning*, and *New Shoreham*, Sussex; chancel of *St. Peter's*, Oxford; *Earl's Barton Tower*, Northamptonshire; *West Walton Tower*, Norfolk; *Iffley*, Oxfordshire; *Castle Rising*, Norfolk; *St. Margaret's Porch*, at York; *St. Peter's Church*, Northampton; besides several round or polygonal bell-towers, both in Suffolk and Norfolk, — may be referred to. Examples of *military Norman architecture*, from 1070 to 1270, were at *Launceston*, Cornwall; *Arundel*, Sussex; *Windsor*, in Berks (rebuilt); *Tower of London*; the square keeps of *Hedingham*, Essex; *Caerphilly*, Glamorgan; *Carisbrook*, Isle of Wight; *Porchester*, Hants (1160); *Guildford*, Surrey; *Bamborough*, Northumberland; *Kenilworth*, Warwickshire; *Richmond*, Yorkshire; *Cardiff*, Glamorganshire; *Canterbury*, Kent; *Oxford* (1071); *Newcastle*, Northumberland (1120); *Gisborough*, Yorkshire (1120); *Castle Rising*, Norfolk; *Middleham*, Yorkshire; *Cockermouth*, Cumberland; *Durham* (1153); *Lincoln* (1086); *Berkeley*, Gloucestershire (1153); *Lancaster*; *Orford*, Suffolk, polygonal (1120); *Ludlow*, Salop (1120); *Kenilworth*, enlarged (1220); *Warkworth*, Northumberland, square, with the angles cut off; *Denbigh*; *Beeston*, Cheshire; *Hawarden*, Pembrokeshire.

---

### SECT. III.

#### EARLY ENGLISH ARCHITECTURE.

399. The next period of architecture in Britain which comes under our consideration, following, as we consider it, the sensible classification of the Rev. Mr. Millers, is that which he has denominated the *early English style*, whose duration was from about 1200 to 1300; extending, therefore, through the reigns of John, Henry III., and Edward I., during which the building of churches and monasteries was still considered one of the most effectual means of obtaining the pardon of sin, and consequently the favour of Heaven. In the thirteenth and fourteenth centuries, the churches built in Britain were almost innumerable.

400. We have already noticed (chap. ii. sect. xv.) the introduction of the pointed arch into architecture; a feature which completely changed, from all that previously existed, the character of the edifices to which it was applied. If any service could be rendered to the history of the art, or if the solution of the problem, "who were its inventors?" could throw any useful light on the manners and customs of the people that first adopted it, we should be the last to relinquish the investigation. The question has furnished employment to many literary idlers, especially at the universities, whose time might, perhaps, have been more usefully employed in looking after the young men under their charge, especially as they have all, except Whittington, done little, if any thing, towards advancing a knowledge of the subject, which involves information possessed by few of them, of whom the latest have done the least.

401. During the reign of Henry III. alone, no less a number than 157 abbeys, priories, and other religious houses were founded in England. Several of our cathedrals and conventual churches in a great part belong to this period, in which the lancet or sharp-pointed arch first appeared in the buildings of this country, though on the Continent it was used nearly a century earlier. The great wealth of the clergy, added to the zeal of the laity, furnished ample funds for the erection of the magnificent structures projected; but it was with extreme difficulty that workmen could be procured to execute them. With the popes it was, of course, an object that churches should be erected and convents endowed; hence they granted by their bulls many indulgences to the Society of Freemasons, which had greatly increased in its numbers. These Freemasons appear to have ranged from one nation to another (*Wren's Parentalia*), as they found churches to be built: their government was regular, and when they fixed near the building in hand they made a camp of huts. A surveyor governed in chief; every tenth man was called a warden, and overlooked each nine. "Those who have seen the account in records of the charge of the fabrics of some of our cathedrals, near 400 years old, cannot but have a great esteem for their economy, and admire how soon they erected such lofty structures." It was in the

course of this period that sculpture was first made extensively available for architectural decoration. The cathedral, conventual, and other churches built in Britain, began to be ornamented on the outside with statues of various dimensions in basso and alto rilievo. They were not equal in execution to those of France, which have also had the additional good fortune to have been better preserved, from their exposure to seasons less inclement, and to an atmosphere unimpregnated with the smoke of coal.

402. Great improvements seem to have taken place in the castles of the time; they still continued to serve for the dwelling and defence of the prelates and barons of the country. The plans of them were generally similar to those already described; but it must still be conceded that the inhabitants and owners of them sacrificed their convenience to their security, which seems to have been the chief concern in the construction of their castles, whose apartments were gloomy, whose bed-chambers were few and small, whose passages were narrow and intricate, and their stairs steep and dark. The plan, however, as Mr. Dallaway observes, "which allowed of enlarged dimensions, and greater regularity and

beauty in the architecture of the towers, owes its introduction into England to King Edward I. We may, indeed, consider his reign as the epoch of the grand style of accommodation and magnificence combined in castle architecture. When engaged in the Crusades, he surveyed with satisfaction the superior form and strength of the castles in the Levant and in the Holy Land." Of the five castles erected

Fig. 189.

CAERNARVON CASTLE.

by him in Wales, Caernarvon (*fig. 189.*), Conway (*fig. 190.*), Harlech, and Beaumaris still retain traces of their ancient magnificence; but that of Aberystwith has scarcely a feature left.

Fig. 190.

CONWAY CASTLE.

Caernarvon Castle consisted of two distinct parts: one military, and suited to the reception of a garrison; the other palatial. The ground plan was oblong, unequally divided into a lower and an upper ward. Of the towers, which are all polygonal, the largest, from some tradition called the Eagle Tower, has three small angular turrets rising from it; the others having but one of the same description. "The enclosing walls," continues Mr. Dallaway, "are seven feet thick, with *alures* and parapets pierced frequently with *ailet* holes. A great singularity is observable in the extreme height both of the great entrance gate and that which is called the Queen's. Leland observes of the portcullises at Pembroke, that they were composed *ex solido ferro*. In confirmation of the opinion that the royal founder adopted the form of such gates of entrance from the East, similar ones are almost universal in the castles, mosques, and palaces of the Saracens, which he had so frequently seen during the Crusades. The tower of entrance from the town of Caernarvon is still perfect, and is the most handsome structure of that age in the kingdom. It is at least 100 ft. high; and the gateway, of very remarkable depth, is formed by a succession of ribbed arches, sharply pointed. The grooves for three portcullises may be discovered; and above them are circular perforations, through which missile weapons and molten lead might be discharged upon the assailants. In the lower or palatial division of the castle stand a large polygonal tower of four stories, which was appropriated to Queen Eleanor, and in which her ill-fated son was born, and another which was occupied by the king, of a circular shape externally, but square towards the court. The apartments in the last mentioned are larger, and lighted by windows with square heads, and intersected with carved mullions. There is a singular contrivance in the battlements, each of which had an excavation for the archers to stand in, pointing their arrows through the slits; and, a curious stratagem, the carved figures of soldiers with helmets, apparently looking over the parapet. This device is repeated at Chepstow." The ornamental character of the architecture at Caernarvon and Conway is rather ecclesiastical, or conventual, than military. At Conway, as has been well observed by an anonymous author, "what is

called the Queen's Oriel is remarkable for the fancy, luxuriance, and elegance of the workmanship. Nor is the contrivance of the little terraced garden below, considering the history of the times, a matter of small curiosity, where, though all the surrounding country were hostile, fresh air might be safely enjoyed; and the commanding view of the singularly beautiful landscape around, from both that little herbarry or garden, and the bay window or oriel, is so managed as to leave no doubt of its purpose."

FIG. 191.

CAER-PHILLY CASTLE.

403. The model of Conway Castle has little resemblance to that we have just left. It resembles rather the fortresses of the last Greek emperors, or of the chieftains of the north of Italy. The towers are mostly circular, as are their turrets, with a

single slender one rising from each; and machicolations, not seen at Caernarvon, are introduced. The greater part of the castles of Wales and Scotland for the defence of the

FIG. 192. TREFOIL AND CINQUEFOIL HEADS.

marches were built in the reign of Edward I. On the subjugation of the former country, and its partition into lordships among Edward's followers, many castles were reared upon the general plan of those he had erected, though varying in dimensions and situation, according to the means of defence proposed to be secured to their founders and possessors. We may here observe, that in the castle at Conway Edward I. erected a hall 129 ft. by 31, and 22 ft. high, which is formed to suit the curvature of the rock; and that from that period no residence of consequence, either for the nobility or feudal lords, was erected without one, varying, however, of course, in their minuter parts, according to circumstances, and in degree of magnificence.

FIG. 194. PLAN OF COLUMN.

404. Caer-Philly Castle, in Glamorganshire (*fig. 191.*), was another of the castles of this period. It was the strong-hold of the De Spencers in the reign of the second Edward. Its vallations and remains are very extensive. The hall was much larger than that at Conway.

405. The characteristics of this style are, that the *arches* are sharply (*lancet*) pointed, and lofty in proportion to their span. In the upper tiers two or more are comprehended under one, finished in *trefoil* or *cinquefoil* heads (*fig. 192.*) instead of points, the separating columns being very slender. *Columns* on which the arches rest (*fig. 193.*) are very slender in proportion to their height, and usually consist of a central shaft surrounded by several smaller ones (*fig. 194.*). The base takes the general form of the cluster, and the capital (*fig. 195.*) is frequently decorated with foliage very elegantly composed. The *windows* are long, narrow, and lancet shaped, whence some writers have called this style the *Lancet Gothic*. They are divided by one plain mullion,

FIG. 193. COLUMNS OF WESTMINSTER ABBEY.

FIG. 195. CAPITAL OF COLUMN.

or in upper tiers by two at most, finished at the top with some simple ornament, as a lozenge or a trefoil. They have commonly small marble shafts on each side, both internally and externally; two, three, or more together at the east or west end, and tier above tier. *Roofs* are high pitched and the ceilings vaulted, exhibiting the first examples of arches with cross springers only, which in a short period diverged into many more, rising from the capitals of the columns, and almost overspreading the whole surface of the vaulting. The longitudinal horizontal line which reigned along the apex of the vault was decorated with bosses of flowers, figures, and other fancies. *Walls* much reduced in thickness from those of the preceding period: they are, however, externally strengthened with buttresses, which, as it were, lean against them for the purpose of counteracting the thrust exerted by the stone vaults which form the ceilings, and which the walls and piers by their own gravity could not resist. The buttresses are moreover aided in their office by the pinnacles, adorned with crockets at their angles, and crowned with finial flowers, by which they are surmounted. *The ornaments* now become numerous, but they are simple and elegant. The mouldings are not so much varied as in the Norman style, and are generally, perhaps universally, formed of some combination of leaves and flowers, used not only in the circumference of arches, especially of windows, but the columns or pilasters are completely laid down with them. Trefoils, quatrefoils, cinquefoils, roses, mullets, bosses, pateræ, &c. in the spandril, or above the keystones of the arches and elsewhere. The ornamental pinnacles on shrines, tombs, &c. are extremely high and acute, sometimes with and sometimes without niches under them. In east and west fronts the niches are filled with statues of the size of life and larger, and are crowned with trefoil, &c. heads, or extremely acute pediments, formed by the meeting of two straight lines instead of arcs. All these ornaments are more sparingly introduced into large entire edifices than in smaller buildings or added parts. *The plans* are generally similar to those of the second period; but that important feature the tower now begins to rise to a great height, and lanterns and lofty spires are frequent accompaniments to the structure. It will naturally occur to the reader, that in the transition from the second to the third style, the architects left one extreme for another, though it has been contended that the latter has its germ in the former. However that may be, the period of which we are now speaking was undoubtedly the parent of the succeeding styles, and that by no very forced or unnatural relationship.

406. The principal examples of the early English style in the cathedral churches of England are to be seen at *Oxford*, in the chapter-house. *Lincoln*, in the nave and arches beyond the transept. *York*, in the north and south transept. At *Durham*, in the additional transept. *Wells*, the tower and the whole western front. *Carlisle*, the choir. *Ely*, the presbytery. *Worcester*, the transept and choir. *Salisbury*, the whole cathedral; the only unmixed example. At *Rochester*, the choir and transept. "It is well worthy of observation," says Mr. Dallaway, "that though the ground plans of sacred edifices are, generally speaking, similar and systematic, yet in no single instance which occurs to my memory do we find an exact and unvaried copy of any building which preceded it in any part of the structure. A striking analogy or resemblance may occur, but that rarely."

407. The examples of conventual architecture of this period, to which we beg to refer the reader, are those of *Lanercost*, in Cumberland; *Rivaux*, Yorkshire; *Westminster Abbey*. At *Fountains*, the choir and east end; *Tintern Abbey*, in Monmouthshire; *Netley*, Hampshire; *Whitby*, in Yorkshire; *Valle Crucis*, in Denbighshire; *Ripon Minster* and the south transept of *Beverley Minster*, in Yorkshire; *Milton Abbey*, Dorsetshire; *part of the nave of St. Alban's*; *Tinemouth* and *Brinkbourn*, Northumberland; *Vale Royal*, in Cheshire; and the eastern façade of *Houdden*, in Yorkshire.

408. Among the examples of parochial churches in this style are *Grantham*, in Lincolnshire, whose tower is 180 ft. high; *Attelborough*, in Norfolk; *Higham Ferrars*, in Northamptonshire; *St. Michael, Coventry*; *Truro*, in Cornwall; *Witney*, in Oxfordshire; *Stratford upon Avon*, in Warwickshire; *St. Peter Mancroft*, Norwich; *Boston*, Lincolnshire, remarkable for its lantern tower rising 262 ft. from the ground, and perhaps almost belonging to the succeeding period; *St. Mary, Edmund's Bury*, Suffolk; *Maidstone*, in Kent; and *Ludlow*, in Shropshire.

## SECT. IV.

### ORNAMENTED ENGLISH ARCHITECTURE.

409. The fourth period in the architecture of Britain is that which Mr. Millers calls the *Ornamented English Style*, which begins about 1300 and lasts till 1460, and comprises, therefore, the latter portion of the reign of Edward I., and the reigns of Edward II., Edward III., Richard II., Henry IV., Henry V., and Henry VI.

410. This æra has by Dallaway and others been subdivided into two parts, viz. first

from 1300 to 1400, which they call that of the Transition Style or pure Gothic, and from 1400 to 1460, called the Decorated Gothic; but the change between the latest examples of the first and the earliest of the last is marked by such nice and almost imperceptible distinctions, that it is next to impossible to mark their boundaries with precision; and we have therefore preferred adhering, as we have in the other ages of the art, to the arrangement adopted by Mr. Millers. In the early part of the period the change, or rather progress, was extremely slow, and marked by little variation, and, indeed, until 1400, the style can scarcely be said to have been perfected; but after that time, it rapidly attained all the improvement whereof it was susceptible, and so proceeded till about 1460; after which, as we shall hereafter see, it assumed an exuberance of ornament, beyond which as it was impossible to advance, it was in a predicament from which no change could be effected but by its total abandonment.

411. Notwithstanding the wars of the rival houses of York and Lancaster, which occupied a considerable portion of the interval whereof we are speaking, and deluged, as the reader will recollect, our land with the blood of the bravest of men, the art did not appear to suffer; a circumstance apparently extraordinary, but satisfactorily accounted for by the zeal of both the contending parties for the religion they in common professed. True it is that the taste for founding and building monasteries and churches was not so universal as in the period last described; the decline, however, of that taste might in some measure have arisen not only from the unhappy state of the country just alluded to, but also from the doubts raised in the minds of many persons of all ranks by Wickliffe and his followers as to the merit attached to those pious and expensive works. "It cannot," says Henry, "be denied that the style of sacred architecture commonly called Gothic continued to be greatly improved, and in the course of this period was brought to the highest perfection." To account in some measure for this, it must be recollected that during the civil wars the superior ecclesiastics were confined to their cloisters, as few of them had taken an active part in the dispute which agitated the realm; and, indeed, some of the finest structures now remaining were reared from the accumulation of wealth amassed by instigating the noble and affluent to contribute to churches built under their own inspection. The choir at Gloucester, a most beautiful example, was completed during these turbulent times by Abbot Sebroke, together with the arcade that supports the magnificent tower of that cathedral.

412. During this period the efforts of painting and sculpture were superadded to those of architecture; and to these must be joined the enchanting effects produced by expanded windows glowing with the richest colours that stained glass could bestow on them. To enter into a history of the rise, progress, and perfection of this art, would here be out of place. A separate work would be required to trace it from its introduction in this country as connected with our art in the reign of Henry III., to that point when it reached its zenith in the fifteenth century. Dallaway observes, with much truth, that it is a vulgar error to suppose the art was ever lost, inasmuch as we had eminent professors of it in the reign of Charles I.

413. In military architecture, from the reign of Edward III. to the close of the contention between the houses of York and Lancaster, many improvements were effected. Within that period a great number of the castellated edifices of which the country could boast were erected or renewed. Their style is marked by turrets and hanging galleries over the salient angles and gateways, of great variety in design. In the fortress at Amberley, in Sussex, built by William Rede, Bishop of Chichester, about 1370, and one of the ablest geometricians of the age, the ground plan is nearly a parallelogram with four large towers at the angles, not projecting externally, but inserted into the side walls. Of this æra is also, at Swansea Castle, the lofty perforated parapet or arcade, through which the water was conveyed from the roof. Upon this plan Henry Gower, Bishop of St. David's, in 1335, improved, in his magnificent castellated palace at Llanphay Court.

414. From the circumstance of the circuit of many of the castles encompassing several acres of ground, the base court was proportionably spacious; hence the halls and other state apartments were lighted by windows, smaller, but similar in form to those used in churches. The rest of the apartments were unavoidably inconvenient, defence being the chief consideration. In the castles and palaces of the period, the *halls*, which formed a principal feature in them, require some notice. The earliest whereof mention is made was that built by William Rufus in his palace at Westminster. Hugh Lupus erected one at Chester, and one was executed for Robert Consul at Bristol. Others we find erected by Henry I. at Woodstock and Beaumont in Oxford; probably of rude construction, and divided into two aisles by piers of arcades or timber posts. In the following century, when castles began to be constantly inhabited, and space became requisite for holding the numerous feudal dependents on various occasions, the size of the hall was of course increased, and internal architecture and characteristic ornaments were applied to it. At the upper end, where the high table was placed, the floor was elevated, forming a *haut pas* or *dais*, a little above the general level of the floor. The example afforded by Edward III. at

Windsor was followed during his own and the succeeding reign. The halls of Westminster and Eltham were rebuilt by Richard II. ; Kenilworth by John of Gaunt ; Dartington, in Devonshire, by Holland Duke of Exeter. Crosby Hall, in London, was finished by the Duke of Gloucester, afterwards Richard III. We here subjoin the dimensions of some of the principal halls in castles and palaces before the end of the fifteenth century, ranged in order of their size : —

	Length in feet.	Breadth in feet.	Height in feet.
Westminster (1397)	228	66	92
Durham Castle	180	50	36
Conway (roof laid on stone ribs)	129	31	22
Bristol (divided by upright beams of timber)	108	50	—
Windsor (ancient)	108	35	—
Eltham (1386)	100	36	55
Chester	99	45	—
Kenilworth (1300)	90	50	—
Raby	90	36	—
Lumley	90	—	—
Swansea	88	30	—
Castle Hall, Leicester	78	51	24
Spofforth	76	36	—
Dartington (1476)	70	40	44
Caerphilly	70	—	35
Crosby Place	69	27	38
Goodrich	65	28	—
Warwick	62	35	25
Second one at Swansea	58	33	—
Berkeley	51	32	—

415. Generally, in respect of plan, the internal arrangement of these halls was very similar. The high table, as we have observed, was elevated on a platform above the level of the floor, and was reserved for the lord and his family, with the superior guests. Round the walls separate tables and benches were distributed for the officers of the household and dependents. The centre was occupied by the great open fire-place, directly over which in the roof was placed a turret, denominated a *louvre*, for conveying away the smoke. At Bolton Castle we find the chimneys in the walls ; but, perhaps, those at Conway and Kenilworth are earlier proof of the alteration. The roofs with which some of these halls are spanned exhibit mechanical and artistic skill of the first order. The thrust, by the simplest means, is thrown comparatively low down in the best examples, so as to lessen the horizontal effect against the walls, and thus dispense with considerable solidity in the buttresses. *Fig. 196.* is a section of the celebrated Hall of Westminster, by which our observation will be better understood. These roofs were framed of oak or chestnut. Whether, when of the latter, it was imported from Portugal and Castile, is a question that has been discussed, but not determined, by antiquaries. Large stone corbels and projecting consoles were attached to the side walls, and were disposed in bays called *severys* between each window. Upon their ends, demi-angels were generally carved, clasping a large escocchion to their breasts. Near to the high table, a projecting or bay window, termed an *oriel*, was introduced. It was fully glazed, frequently containing stained glass of the arms of the family and its alliances. Here was the standing cupboard which contained the plain and parcel-gilt plate. The *rere-dos* was a sort of framed canopy hung with tapestry, and fixed behind the sovereign or chieftain. The walls were generally lined to about a third of their height with panelled oak or strained suits of tapestry. It was during this æra that privy chambers, parlours, and bowers found their way into the castle. Adjoining to, or nearly connected with the hall, a spacious room, generally with a bay window, looking on to the quadrangle, was planned as a receiving-room for the guests, as well before dinner as after. This was decorated with the richest tapestry and cushions embroidered by the ladies, and was distinguished by the name of the *presence* or *privy-chamber*. The females of the family had another similar apartment, in which their time was passed in domestic occupations and amusements. This last room was called *my lady's bower* or *parlour*, and here she received her visitors. Bay windows were never used in outer walls, and seldom others, excepting those of the narrowest shape.

416. The dawn of improvement in our domestic architecture opened in the latter part of the period, during which also brick came very much into use in England as a building material. "Michael de la Pole," as we learn from Leland's *Itinerary*, "marchant of Hull, came into such high favour with King Richard II. that he got many privileges for the towne. And in hys tyme the towne was wonderfully augmented yn building, and was enclosyd with ditches. and the waul begun ; and in continuance endid, and made all of brike, as most part of the houses at that time was. In the waul be four principal gates of brike." After

Fig. 196.

SECTION OF WESTMINSTER HALL

enumerating twenty-five towers, "M. de la Pole," we find from Leland, "buildid a goodlie house of brike, against the west end of St. Marye's church, lyke a palace, with goodly orcharde and garden at large, also three houses besides, every on of which hath a tower of brik." (*Itin.* vol. i. p. 57.) This was the first instance of so large an application of brick in England.

417. One of the most important parts of the castle was the great gateway of entrance, in which were combined, at the same time, the chief elements of architectural beauty and military defence. It usually occupied the central part of the screen wall, which had the aspect whence the castle could be most conveniently approached. Two or more lofty towers flanked either side, the whole being deeply corbelled; a mode of building brought by the Arabs into Europe, and afterwards adopted by the Lombards and Normans. The corbel is a projecting stone, the back part whereof, which lies in the wall, being balanced by the superincumbent mass, it is capable of supporting a parapet projecting beyond the face of the wall rising from the horizontal course laid immediately on the corbels, between which the said horizontal course was pierced for the purpose of enabling the besieged to drop missiles or molten metal on the heads of the assailants. The corbel is often carved with the head of a giant or monster, which thus seems attached to the walls. In John of Gaunt's entrance gateway at Lancaster, the arch is defended by overhanging corbels with pierced apertures between them, and on either side are two light watch-towers crested with battlements.

418. Of the military architecture of this time, a perfect idea may be obtained from the two remarkable towers of Warwick Castle (*fig.* 197.), which were erected (in 1395) by Thomas de Beauchamp Earl of Warwick. The taller one rises 105 ft. above its base, and is 38 ft. diameter, having five stories, which are separated from each other by groined ceilings. In the interior, the walls of the state chambers were painted; a practice introduced into England in the beginning of the thirteenth century; and they were

FIG. 197.

WARWICK CASTLE.

examples that famed curiosity the triangularly formed bridge of Croyland in Lincolnshire, erected over the confluence of three streams. Bridge architecture was in many instances

FIG. 198. ARCH OF YORK MINSTER.

so necessarily connected with the construction of a fortress, that it may almost, in this age, be taken as a branch of military architecture.

420. This style exhibits *Arches*, less acute and more open (*fig. 198.* from York Minster), the forms varying. *Columns.* — The central and detached shafts now worked together into one, from experience of the weakness of those of the previous style, exceedingly various in their combinations. The *Windows* are larger, divided by mullions into several lights spreading and dividing at top into leaves, flowers, fans, wheels, and fanciful forms of endless variety. These marks are constant, but in the proportionate breadth there is much variation, for after having expanded in the reigns of Edward I. and II., they grew narrower again in proportion to their height in that of Edward III. and also sharper. The head was then formed of lines just perceptibly curved, sometimes even by two straight lines, sometimes just curved a little above the haunches, and then rectilinear to the apex. Eastern and western windows very lofty and ample, and splendidly decorated with painted glass. *Roof or Ceiling.* — The vaulting more decorated. The principal ribs spread from their imposts running over the vault like tracery, or rather with transoms divided into many angular compartments, and ornamented at the angles with heads, orbs, historical or legendary pictures, &c., elaborately coloured and gilded. *Ornaments.* — More various and laboured, but not so elegant and graceful in character, as

in the preceding style. Niches and tabernacles with statues in great abundance. Tiers of small ornamental arches are frequent. The pinnacles are neither so lofty nor tapering, but are more richly decorated with leaves, crockets, &c. Sculpture is introduced in much profusion, and is frequently painted and gilt. Screens, stalls, doors, pannelled ceilings, and other ornaments, in carved and painted wood.

421. The principal examples of the ornamented English style in cathedral churches, are at *Exeter*, the nave and choir. *Lichfield*, uniformly. At *Lincoln*, the additions to the central tower. At *Worcester*, the nave. *York*, nave, choir, and western front. At *Canterbury*, transept. At *Gloucester*, transept and cloisters begun. *Norwich*, the spire and tower. *Salisbury*, spire and additions. *Bristol*, the nave and choir. *Chichester*, the spire and choir. *Ely*, Our Lady's Chapel and the central louvre. *Hereford*, the chapter-house and cloisters, now destroyed. In the later part of the period, the choir at *Gloucester*; the nave at *Canterbury* Bishop Beckington's additions at *Wells*, and from the upper transept to the great east window at *Lincoln*. In conventual churches, for the earlier part of the period, the western façade of *Howden* (1320.), *Chapel of Merton College, Oxford*. *Gisborne Priory, Yorkshire*. *Chapel at New College, Oxford*. *St. Stephen's Chapel, Westminster*. The additions to the pediments of the choir at *Kirkstall, Yorkshire*. *St. Mary's in York*. *Kirkham* in Yorkshire, and the choir of *Selby*, in the same county. For the later part of

sometimes lined with wainscot of curious carved *boiserie* on the panels, which afterwards became more adorned, and were hung with tapestry. At Warwick was a memorable suit of arras whereon were represented the achievements of the famous Guy Earl of Warwick.

419. The period of which we are treating was as celebrated for its bridge as for its military architecture, and exhibits as one of its

the period, at *Tewkesbury*, the choir. At *Ely Cathedral*, *St. Mary's Chapel*, *Croyland* façade in Lincolnshire. *Beverley Minster* in Yorkshire. *Chapel of Magdalen College*, Oxford. *Eton College Chapel*, Bucks. *Chapel on the Bridge* at *Wakefield* in Yorkshire, built by Edward IV. in memory of his father Edward Duke of York; and the *Beauchamp Chapel* at *Warwick*. In parochial churches, for the early part of the period, examples may be referred to at *Grantham*, Lincolnshire. *Attelborough*, Norfolk. *Higham Ferrers*, Northamptonshire. *St. Michael*, Coventry. *Truro*, Cornwall. *Witney*, Oxfordshire. *Stratford-upon-Avon*, Warwickshire. *St. Peter Mancroft*, Norwich. *Boston*, Lincolnshire; its remarkable lantern tower, which is 262 ft. high, was begun in 1309, and was in progress of execution during the whole reign of Edward III. The expense of it having been chiefly defrayed by the merchants of the Hanse Towns. *St. Mary, Edmunds Bury*, Suffolk. *Maidstone*, Kent; and *Ludlow*, Salop. For the later part of the period, *St. Mary Overy*, Southwark. *Thaxted* and *Saffron Walden*, Essex. *Lowth* and *Stamford*, Lincolnshire. *Campden*, Gloucestershire. *St. Mary Redcliff* and the tower of *St. Stephen*, Bristol. *Taunton* and *Churton Mendip*, Somersetshire. *Lavenham*, Suffolk. *Manchester College*. *St. Mary's*, Oxford. *Whittlesea*, Cambridgeshire. *Wakefield*, Yorkshire. *Doncaster*, Yorkshire. *Newark-upon-Trent*. *Heckington*, Lincolnshire. *Mould Gresford* and *Wrezham* in Flintshire. *Melton Mowbray*, Leicestershire. *Octangular towers of St. Margaret's*, Norwich, and *All Saints*, York.

## SECT. V.

## FLORID ENGLISH OR TUDOR STYLE.

422. "There is," as Dr. Henry observes, "a certain perfection in art to which human genius may aspire with success, but beyond which, it is the apprehension of many, that improvement degenerates into false taste and fantastic refinement. The rude simplicity of Saxon architecture was (ultimately) supplanted by the magnificence of the ornamental Gothic; but magnificence itself is at last exhausted, and it terminated during the present period in a style, which some, with an allusion to literature, denominate 'the Florid.' It is a style censurable as too ornamental, departing from the grandeur peculiar to the Gothic, without acquiring proportional elegance; yet its intricate and redundant decorations are well calculated to rivet the eye, and amaze, perhaps bewilder, the mind." The period of the style is from 1460, to the dissolution of the religious houses in 1537, and comprehends, therefore, the reigns of Edward IV. and V., Richard III., Henrys VII. and VIII.

423. The ecclesiastical buildings of this æra are few. Somersetshire, a county devoted to the cause of the House of Lancaster, from the gratitude or policy of Henry VII., boasts perhaps more churches than any other county in the florid style; still they are very few, and the superb chapel which that monarch erected at Westminster is the best specimen that can be adduced for giving the reader a proper and correct idea of the Florid or Tudor style. There is doubtless an abundance of examples in oratories, porches, and small chapels, sepulchral sacella and the like; but beyond them we could cite very few entire sacred buildings; and those will be hereafter appended to this section as in the preceding ones. In civil, or rather domestic architecture, the case was far different: a very great change took place; and we shall endeavour to place a succinct account of it from the Rev. Mr. Dallaway's work, to which we have already been much indebted. The fifteenth century exhibits to us a number of vast mansions of the noble and opulent, wherein the characteristic style of the immediately preceding castles was not entirely abandoned, but superseded and mixed up with a new and peculiar one. The household books of the nobility which have come to our knowledge, indicate a multitudinous set of servants and retainers, for the reception of whom a great area of ground must have been covered, and in which provision, by the number of apartments, was made for a noble display of hospitality. This circumstance, of course, induced a gorgeous style peculiar to the earlier Tudor æra, of most of whose splendid mansions no memorial now exists but in the records of the times. But for the purpose of bringing a view of the whole subject under the eye of the reader, a brief recapitulation will here be necessary. The first palace of the Norman kings was the Tower of London, which was a strictly military residence. At Westminster was a palace of William Rufus, to whom Westminster Hall owes its original foundation. At Oxford a palace was built by Henry I., and at that place he kept his Christmas in 1115, as in 1229 and 1267 Henry III. did in the vicinity at Woodstock. It was at this place that Henry II. built a house of retirement, which has furnished the subject of some well-known legends. Henry III. is said to have refounded the palace at Westminster, which was much enlarged by Edward III. This, from the time of Rufus, its founder, to the reign of Richard II., to whom it owed its completion in the state apartments, with its magnificent hall and bijou of a chapel (St. Stephen's), had attained a greater extent than any contem-

porary palace in Europe. Edward III., besides erecting his suburban palace at Kennington, had re-edified and greatly extended Windsor Castle as a habitable fortification. Henry IV. inherited John of Gaunt's castle of Kenilworth and the Savoy in London, to both of which he made great additions. His gallant and victorious son was too much occupied with his military affairs to pay much attention to such matters; but many of his commanders, by the exorbitant ransoms they exacted of their French prisoners, were enabled to construct mansions of vast extent in those counties where their revenues commanded influence. Of these, as signal examples, may be cited Hampton Court in Herefordshire by Sir Rowland Lenthall; and Ampthill, Bedfordshire, by Sir John Cornwall Lord Fanhope. At Greenwich, a palace of great beauty, in the early part of the reign of Henry VI., was built by the regent Humphrey Duke of Gloucester, which, from its superiority over others, was by its founder called *Placentia* or *Plaisance*. This was completed by Edward IV., and is now remembered as the birthplace of Queen Elizabeth. The Lord Treasurer Cromwell expended a large sum on his residence at Tattershall in Lincolnshire, and at Wingfield Manor in Derbyshire, as did Lord Say and Sele, and Lord Boteler, respectively, at Sudley in Gloucestershire, and Hurstmonceaux in Sussex, all of which are now either destroyed or only in ruins. Additions were made by Edward IV. to Nottingham Castle, and by his brother Richard III. to Warwick Castle and that of Middleburg in Yorkshire.

424. Upon the establishment of the Tudor dynasty, Henry VII., on the ruins of a former palace at Shene in Surrey, which after the repairs he bestowed upon it was destroyed by fire, built a palace, whereto he gave the name of *Richmond*, in allusion to his former title, a name which was afterwards given to the beautiful town on the Thames, in its vicinity. The dimensions of the state apartments in this splendid building, whereof not a vestige now remains, are to be found in the Survey of 1649, when it was offered for sale by the Commissioners of Parliament. They abounded with bay windows of capricious formation, with rectangular and semicircular projections, producing a picturesque effect; and to add to its fantastic appearance, there were many octangular towers, surmounted with cupolas of the same plan, whose mitres as they rose were fringed with rich crockets. They were bulbous in their general form, thus bearing a resemblance in contour to the royal crown of the period.

425. The Tudor style, in domestic architecture, is thus divided by Mr. Dallaway. "1. That just alluded to; 2. The variations under Henry VIII.; 3. The Elizabethan style" (which will form a separate section), "as it admitted of Italian ornament in the designs of John of Padua and his followers, until the time of Inigo Jones.

426. The reign of Henry VIII. supplies numberless instances of the gorgeous expense to which the nobility and gentry proceeded in the productions of our art. The example set by the monarch himself was witnessed in no less than two royal mansions, each large enough to contain his numerous retinue. The following are the palaces that were built or repaired by Henry VIII. :—

1. Beaulieu, or Newhall, Essex.
2. Hunsdon, Herts, originally built by Sir John Oldhall, temp. Edw. IV
3. Ampthill, Bedfordshire.
4. Nonsuch, Surrey.
5. York Place, Whitehall, Westminster.
6. Bridewell and Blackfriars, London, for the reception of the emperor Charles V.
7. St. James's, Westminster.
8. Kimbolton, Huntingdonshire, the jointure of the divorced Queen Catharine of Arragon.
9. Sheriff Hutton, Yorkshire, given for the residence of Henry Duke of Richmond, the king's natural son.
10. King's Langley, Herts.

It was natural that the courtiers of such a monarch should vie with each other in erecting sumptuous houses in the provinces where they were seated. Wolsey, besides the progress he had made, at the time of his fall, in his colleges at Christchurch, Oxford, and Ipswich, had completed Hampton Court, and rebuilt the episcopal residences of York House (afterwards Whitehall), and Esher in Surrey. Edward Stafford, Duke of Buckingham, in his palace at Thornbury, Gloucestershire, almost rivalled the cardinal, and perhaps might have done so entirely if he had not been hurried to the scaffold before his mansion was completed. Grimsthorpe, in Lincolnshire, rose under the orders of the Duke of Suffolk (Charles Brandon). The Duke of Norfolk and his accomplished son, the Earl of Surrey, were, as appears from the descriptions of Kenninghall, Norfolk, and Mount Surrey, near Norwich, magnificent in the mansions they required for their occupation. We shall merely add the following list (which might, if it were necessary, be much augmented) of some other mansions of note. They are—1. Haddon Hall, Derbyshire. 2. Cowdray, Sussex, destroyed by fire in 1793. 3. Hewer Castle, Kent. 4. Gosfield Hall, Essex, perfect. 5. Hengrave Hall, Suffolk, perfect, and whereof a beautiful work has been published by John Gage, Esq. (now Rookwode), a descendant of its ancient possessors. 6. Layer Marney, Essex, now in ruins. 7. Raglan Castle, Monmouthshire, in ruins. 8. Hunsdon House, Herts, rebuilt. 9. South Wingfield, Derbyshire, dilapidated. 10. Hill Hall, Essex, built by Sir Thomas Smyth, in 1542. 11. Wolterton (see *fig.* 199.)

in East Barsham, Norfolk, in ruins. 12. Harlaxton, Lincolnshire, perfect. 13. Westwood, Worcestershire, perfect.

Fig. 199.

WOOLFELTON HOUSE.

427. In a very curious tract, entitled, "A Dyetorie or Regiment of Health," by Andrew Boorde, of Physike Doctor, 8vo., first printed in 1547, the following directions are given how a man should build his house or mansion; from which it appears that there were certain leading points for the guidance of the architect, founded, of course, they were on the habits of the time. "Make," says our friend Andrew, "the hall of such fashion that the parlor be annexed to the head of the hall, and the buttyre and pantrye at the lower ende thereof; the cellar under the pantrye sett somewhat at a base; the kechyn sett somewhat at a base from the buttyre and pantrye; coming with an entrie within, by the wall of the buttrie; the pastrie house and the larder annexed to the kechyn. Then divyde the logginges by the circuit of the quadrivial courte, and let the gatehouse be opposite, or against the hall doore; not directly, but the hall doore standinge abase of the gatehouse, in the middle of the front enteringe into the place. Let the preveye chamber be annexed to the great chamber of estate, with other chambers necessary for the buildinge; so that many of the chambers may have a prospecte into the chapell." Some of the principal innovations in the early Tudor style, were the introduction of gatehouses, bay windows, and quadrangular areas, matters rather incompatible with buildings constructed for defence. The materials of these palaces and mansions were of freestone and brick, according to the facility with which from the situation they could be procured. Sometimes, indeed often, these materials were mixed. Moulded brickwork and terra cotta were introduced for ornamental parts by Trevigi and Holbein towards the end of the period, or, perhaps strictly speaking, at the end of it. The brickwork was occasionally plastered and pointed as at Nonsuch. At Layer Marney and other places, bricks of two colours highly glazed were used for variegating the surface, and were formed into lozenges. The chimney shafts seem to have exhausted invention in the twisted and diapered patterns into which they were wrought, and decorated with heads and capitals and cognizances of the founders. The gateways were prominent features in these edifices, and the most expensive ornaments were lavished on them. That at Whitehall, designed by Holbein, was constructed with differently coloured glazed bricks, over which were appended four large circular medallions of busts, still preserved at Hatfield Peveril, Herts. This gateway contained several apartments, among which not the least remarkable was the study wherein Holbein chiefly received his sitters. The gateways at Hampton Court and Woolterton were very similar to this.

428. We will here digress a little on the bay window which, as generally understood, was simply a projecting window between two buttresses (whence its name, as occupying a bay of the building), and almost universally placed at the end of the room. It was invented about a century before the Tudor age, in which it usually consisted on the plan of right angles intersected by circles, as in the buildings at Windsor by Henry VIII., and at Thornbury Castle. When placed at the end of a great hall, it extended in height from the floor to the ceiling, and was very simple and regular in its form. In a MS. at the Herald's College relating to an entertainment given at Richmond by Henry VII., the following passage occurs, and may be taken as descriptive of one of the purposes to which it was applied. "Agaynst that his grace had supped: the hall was dressed and goodlie to be seene, and a rich cupboord sett thereup in a baye window of IX or X stages and haunces of hight, furnished and fulfilled with plate of gold, silver, and regilte." Carved wainscoting in

panels, generally of oak, lined the lower part of the halls with greater unity of design and execution than heretofore; and it now found its way into parlours and presence chambers with every variety of cyphers, cognizances, chimeras, and mottoes, which in the castles of France about the age of Francis I. were called *Boisseries*. Of these some curious specimens still remain in the hall and chambers of the dilapidated mansion of the Lords de La Warre at Halnaere in Suffolk. The area or court was quadrangular, and besides the great staircase near the hall, there were generally hexangular towers containing others: indeed, they were usually to be found in each angle of the great court, rising above the parapets, imparting a pleasant and picturesque effect to the mass of building, and grouping well with the lofty and ornamented chimneys of which we have above spoken.

FIG. 200. TUDOR ARCH, ST. GEORGE'S CHAPEL.

429. It is melancholy to reflect upon the disappearance of these mansions which were once the ornaments of the provinces, and now one by one falling fast away by the joint operation of what is called repair and by decay. Most of their remains have been removed to raise or to be incorporated with other buildings for which they might have well been spared.

430. The characteristics of the style are *arches*, universally flat, and wide in proportion to their height (fig. 200.). *Windows*, much more open than in the last period, flatter at the top, and divided in the upper part by transoms, which are almost constantly crowned with embattled work in miniature. The *ceilings* or vaultings spread out into such a variety of parts, that the whole surface appears covered with a web of delicate sculpture or embroidery thrown over it; and from different intersections of this ribbed work, clusters of pendant ornaments hang down, as Mr. Millers observes, like "stalactites in caverns." The *flying buttresses* are equally ornamented, and the external surfaces of the walls are one mass of delicate sculpture. The *ornaments*, as may be deduced from the above particulars, are lavish and profuse in the highest degree. Fretwork, figures of men and animals, niches and tabernacles, accompanied with canopies, pedestals, and traceries of the most exquisite workmanship, carried this style to the summit of splendour; and all these combined, had, perhaps, no small share in producing the extinction it was doomed to undergo.

431. Before proceeding to give the examples in this style, to which the reader will be referred, it may be as well to mention that Scotland boasts of many fine specimens of ecclesiastical architecture. The abbeys of Melrose and Kelso, founded by David I., as well as those in Dryburgh and Jedburgh, all in Roxburghshire, prove that the art advanced to as great perfection north of the Tweed, as it did in England. Roslin and Holyrood chapels, the first whereof was erected by Sir William St. Clair, for richness and variety of ornamental carvings cannot be exceeded. Its plan is without parallel in any other specimen of the fifteenth century. The latter was finished by James, the second of that name, in 1440, and is a beautiful example with flying buttresses, which are more ornamented than any even in England.

432. Examples of the Florid Gothic or Tudor style are to be seen at the cathedral churches — of *Gloucester*, in the chapel of Our Lady; at *Oxford*, in the roof of the choir; at *Ely*, in Alcock's chapel; at *Peterborough*, in Our Lady's chapel, and at *Hereford*, in the north porch. In conventual churches, at *Windsor*, St. George's chapel; at *Cambridge*, King's College chapel; at *Westminster*, King Henry VII.'s chapel; at *Great Malvern*, in Worcestershire, the tower and choir; at *Christ Church*, Oxford, the roof of the choir, and at *Evesham Abbey*, in Worcestershire, the campanile and gateway.

433. For parochial churches, except in some very few specimens in Somersetshire, and there perhaps only in parts, we are unable to refer the reader to a complete specimen, in all its parts, of the Tudor style. The pulpit and screen at Dartmouth, in Devonshire, are worthy of his notice.

434. We shall close this section by a tabular view of the founders and dimensions of the different cathedrals of England, extracted from Dallaway and other authors.

## BATH — CONVENTUAL CHURCH OF THE BENEDICTINES.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Tower.
		L. B. H.	L. B. H.	L. B. H.	L. B. H.	L. B. H.
1495 to 1502	Oliver King, bishop -	-	75 35 73	-	46 48 74	20 30 150
1532	Bird } priors - Gibbes }	136 72 78	-	Of the nave. 112 21 38	46 28 74	
1570	Inhabitants of Bath Sir John Harrington and others -	-	-	Of the choir. 80 21 38		
1609	James Montague, bishop	Completed the building				

Building unfinished at the Reformation, and completed by Bishop Montague and the executors of the Lord Treasurer Burleigh. Total length, 210 ft.; breadth, 126 ft.

## BRISTOL — CONVENTUAL CHURCH OF ST. AUGUSTINE.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Tower.
		L. B. H.	L. B. H.	L. B. H.	L. B. H.	Height.
1160 1230	Robert Fitzharding Robert third Lord					
1311 to 1332	Berkeley, Maurice fourth Lord Berke- ley, and Edmund Knowles, abbot -	75 73 43	Originally included.		128 - 43	
1463	Elliot and William Hunt, abbots -	-	100 - 43	-	N. trans.	127
1481 to 1500	John Newland, abbot, completed -	-	Our Lady's Chapel.			

The church displays two distinct styles. The Chapter House and Elder Lady Chapel were erected at the beginning and close of the twelfth century, and the existing nave and choir in the beginning of the fourteenth. It is probable it was not completed after the plan of the Abbot Knowles. The tower was intended to receive a spire. The aisles and nave are of the same height, which is only 43 ft.

## CANTERBURY — CATHEDRAL CHURCH.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Towers.
		L. B. H.	L. B. H.	L. B. H.	L. B. H.	
1070	Archbishop Lanfranc	-	-	-	-	N.W. 100 ft.
1090	Archbishop Anselme					
1100	Ernalphus } priors - Conrade }	The second church destroyed by fire in 1174.				
1122	Archbishop W. Corboil.					
1174	W. Senensis } archi- W. Anglus } tects {	Present } church. }	150 40 71	Included	Upper 154	
1304	Henry de Estrey, prior.					
1379 to 1431	S. Sudbury W. Courte- nay } arch- T. Arundel } bishops {	Improved and orna- mented. }	-	-	Lower 124	N.W. spire of lead added 100 ft. high; taken down 1705; S.W. 130 ft.
1449	T. Chittenden } priors T. Goldstone }	214 94 80				
1468	W. Sellinge.					
1490	W. Morton, archbishop	-	-	-	-	Central 234 high, 35 diameter.

The original Anglo-Saxon structure of Lanfranc was rebuilt after the canonisation of Thomas à Becket. The very elegant central tower was completed in 1500 by Archbishop Morton. This cathedral

has a lofty crypt of greater extent than, we believe, any other in England. At the eastern end of this cathedral, and projecting eastward of the general line of the plan, is an apartment open to the rest of the church, and consisting of a segment equal to about three fourths of a circle, called "Becket's Crown." The internal length of this church is 514 ft., and breadth 154 ft.,

## CARLISLE — CATHEDRAL CHURCH.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Towers.
	Bishops.	L. B. H.	L. B. H.	L. B. H.	L. B. H.	Height.
1150 {	Henry Murdac, abbot	82 - 71	-	Included.		
1270 {	of Fountains - }	Originally 164				
1353 {	Gilbert de Wilton,	-	137 - 71	71 - -	124 28 71	
1363 {	bishop - - }					
1363 {	T. de Apylby - -					
to 1397 {						
1400 {	Z. de Strickland -	-	-	-	-	128 ft.
to 1419 {						

The total length, 219 ft. ; breadth, 124 ft.

## CHESTER — CONVENTUAL CHURCH OF BENEDICTINES.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Tower.
		L. B. H.	L. B. H.	L. B. H.	L. B. H.	Height.
1128	Ranulf Earl of Chester					
1320	- - -	-	-	-	{ Transept dissimilar. North, a parish church. 180 - - }	
1485	Simon Ripley, abbot	{ - 73 73 }	-	-		127 ft.
	— Oldham, abbot }		-	-	-	
1508	- - -	{ The western front }	-	-	-	Finished in 1508.

The Chapter House was built by Ranulf Earl of Chester, and in it many of his descendants are interred. A north transept only in this church. Length, 348 ft. ; breadth, 180 ft.

## CHICHESTER — CATHEDRAL CHURCH.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Tower.
	Bishops.	L. B. H.	L. B. H.	L. B. H.	L. B. H.	
1094	Ralph - - -	First church.				
1125 {	Siffrede - - - Abbot of Glastonbury }	105 95 61	-	{ Included - 91 -		
1217	Ralph de Warham -		-	100 64 61	{ There are four aisles. The only instance in England. }	{ North }
1282	Gilbert de St. Leofard					
1329	John de Langton -	-	-	-	{ South, with window. }	{ 107 ft. high bell tower ; spire added to tower 271 ft. high.
1520	Robert Sherbourne -	Repairs and embellishment of the choir, &c.				

It may be right to consider the present church as founded by Siffrede upon that built by Ralph in 1094. Total length, 407 ft. ; width, 131 ft

## DURHAM — CATHEDRAL CHURCH.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Tower.
	Bishops.	L. B. H.	L. B. H.	L. B. H.	L. B. H.	
1093	William de Carilepho	260 74 69				
1128	Ralph Flambard.					
1230	Richard Poose and	-	-	Included.	176 57 -	
1233	Melsonby, prior	-	-	-	-	Western towers 143 ft.
	Bertram Middleton, } and Hugh Darling- } ton, priors - - }	-	120 74 71	-	90 18 -	
	Nicholas de Farnham, bishop.					
1295 {	Richard de Houton, } prior - - }	-	-	-	-	Central tower 214.

The Lady Chapel was built in 1390, forming a sort of transept at the end of the choir. This cathedral is remarkable from the pillars of its nave, which are curiously striated. The Galilee, or chapel, at the western end, is 50 ft. by 78 ft., and was finished by Bishop Langley in 1430. Total length of the church, 420 ft.; width, 176 ft.

## ELY — CATHEDRAL CHURCH.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Tower.	
	Bishops.	L. B. H.	L. B. H.	L. B. H.	Length.		
1109 to 1133	Herney -	-	-	-	N. 178½		
	Nigillus -	Erected the cloisters.					
1174	Id. Geoff. Ridal	203 - 104	-	-	-	{ Centre of West front 210 ft. high.	
1235 to 1252	Hugh Northwold	-	Presbytery, which was made the choir in 1769.				
1337	Simon Montacute	-	Octagon Louvre.				
	I. Wisbich, prior	-	101 34½ 70				

A spire of wood was added to the tower by Bishop Northwold, but it no longer exists; a gable built by Eustachius, a Bishop of Ely. The octagon, from which rises the louvre, is 142 ft. high from the floor, and is 71 ft. 6 in. diameter. It was designed by Alan de Walsingham, a monk of Ely, in 1328. The diameter of the lantern is 30 ft., and its external height 170 ft. Total length, 517 ft.; breadth, 178 ft. 6 in.

## EXETER — CATHEDRAL CHURCH.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Tower.
	Bishops.	L. B. H.	L. B. H.	L. B. H.	L. B. H.	L. B. H.
1100 } to } 1128 }	W. Warlewast -	-	-	-	-	28 28 145
1280 } to } 1293 }	Peter Quivil -	-	-	-	140 32 68	
1293 } to } 1307 }	Thomas Bytton -	180 40 68	-	148 20 35		
1307 } to } 1318 }	Walter Stapylton -	-	132 34 68	132 20 35		
1340	Edmund Lacy -	-	Built the chapter house.			

The cloisters, which are only perfect on one side, were added by Thomas Brentinghan. The towers stand at the ends of the transept. The general plan of the church is that designed by Bishop Quivil, from which none of his successors deviated. The total length is 390 ft.; width, 140 ft. Bishop Grandison's screen in this cathedral is celebrated among antiquaries as displaying a series of statues more numerous and entire than are to be found in any other cathedral.

## GLOUCESTER — CONVENTUAL CHURCH OF BENEDICTINES.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Tower.
		L. B. H.	L. B. H.	L. B. H.	L. B. H.	L. B. H.
1057 to 1089	Aldred, Bishop of Worcester -	171 41 67½				
1089	Id. - - -	-	-	N. 171 21 40½		
1310	Abbot, J. Thokey	-	-	S. 171 22 -		
1330	Abbot, J. Wygmore	-	-	-	S. 66 43½ 78	
1330 to 1357	Adam Staunton to Walter Frocester, and to Thomas Sebroke - -	Clerestory and vaulting.	140 34½ 86			
1369 to 1375	Ut supra - -	-	-	-	N. 66 43½ 78	
1457 to 1518	W. Ferleigh to Thomas Bramish, and to W. Parker -	-	-	-	-	24 22 224

The Lady Chapel was built by W. Ferleigh about 1498. The western façade and two arches were added to the nave about 1370 by T. Horton. The tower rises from the intersection of the nave and choir with the transepts. The cloisters are the most perfect and beautiful of any in England, and are unusually situated, being on the north side of the church. Total length, 426 ft.; width, 152 ft.

## HEREFORD — CATHEDRAL CHURCH.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Tower.
	Bishops.	L. B. H.	L. B. H.	L. B. H.	L. B. H.	
1079 to 1095	Robert de Losinge	144 68 68	-	144 - -	140 - -	
1101 to 1115	Rainelm -	-	125 20 64			
1131 to 1148	Robert de Bethune, prior of Llanthony	-	-	-	Lower. 111 - -	Ancient spire 240 ft. high. West tower was 130 ft. The spire, which was taken down in 1790.
1200 to 1216	Giles de Bruse	-	-	-	-	
1492 to 1502	Edmund Audley	-	-	-	-	
Restored in 1786.						

The great west tower fell in 1786, and destroyed the greater part of the nave and aisles, which were rebuilt shorter by 15 ft. The architecture of the chapter house, which was octagonal, with a single central pillar, and 37 ft. diameter, was unnecessarily taken down by Bishop Egerton. Total length, 325 ft.; width 100 ft.

## LICHFIELD — CATHEDRAL CHURCH.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Tower.
		L. B. H.	L. B. H.	L. B. H.	L. B. H.	
1295 to 1430	Bishops. Walter de Louton, or Langton - - And his successors - William Hewworth, who died in 1447 -	213 67 67 W. front. 78 - -	120 33 67 -	Included. -	88 - - -	West spires 183 ft. high. Total of the central spire. 258.

The church is very uniform, having been, like Salisbury and Exeter, completed upon one plan. The arches in the Triforia here show the dog-tooth moulding in great perfection. Total length, 411 ft.; breadth, 88 ft.

## LINCOLN — CATHEDRAL CHURCH.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Towers and Spires.	
	Bishops.	L. B. H.	L. B. H.	L. B. H.	L. B. H.		
1184	{ Alexander Nor- mannus - - }	Rebuilt.					
1186 to 1200	{ Hugh de Grenoble	240 80 80	140 40 72	Included.			
1240	Robert Grosstête						
1254	Henry Lexington -	-	-	-	-	{ Central 288 ft high W. 260 ft. W. fron 173 ft. wide 83 ft. high.	
1286 to 1300	{ Hugh Burgundus	-	Presbytery.	-	W. 220 63 74		
1306	John D'Alderby -	-	106 82 72	-	E. 166 63 72		
1438	William Alnewick -	Built the great west window and porch.					

The central spire of this cathedral was higher than that of Salisbury, and was blown down in 1547.

The others were removed in 1808. Total length, 498 ft.; breadth, 227 ft.

## LONDON — OLD ST. PAUL'S CATHEDRAL CHURCH.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Towers.
	Bishops.	L. B. H.	L. B. H.	L. B. H.	L. B. H.	
1086	Mauritius -	335 91 102				
1120	Richard de Beaumes -	-	-	Included.	297 - -	{ Height 260 ft., ditto of spire 274 ft. Burnt down in 1561.
1220	William de St. Maria -	-	163 - 88	-	-	

The Chapter House was built by William de St. Maria, and was octangular. The cloisters, which were only 91 ft. square, were erected by Henry de Wingham in 1260; and the Lady Chapel by Henry de Lacy, Earl of Lincoln, in 1312. The area which this cathedral covered in 1309 was 3 acres, 3 roods, and 26 perches. The cloisters were removed by the Protector Somerset, to build his palace in the Strand. Inigo Jones commenced his restorations upon the fabric in 1633, and placed, in 1636, a most beautiful but incongruous Corinthian portico at the western end, the expense of which was borne by Charles I. The whole of the church was taken down and removed by Sir Christopher Wren in 1675. The church was rebuilt in the following style: — Length, 631 ft.; breadth, 130 ft. The tower, 188 ft. of the tower, 264 ft. high, is a most interesting work, with lead, 274 ft. Dugdale's history of the church is a most interesting work, and is a most interesting work.

## NORWICH — CATHEDRAL CHURCH.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Tower.
	Bishops.	L. B. H.	L. B. H.		L. B. H.	
1096	Herbert Losinga -	-	-	-	-	Tower
1171	Eborard -	140 71 -	-	-	-	
1197	John of Oxford -	-	165 - -	Included.	191 - -	
1361	{ Ralph Walpole Thomas Percy }	-	-	-	-	Spire 317 ft.

This church has no Lady Chapel. The cathedral, before 1272, was so dilapidated, that it was nearly rebuilt by succeeding bishops and priors. The cloisters, erected by Bishop Wakering in 1420, are the most spacious in England, being 174 ft. square. Length of cathedral, 414 ft.; breadth, 191 ft.

## OXFORD — CONVENTUAL CHURCH OF ST. FRYDESWIDE AUG. CANONS.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Tower.
		L. B. H.	L. B. H.		L. B. H.	
1050	{ Guymond, prior of	74 54 41½	80 37 -	Included.		
1120	{ St. Frydeswide }	-	-	-	102 - -	Tower.
1122	-	-	-	-	-	
1528	Cardinal Wolsey -	-	Clerestory	-	-	Spire.
1545	Robert King, first bishop	-	-	-	-	

The Chapter House here is of perfect Anglo-Norman architecture, built in the reign of Henry II. Length of church, 154 ft.; breadth, 102 ft.

## PETERBOROUGH—CONVENTUAL CHURCH OF THE BENEDICTINES.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Tower.
		L. B. H.	L. B. H.		L. B. H.	
1160 tem. Hen. II.	William de Watteville, 21st abbot - - }	-	138 78 78			
1175	Benedict, 22nd abbot -	231 78 -	-	Included.		
1272	Richard de London, 32nd abbot - - }	-	-	-	203 69 78	
1295	William de Parys, prior					
1300	or W. de Woodford, abbot - - }	-	-	-	-	Two spires 156 ft. high.
1330	Geoffrey Croyland, 34th abbot - - }	-	-	-	-	Unfinished tower, 120 ft. Louvre, 150 ft.
1496	Robert Kirton, 44th abbot, built the chapels at the end of the choir.					

Length, 480 ft. ; breadth, 203 ft.

## ROCHESTER—CATHEDRAL CHURCH.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Tower.
		L. B. H.	L. B. H.		L. B. H.	
1080	Bishops. Gundulphus - -	150 75 -	-			
1115	Ernulph - -	-	-	-	122 - -	
1227	Henry Sanford - -	-	156 - -	Included.	-	Spire, 156 ft.
1270	W. de Hoo, prior, built a chapter house.					

When the choir was rebuilt, in 1227, it was extended to a greater length by several feet than the nave itself. The choirs of Norman churches were all disproportionately short. Total length, 306 ft.; breadth, 122 ft.

## SALISBURY—CATHEDRAL CHURCH.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Tower.
		L. B. H.	L. B. H.		L. B. H.	
1217	Bishops. Richard Poore - -	229 76 81	-	-	-	To the Pa- rapet, 207 ft.
1230	Robert Bingham - -	-	140 - 84	Included.		
1274	Robert Wykehampton	-	-	-	230 60 84	Spire, 404 ft.

This is the most uniform of the cathedrals of England. It was ascertained, in 1737, that the roof altogether contained 2641 tons of timber. According to the account delivered to Henry III., it appeared that 40,000 marks (22,666l. 13s. 4d.) had, up to that time, been expended on the fabric. The original plan was given by Bishop Poore, and from that time it was made by his successors. The church was twice consecrated. The choir is 140 ft. long, with a central column, and the cloisters are 160 ft. square. The nave is 229 ft. long, and the width of the choir seems to be scarcely adequate to support its own weight. The tower is 122 ft. high, and the western front is 112 ft. wide. Great repairs were made in 1737, and the western front was then rebuilt.

## WELLS—CATHEDRAL CHURCH.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Tower.
		L. B. H.	L. B. H.		L. B. H.	L. B. H.
1205 to 1239	Bishops Josaline Troteman -	191 67 67	108 67 -	Included.	135 - 67	
1293	W. de March					
1366	John Harwell					
1450	Thomas Beckington -	-	-	-	-	Western. 234 - 130
1465	Robert Stillington -	-	-	-	-	Central. - - 160

This is a very extraordinary example. Its western façade is decorated with statues in a more perfect state than is seen in any cathedral excepting that of Lincoln. The subjects are kings, bishops,

and warriors. The original plan seems to have been strictly followed to its completion by Bishop Stillington. Speed says that Ralph de Shrewsbury, who died in 1363, was a great benefactor to the church, and prosecuted the original plan. The support of the central tower is assisted by the principle of the inverted arch as at Salisbury, and is a good example of constructive skill. Total length, 371 ft.; breadth, 185 ft.

## WESTMINSTER — CONVENTUAL CHURCH.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Tower.
1250	King Henry III.	L. B. H. 166 38 101	L. B. H. 155 38 101	L. B. H. 166 16 101	L. B. H.	Height to the top of the western turrets, addition 102½ ft., 225 ft. in the whole.
1300	King Edward I.	Extreme breadth of the Nave and Aisles, - 71½ -	-	-	136 40 78	
1490	King Henry VII.	{ Chapel, 103 ft. long, 35 ft. broad, 60 ft. high; aisles, 62 ft. long, 17 ft. broad.				

The Choir of Henry VII. is among the most beautifully decorated in England. The choir is decorated with a range of windows in the back wall, which are seen external to the choir, the choir, inscribed within a triangle, equilaterally composed of three, and the choir was Thomas Fitz-Otho, the king's Master of the Mint.

## WINCHESTER — CATHEDRAL CHURCH.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Tower.
	Bishops.	L. B. H.	L. B. H.		L. B. H.	
1070	Wakelyn - - -	-	-	-	186 - -	150 ft. high.
1190	Godfrey de Laci, the Cloisters					
1350	William de Edynton, the Lady Chapel					
1394	William de Wykeham -	300 86 78				
1493	Cardinal Beaufort -	-	Presbytery	Included.		
	T. Langton - - -	-	93 86 78			

The western front was finished by Edynton. The nave, which was finished by William of Wykeham, is longer than that of York, and considered one of the finest in England. The exterior of the choir is of the finest Gothic of the fifteenth century. The choir, as at Gloucester, is under the tower. Total length, 545 ft.; breadth, 186 ft.

## WORCESTER — CATHEDRAL CHURCH.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Tower.
	Bishops.	L. B. H.	L. B. H.		L. B. H.	
1218 to 1224	William de Blois -	212 78 72	80 36 61	Included.	Lower, 128 32 -	172 ft. high.
1327	T. Cobham, Lady Chapel					
1372	W. de Lynne - - -	-	-	-	-	
1374 to 1380	Henry Wakefield -	-	-	-	Upper, 120 25 -	

The Choir of the Cathedral of Worcester is 120 ft. long and 125 ft. in breadth, were erected in the reign of William I. The choir of the church was built before 1150, and parts of it may still be traced. The choir of the convent, 120 ft. by 38 ft., is still perfect. The nave is, for its length and proportion, well adapted to the attention of the student. The total length of the church is 410 ft.; its breadth, 130 ft.

## YORK — CATHEDRAL.

Dates.	Founders.	Nave.	Choir.	Aisles.	Transept.	Tower.
	Archbishops.	L. B. H.	L. B. H.	L. B. H.	L. B. H.	
1227	Walter Grey -	-	-	-	222 - 103	
1291	John Romain -	250 103 92	-	250 - 47		
	W. de Melton -	-	-	-		{ Façade and western towers 196 ft.
1361	J. Thoresby -	-	150 43 101	-	-	
1300 } to } 1420 }	J. Birmingham, treasurer, completed the façade -	-	-	-	-	{ L. B. H. Central. 44 42 182

Octagonal Chapter House, erected by W. de Melton. The foundations of the church were laid in 1171, by Roger, the archbishop. The central lantern or steeple, built by Le Romain, was taken down in 1350 by Walter Skelton. The aisles surround the church in every part, are of similar dimensions, and were built at the same time. The open central tower, or louvre, is 188 ft. from the floor. The Rose Window, the finest in England, is 22 ft. 6 in. diameter. Total length, 498 ft.; breadth, 222 ft.

435. The following synoptical view of the general dimensions of the above cathedrals, we think, may prove occasionally useful to the reader, by enabling him to compare the whole of them and their parts with each other. The equality of the proportions is striking; and, in another part of this work, we hope to place before the reader some principles which tend to prove that there was a much more established practice founded on the laws of statics than has hitherto been conjectured. Dallaway, without the remotest idea of the principles in question, has observed, with his usual sagacity, that there appears in them "a distribution of parts which will hold almost generally, that the width of the nave is that of both the aisles, measured on the plan to the extremity of the buttresses externally; and that the breadth and height of the whole building are equal. In the more ancient churches, the aisles are usually of the width of the space between the dividing arches." Some idea of the principle is conveyed in the plates of Milan cathedral, curiously introduced into the very early translation of *Vitruvius* by Cæsar Cæsarionus, a work of great curiosity, and of which copies are now rarely met with.

## A SYNOPTICAL VIEW OF THE LEADING DIMENSIONS OF THE ENGLISH CATHEDRALS.

Cathedral.	Total internal Length.	Naves and Aisles.			Choirs.			Transepts	Spires and Towers.		
		Length.	Breadth.	Height.	Length.	Breadth.	Height.	Breadth.		Height.	
Winchester -	545	247	86	78	138	-	73	186

## Breadths of Naves and Aisles.

Norwich - 71 ft.

Bristol	- 73	Canterbury	- 74 ft.	Peterborough	78 ft.	Lincoln	- 83 ft.
Chester	- 73	Exeter	- 74	Worcester	- 78	Gloucester	- 84
Ely	- 73	Salisbury	- 76	Durham	- 80	Winchester	- 85

The author just quoted, in reference to the tables here given, says of them, that "the parallel will afford us, at one view, authentic information concerning the proportion of one constituent part to another of every cathedral in England which is worthy the notice of an architect. Such," he continues, "a coincidence of dimensions as that which is found in many of them, can scarcely be supposed to be the effect of chance, especially where the buildings are contemporary and of an exactly correspondent style." It appears that the equality of proportions is confined to each era and style of ecclesiastical architecture in so remarkable a degree as to lead us to conjecture that they might have been designed by the same architect. "The constant rivalry," says Dallaway, "which subsisted between the magnificent prelates, was excited upon the erection of any part of a cathedral of superior beauty, and imitated in those of the same kind which were then undertaken; and the architect who had once displayed great talents was invited to repeat the more perfect performance, upon which he had rested his professional fame." We have not considered it necessary to devote a special portion of our work to the conventual architecture of England, because it followed the style of the time. It was of great splendour. The ground plans of their habitable portions were usually, though not always, quadrangular, and in the later ages partook of the improvements in domestic architecture, as in the colleges built by Wykham and Waynflete, and many of the episcopal residences. Glastonbury and Reading presented exceedingly fine examples of it; the former comprised within its walls sixty acres of ground.

## SECT. VI.

## ELIZABETHAN ARCHITECTURE.

436. The revival of the arts in Italy has furnished the subject of Chap. II. Sect. XVI. It commenced, as we have there seen, with its author Brunelleschi, who died in 1444; and it was not till more than a century afterwards that, notwithstanding our constant intercourse with the Continent, its influence began to be felt in this country. The accession of Elizabeth, it will be recollected, took place in 1558.

437. Whilst the art was in the hands of the clergy, though here always, in point of time, behind that of the Continent, it flourished vigorously; but when that body was scattered by the dissolution of the religious houses, no one remained to foster it; and though Henry VIII. delighted in *spectacle*, and a gorgeous display of his wealth, he was far too great a sensualist to be capable of being trained to refinement in the arts. Neither, moreover, are the English, as a people, susceptible of high feeling in respect of the productions of art. Even to the present hour so low in the scale do they stand, that a lady's cap finds no adoption, receives no sanction among the higher classes, unless moulded and previously sanctioned in the capital of our lively neighbours. In short, the only period in which the arts seemed likely to take root here was under that unfortunate monarch Charles I.; since whose time they have languished, giving way to politics, which engross the attention of the higher class, and to commerce, which occupies the attention of the merchants. There is here no general pervading love of the arts, as among all classes on the Continent, though we believe the time for it approaches. The Elizabethan, or, as some have, perhaps more properly, called it, the last Tudor style, is an imperfectly understood adaptation of classic forms to the habits of its day in this country. It is full of redundant and unmeaning ornament, creating a restless feeling in the mind of the spectator, which, in the cinque cento work, the renaissance of Italy, was in some degree atoned for by excellence of design, by exquisite execution of the subject, and by a refinement in the forms which some of the first artists the world ever saw gave to its productions. In Italy, the orders almost

instantaneously rose in their proper proportions, soon leaving nothing to be desired ; but in England they were for a long time engrafted on Gothic plans and forms, producing nothing but heterogeneous masses of absurdity. It was, nevertheless (strange to say), in this style and the Gothic, that the wisdom of the legislature thought proper to solicit designs from the architects of the country, in the year 1836, for new houses of Parliament, a proceeding which has excited the smiles of the artists of the Continent at our absurdity in matters of art.

438. The work of Andrew Borde has been before mentioned ; but the earliest publication in England relative to practical architecture was, "The first and chiefe Grounds of Architecture used in all the ancient and famous Monyments, with a farther and more ample Discourse upon the same than has hitherto been set forth by any other. By John Shute, paynter and architecte." "Printed by John Marshe, fol., 1563." This John Shute had been sent by Dudley, Duke of Northumberland, to Italy, probably with the intention of afterwards employing him upon the works which he was projecting. From this and many other circumstances, it is easy to discover that domestic architecture under Elizabeth had assumed a more scientific character. Indeed, there is ample evidence that no building was now undertaken without the previous arrangement of a digested and regulated plan ; for early in the reign of this sovereign the treatises of Lomazzo and Philibert de Lorme were translated into English ; and in the construction of the palatial houses of the aristocracy, the architects had begun to act upon a system. The principal deviation from the *plans* of the earlier Tudor houses was in the bay windows, parapets, and porticoes, whereof the two latter were intensely carved with all the forms that the most fantastic and grotesque imagination could supply. The exteriors of these porticoes were covered with carved entablatures, figures, and armorial bearings and devices. The galleries were lofty, wide, and generally more than a hundred feet in length ; and the staircases were spacious and magnificent, often occupying a considerable portion of the mansion. Elizabeth herself does not appear to have set, during the passion of the period for architecture, any example to her subjects. She might have thought her father had done sufficient in building palaces ; but, however, be that as it may, she encouraged the nobles of her court in great expenditure on their residences. With the exception of the royal gallery at Windsor, she herself did actually nothing ; whilst on Kenilworth alone, Lord Leicester is supposed to have expended no less a sum than 60,000*l.*, an almost royal sum of money.

439. Before proceeding further, it becomes our duty here to notice a peculiar construction which prevailed in the large manor houses of the provinces, and more especially in the counties of Salop, Chester, and Stafford, the memory of many whereof, though several are still to be seen, is chiefly preserved in engravings ; — we allude to those, of timber framework in places where the supply of stone or brick, or both, was scanty. The carved pendants, and the barge-boards of the roofs and gables, which had, however, made their appearance at a rather earlier period, were executed in oak or chesnut with much beauty of design, and often with a singularly pleasing effect. The timbered style reached its zenith in the reign of Elizabeth, and is thus illustrated in Harrison's description of England : — "Of the curiousnesse of these piles I speake not, sith our workmen are grown generallie to such an excellence of devise in the frames now made, that they farre passe the finest of the olde." And, again : "It is a worlde to see how divers men being bent to buildinge, and having a delectable view in spending of their goodes by that trade, doo dailie imagine new devises of their owne to guide their workmen withall, and those more curious and excellent than the former." (p. 336.) The fashion was no less prevalent in cities and towns than in the country ; for in them we find that timber-framed houses abounded, and that they also were highly ornamented with carvings, and exhibited in their street fronts an exuberance of extremely grotesque figures performing the office of corbels. The fashion was imported from the Continent, which supplies numberless examples, especially in the cities of Rouen, Bruges, Ulm, Louvaine, Antwerp, Brussels, Nuremberg, and Strasburg, which very far surpass any that this country can boast. We have, however, sufficient remains of them in this country to prove that the wealthy burgess affected an ornamental display in the exterior of his dwelling, rivalling that of the aristocracy, and wanting neither elegance nor elaborate finishing, whilst it was productive of a high picturesque effect in the street architecture of the day. "This manner," says Dallaway, "was certainly much better suited to the painter's eye than to comfortable habitation ; for the houses were lofty enough to admit of many stories and subdivisions, and being generally placed in narrow streets were full of low and gloomy apartments, overhanging each other, notwithstanding that they had fronts nearly composed of glass, with the projecting windows and the interstices filled for nearly the whole space." *Fig. 201.* is a representation of Morton Hall, an example of the style in question.

440. A better idea of the architecture of this age cannot be obtained than by a notice of the principal architects who have furnished materials for the foregoing observations ; and for this purpose we shall use with freedom the notes to Walpole's anecdotes, by our late much valued friend Mr. Dallaway. A MS., belonging to the Earl of Warwick

Fig. 201.

TIMBER-FRAMED HOUSE, MORTEN HALL

in the time of Walpole, enabled him to bring to the knowledge of the world, and perpetuate the memory of, an artist of no mean powers, whose name, till that author's time, was almost buried in oblivion, though he was the architect of most of the principal and palatial edifices erected during the reigns of Elizabeth, and James, her successor. His name was John Thorpe; and at the sale of the library of the Hon. Charles Greville in 1810, the MS. in question came into the possession of the late Sir John Soane, Professor of Architecture to the Royal Academy. It is a folio, consisting of 280 pages, wherein the plans, often without a scale, are nevertheless accurately executed. Several of the subjects were merely designs for proposed mansions. The elevations are neatly drawn and shadowed. The general form of the plans is that of three sides of a quadrangle, the portico in the centre being an open arcade finished by a turreted cupola. When the quadrangles are perfect, they are, for convenience, surrounded by an open corridor. The windows, especially in the principal front, are large and lofty, and mostly alternated with bows or projecting divisions, and always so at the flanks. The ornaments are of the cinque cento school, as far as it was understood here, and are universally rude imitations of the works of Lescot and Vignola, — of the latter, of course, much debased. Great efforts were made by Thorpe to group the chimneys, which were embellished with Roman Doric columns, and other conceits. The contents of the volume are as follow : —

1. The ground plan of Old Somerset House.
2. Buckhurst House in Sussex, whereof are a ground plan and elevation. The front extends 230 ft. The quadrangle is 100 ft. by 80 ft., and the hall 80 ft. by 50 ft.
3. (Page 24.) The garden front of a nobleman's house, probably only a design.
4. "The way how to drawe any ground plot into the order of perspective," with diagrams and written descriptions.
5. A design for a large house with three sides of a quadrangle.
6. An elevation of a house for Sir Thomas Dorrell in Lincolnshire.
7. Godstone. An open corridor of the Doric order.
8. Copthall in Essex, built for Sir Thomas Heneage, to whom the manor was granted by Queen Elizabeth. The gallery, of extraordinary length, as compared with its height and width, was 168 ft. long, 22 ft. high, and the same wide; and the inner court of the mansion was 83 ft. square.
9. Wollaton Hall, Nottinghamshire, the inscription whereon runs thus: "*En has Francisci Willoughbei Aedes, rara arte constructas Willoughbæis relictas. Inchoate, 1580—1588.*" Mr. Dallaway observes, on this inscription, that the monument of Robert Smithson in Wollaton Church appears to invalidate Thorpe's claim to this design. It runs thus: "Mr. Robert Smithson, architector and surveyor unto the most worthy house of Wollaton, with divers others of great account, ob. 1614." He was probably Thorpe's pupil and successor.

10. A design of a quadrangle intersected by a corridor.
11. Sir John Bagnall's house, with a gallery above 60 ft. in length.
12. Burleigh House, built for Cecil the Lord Treasurer: but it exhibits only the plans of the ground and first floors, with designs and sketches for the scroll parapet.
13. Some details for Sir George St. Poole.
14. Thornton College, with a gallery 100 ft. long, for Sir Vincent Skinner.
15. A ground plan for Sir Thomas Holte.
16. A design.
17. The house called Holland House, at Kensington, for Sir Walter Coopes. This was finished by Thorpe in 1607, and afterwards received alterations and additions from the hands of Inigo Jones and Stone.
18. Giddea Hall, Essex; altered for Sir Anthony Coke, who there entertained Queen Elizabeth.
19. For Sir George Coppen.
20. Burghley on the Hill. Garden front.
21. "A front or garden side for a nobleman, three breadths of ordinary tenements;" supposed to have been for Sir Robert Greville's (Lord Brooke) house, near Gray's Inn.
22. "A London house for Mr. Darby."
23. Wimbledon. "A house stands upon the edge of a hill," built for Sir Thomas Cecil in 1588. Fuller says it was nearly equal to Nonsuch. It was rebuilt by Sarah Duchess of Marlborough, and was consumed by fire.
24. "Queene Mother's House," altered by I. Thorpe.
25. "Monsieur Jammet in Paris, his house, 1620. All his offices are under ground."
26. Jannin's house, five leagues from Paris, an. 1600.
27. An elevation for Sir William Haslerigg.

Fig. 202.

LONGFORD CASTLE.

28. Longford Castle, Wiltshire (*fig. 202.*). A most singular production. A diagram of the Trinity drawn in the centre of a plan of the triangular court. It was erected for Sir Thomas Gorges and his lady, the Marchioness Dowager of Northampton, in 1591, and is now the seat of the Earl of Radnor.
29. A plan for Sir Percival Hart, Lullingstone, Kent.
30. A house for Mr. Panton.
31. Holdenby, built for Sir Christopher Hatton in 1580, and now in ruins. Two large quadrangles in the plan, and an elevation of the front.
- 32 and 33. Plans for Mr. William Fitzwilliam and Sir Henry Neville.
34. Audley End; plan of the two courts. Thorpe's part completed about 1616. Much reduced in size since, and now the property of Lord Braybrooke.
35. A design.
36. Mr. Taylor's house at Potter's Bar.
37. Sir Walter Covert's in Sussex, whereof the ruined walls are still standing.
38. Hatfield Lodge, a plan.
- 39 and 40. Drawings relating to Ampthill.
41. "Kirby, whereof I laid the first stone." This was a house for John Kirby, citizen of London, whose death is mentioned by Fleetwood, Recorder of London, in a letter to the Lord Treasurer Burleigh. He had built a fair house on Bethnal

Green, whose loftiness and similitude to a castle, caused some ridicule of him by the rhymesters of the day

441. Walpole, upon *Thorpe's Compositions*, observes, that the taste of this master's mansions was that "bastard style which intervened between Gothic and Grecian architecture, or which, perhaps, was the style that had been invented for the houses of the nobility when they first ventured, on the settlement of the kingdom after the termination of the quarrel between the Roses, to abandon their fortified dungeons, and consult convenience and magnificence." The same author continues, "Thorpe's ornaments on the balustrades, porches, and outsides of windows are barbarous and ungraceful, and some of his vast windows advance outwards in a sharp angle; but there is judgment in his disposition of apartments and offices, and he allots more ample space for halls, staircases, and chambers of state. He appears, also, to have resided at Paris, and even seems to have been employed there." Among the designs he made is that of a whimsical edifice, designed for himself, forming on the plan the initial letters of his name **HT**, which are joined by a corridor, the **H** being the situation of the offices, and the **T** being skilfully distributed into large and small apartments. The epigraph to the design is as follows:—

"Thes 2 Letters **H** and **T**"

"Joynd together as you see"

"Is meant for a dwelling house for mee"

"JOHN THORPE"

Walpole truly observes of this volume, that "it is a very valuable record of the magnificence of our ancestors, and preserves memorials of many sumptuous buildings of which no other monument remains." We ought, perhaps, to have suffered our account of Thorpe to have been preceded by those of others, but the conspicuous rank he holds in the list of English architects of this period induced us to place him before another, for a little time his predecessor in the works of the country. We allude to the name of Robert Adams, who translated Ubal dini's account of the defeat of the Spanish Armada from the Italian into Latin; a feat which we fear but few architects of the present day would easily accomplish, such is the fall of education for artists, notwithstanding all the boasts of march of intellect. This translation appeared in 4to., 1589. He was surveyor of the queen's buildings, and appears to have been a man of considerable ability. His place of sepulture was in an aisle on the north side of the old church at Greenwich, with this inscription, "Egregio Viro, Roberto Adams, operum regiorum supervisor architecturæ, peritissimo, ob. 1595. Simon Basil, operationum regiarum contrarotulator, hoc posuit monumentum 1601."

Fig. 215

WOLATON HALL.

442. Bernard Adams and Lawrence Bradshaw were also eminent among the architects of the period under our consideration; but we must notice more particularly Gerard Christmas, who was associated with Bernard Jansen in the erection of Northampton, afterwards Suffolk, and now Northumberland House, not strictly belonging in time, though in style, to the reign of Elizabeth. Both of these architects had acquired considerable fame, and were, deservedly, much employed. In Northumberland House the cyphers of Christmas, C. Æ. (Christmas ædificavit), were used in the street front. The letters H. N. were originally in the balustrade here, standing for Howard Earl of Northampton, and were frequently repeated, a practice then much in vogue, for there are many examples of inscriptions of letters enclosed within the balustrade, as if within lines, and pierced so that the sky seen through them renders them distinct from almost every point of view. Bernard Jansen was probably the architect first employed at the splendid mansion of Audley Inn in Essex, for Thomas Howard Earl of Suffolk; and, besides the association with Christmas above mentioned, was joined with Moses Glover in completing Northumberland House, and was probably the architect who finished Sion House in Middlesex, for Henry Earl of Northumberland, who had at the time expended 9000*l.* in the work.

443. Robert and Huntingdon Smithson, father and son, were engaged on Wollaton Hall (*fig.* 203. at the foot of the preceding page), in Nottinghamshire, as also at Bolsover in Derbyshire. The former died in 1614, at the age of seventy-nine, and the latter in 1648, but it is pretty certain that Thorpe was consulted in this splendid work, for among his designs, as the reader will recollect, are some for Wollaton.

444. Thomas Holte, a native of York, was the architect of the public schools at Oxford

*Fig.* 204.

PUBLIC SCHOOLS AT OXFORD.

(*fig.* 204.), of which the hint might have been taken from the Campanile of Santa Chiara at Naples, and of the quadrangles of Merton and Wadham colleges. He was the first in this country who introduced the classical orders in series above each other. He evidently borrowed the practice from Philibert Delorme, who had done the same thing at the Chateau d'Anet, near Paris, one of the victim edifices of the Revolution. We apprehend any argument to prove the absurdity of such conceits is unnecessary.

445. Many of the grandest works of what is termed the Elizabethan, or, in truth, the

last Tudor style, were not completed before the middle of the reign of James I. ; so that it may be said to have been practised until the days of Inigo Jones, in whose early works it may be traced. " This fashion," says Dallaway, " of building enormous houses was extended to that period, and even to the civil war. Audley Inn, Hatfield, Charlton, Wilts, and particularly Wollaton, are those in which the best architecture of that age may be seen. Others of the nobility, deserting their baronial residences, indulged themselves in a rivalry in point of extent and grandeur of their country-houses, which was, of course, followed by opulent merchants, the founders of new families. Sir Baptist Hicckes, the king's mercer (afterwards ennobled), built Campden House, Gloucestershire, which was scarcely inferior to Hatfield, afterwards burnt down. There is scarcely a county in England which cannot boast of having once contained similar edifices ; a very few are still inhabited ; others may be traced by their ruins, or remembered by the oldest villagers, who can confirm the tradition ; and the sites, at least, of others are pointed out by descriptions as having existed within the memory of man."

446. The following is a list of some of the principal palatial houses finished before 1600. Others of the reign of Elizabeth's successors will hereafter be noticed. Of so many of them are the names of the architects undetermined, though many are assigned to those we have already mentioned, that we shall not attempt to assign a column to the artists in question, for fear of misleading our readers.

Name.	Date.	County.	Founder.	Present State.
Catledge - -	1560	Cambridge	Lord North - -	Taken down.
Basinghouse - -	-	Hants -	Marquis of Winton - -	In ruins.
Kelston - -	-	Somerset -	Sir J. Harrington - -	Rebuilt.
Gorhambury - -	1565	Herts -	Sir N. Bacon - -	In ruins.
Buckhurst - -	-	Sussex -	Lord Buckhurst - -	Destroyed.
Knowle - -	1570	Kent - -	Lord Buckhurst - -	Perfect.
Penshurst - -	-	Kent -	Sir H. Sydney - -	Perfect.
Kenilworth - -	1575	Warwick -	Earl of Leicester - -	In ruins.
Hunsdon - -	-	Warwick -	Lord Hunsdon - -	Rebuilt.
Wanstead - -	1576	Essex -	Earl of Leicester - -	Destroyed.
Burleigh - -	1577	Lincoln -	Lord Burleigh - -	Perfect.
Osterley - -	-	Middlesex -	Sir Thomas Gresham - -	Rebuilt.
Longleat - -	1579	Wilts -	Sir J. Thynne - -	Perfect.
Stoke Pogis - -	1580	Bucks -	Earl of Huntingdon - -	Rebuilt.
Toddington - -	-	Beds -	Lord Cheyney - -	Destroyed.
Theobalds - -	-	Herts -	Lord Burleigh - -	Destroyed.
Wimbledon - -	1588	Surrey -	Sir T. Cecil - -	Rebuilt.
Westwood - -	1590	Worcester -	Sir J. Packington - -	Perfect.
Hardwick Hall - -	1597	Derby -	Countess of Shrewsbury - -	In ruins.

447. Relative to Osterley, in the above table, a curious anecdote has been preserved by Fuller, in his *Worthies of Middlesex*. Queen Elizabeth, when visiting its magnificent merchant, the owner, observed to him that the court ought to have been divided by a wall. He immediately collected so many artificers, that before the queen had risen the next morning, says the historian, a wall had been actually erected.

448. Many of these houses possessed terraces of imposing grandeur, which were connected by broad or double flights of steps, with balustrades, whereof, if we may judge from Winstanley's print of Wimbledon, the seat of Sir Edward Cecil, it was a very fine example. The following extracts from the parliamentary survey of it in 1649 will convey some notion of its extent. " The scite of this manor-house being placed on the side slipp of a rising grownde, renders it to stand of that height, that betwixt the basis of the brick wall of the lower court, and the hall door of the sayd manor-house, there are five several ascents, consisting of three score and ten stepps, which are distinguished in a very graceful manner. The platforms were composed of Flanders brick, and the stepps of freestone, very well wrought. On the ground floor was a room called the stone gallery, 108 foot long, pillared and arched with gray marble." The ceiling of the hall " was of fret or parge work, in the middle whereof was fixed one well-wrought landskip, and round the same, in convenient distances, seven other pictures in frames, as ornaments to the whole roome ; the floor was of black and white marble."

449. As we have above observed, the Elizabethan style is a mixture of Gothic and Italian. It is characterised by orders very inaccurately and rudely profiled ; by arcades whose openings are often extravagantly wide, their height not unfrequently running up into the entablature. The columns on the piers are almost universally on pedestals, and are often banded in courses of circular or square blocks at intervals of their height ; when square, they are constantly decorated with prismatic raisings, in imitation of precious stones, a species of

ornament which is of very frequent recurrence. Nothing like unbroken entablatures appear; all is frittered away into small parts, especially in scrolls for the reception of inscriptions, which, at their extremities, are voluted and curled up, like so many pieces of scorched leather. All these eccentricities are so concentrated

Fig. 205.

QUEEN ELIZABETH'S MONUMENT.

in their sepulchral monuments, that no better insight into the leading principles of the style can be afforded than an example from Westminster Abbey, here given in the monument of Queen Elizabeth herself (*fig. 205.*). In this it will be seen that the taste is cumbrous and confused; and to add to the anomalies, the figures were coloured, and the different sorts of marbles and alabasters of numberless hues. The general composition consists in a large altar tomb under an open arcade, with a rich and complicated entablature. The columns are usually of black or white marble, of the Doric or Corinthian order. Small pyramidal figures, whose sides were richly veneered with variously coloured pieces, disposed in ornamented squares or circles supporting globes, are of continual occurrence. Armorial bearings in their various colours were introduced to excess. When the monument is placed against a wall, which is more usually the case, the plan was accommodated to it, and the alcove with its columns universally retained.

Among the best examples are those of Ratcliffe Earl of Surrey at Boreham, and of his countess in Westminster Abbey; of Dudley Earl of Leicester at Warwick, and of Carey Lord Hunsdon in Westminster Abbey.

450. It seems droll in this age, when throughout Europe the principles of good taste in architecture are so well understood, that fashion, induced by the cupidity and ignorance of upholsterers and decorators,—the curses of the art,—should again sanction an adoption of the barbarous forms and unmeaning puerilities which it might be supposed Jones and Wren had, by their example, consigned to a merited oblivion. We fear our warning voice will do little to suppress the rage till its cycle is completed. We have, in the prolongation of the subject, sacrificed our own feelings to the rage in the present day for designs of this class, and have assigned to it a far longer description than it deserves. The wretched cockney imitations of it perpetrated for retired shopkeepers in the insignificant villas of the suburbs of the metropolis, and occasionally for the amusement of country gentlemen a little more distant, as well as of what is called Gothic, appear to us in no other light than mockeries of a style which is repudiated by the manners of the nineteenth century. The style called Elizabethan we consider quite as unworthy of imitation as would be the adoption in the present day of the model of the ships of war, with their unwieldy and top-heavy poops, which encountered the Armada, in preference to the beautiful and compact form of a well-moulded modern frigate.

## SECT. VII.

JAMES I. TO ANNE.

451. The first of the reigns that heads this section has, in some measure, been anticipated in our notice of Elizabethan architecture, which it was impossible to keep altogether distinct

from the following reign. The angular and circular bay windows now disappeared entirely, and were supplanted by large square ones, of very large dimensions in their height, unequally divided by transoms, and placed in lengthened rows, so as to form leading features in the several stories of the building. Battlements were now entirely omitted, and the general effect of the pile became one of massive solidity, broken by a square turret loftier than those at the angles. The houses built in the reign of James I. are deficient in the picturesque beauty found in those of his predecessors. Many of them were finished by the architects named in the last section, and they were on a larger scale than even those of the age of Elizabeth. Audley Inn in 1616, Hatfield in 1611, and Charlton House in Wiltshire for Sir Henry Knevet, were, perhaps, the best specimens. The house at Campden, Gloucestershire, built by Sir Baptist Hicke, and which was burned down during the civil wars, consisted of four fronts, the principal one being towards the garden, upon the ground terrace; at each angle was a lateral projection of some feet, with spacious bay windows; in the centre a portico, with a series of the columns of the five orders (as in the schools at Oxford), and an open corridor. The parapet was finished with pediments of a capricious taste, and the chimneys were twisted pillars with Corinthian capitals. A very capacious dome issued from the roof, which was regularly illuminated for the direction of travellers during the night. This immense building was enriched with friezes and entablatures, most profusely sculptured; it is reported to have been erected at the expense of 29,000*l.*, and to have occupied, with its offices, a site of eight acres."

452. The use of the orders became more general. In Glamorganshire, at Beaupré Castle (1600), which has a front and porch of the Doric order, we find a composition including that just named, the Ionic and the Corinthian, wherein the capitals and columns are accurately designed and executed. The following table exhibits some of the principal houses of the period:—

House.	Date.	County.	Founder.	Present State.	Architect.
Holland House	1607	Middlesex	Sir Walter Cope	Perfect	John Thorpe
Bramshill	-	Hants	Edward Lord Zouche	do.	Uncertain.
Castle Ashby	-	Northampton	Herbert Lord Compton	do.	do.
Summer Hill	-	Kent	Earl of Clanricarde	do.	do.
Charlton	-	Wilts.	Sir Henry Knevet	Restored	do.
Hatfield	1611	Herts.	Robert Earl of Salisbury	Perfect	do.
Longford Castle	1612	Wilts.	Sir T. Gorges	do.	John Thorpe.
Temple Newsham	-	Yorkshire	Sir Arthur Ingram	do.	Uncertain.
Charlton	-	Kent	Sir Adam Newton	do.	do.
Bolsover	1613	Derby	Sir Charles Cavendish	{ Dilapidated	{ Huntingdon and Smithson.
Audley Inn	1616	Essex	T. Earl of Suffolk	Perfect	B. Jansen.
Wollaton	-	Notts.	Sir Francis Willoughby	do.	{ J. Thorpe and Smithson.

453. Under James, the pride and magnificence of the aristocracy was as equally displayed in the sumptuous monuments erected to the memory of the departed as in their stately palaces; and we can scarcely point to a county in England whose parish churches do not attest the fact by the gorgeous tombs that exist in villages where the mansions of those thus commemorated have not long since passed from the memory of man. A year's rental of an estate, and that frequently under testamentary direction, was often squandered in the sepulchral monument of the deceased lord of a manor.

454. In the reign of James I. properly commences the career of Inigo Jones, to which we hasten with delight, as indicating the dawn of true architecture (for the Gothic had irretrievably passed away) in England. It resembles the arrival of a traveller at an oasis in the desert, after a parching and toilsome journey. "Jones, if a table of fame," says Walpole, "like that in the Tatler, were to be formed for men of real and indisputable genius in every country, would save England from the disgrace of not having her representative among the arts. She adopted Holbein and Vandyck, she borrowed Rubens, she produced Inigo Jones. Vitruvius drew up his grammar, Palladio showed him the practice, Rome displayed a theatre worthy his emulation, and King Charles was ready to encourage, employ, and reward his talents. This is the history of Inigo Jones as a genius." Generally speaking, we are not admirers of Walpole, who often sacrificed truth to fancy, and the character of an artist to a prettily-turned period; hence we are disinclined to concur in his criticisms without many qualifications; but in this case he has so well expressed our own

feelings, that we regret we cannot add force to the observations in which we so fully concur.

455. Inigo Jones was the son of a clothworker, and was born about 1572. From the most probable accounts he appears to have been apprenticed to a joiner, in which state he was, from some accounts, discovered by the Earl of Arundel, from others by William Earl of Pembroke, and by one or other of these noblemen sent to Italy, rather, however, according to Walpole, to study the art of painting, than that of architecture, for the former of which, the author named says, Nature appears not to have fitted him, inasmuch as "he dropped the pencil, and conceived Whitehall." But our own belief is, that though he might have afterwards been patronised by both the noblemen above mentioned, he owed this part of his education to neither of them; for, considering that at his first visit to Italy, before 1605, Lord Pembroke was but just of age, and that Lord Arundel was somewhat younger, there is no great probability that either of them thus assisted him in his studies on the Continent.

456. Of his employment as an architect nothing can be traced previous to the visit of James I. to the University of Oxford, in 1605, at which time he was thirty-three years old; and then, according to Leland (*Collectanea*, App. vol. vi. p. 647.), "They" (the University) "hired one Mr. Jones, a great traveller, who undertook to further them with rare devices, but performed little to what was expected. He had for his pains, I have constantly heard, 50*l.*;" from which it is certain that his earliest visit to Italy was before 1605. At Venice he became acquainted with the works of Palladio; and there, as Walpole observes, "learned how beautifully taste may be exerted on a less theatre than the capital of an empire." In this city his reputation was so great, that Christian IV. appointed him his architect, though of the buildings erected by him in Denmark we know nothing. In this country's capital, however, he was found by James, and by his Queen (Anne) was removed from Copenhagen to Scotland, in the quality of her architect. By Prince Henry he was employed in the same capacity, and about this time had the grant in reversion of surveyor general of the works. On the untimely and lamented death of that prince, he once more visited Italy, where he perfected his taste and ripened his judgment. It appears more than probable that it was previous to his second journey that he designed those of his buildings that partake of a bastard style. These buildings, however, are such as could, under the circumstances, have been designed only by a great master in a state of transition from one style to another; such, for instance, are the north and south sides of the quadrangle at St. John's College, Oxford, in which he seems to have copied all the faults of the worst examples of his great master Palladio; still the composition is so picturesque, that, though reluctantly, we cannot avoid admiring it. In the garden front of

Fig. 206.

GARDEN FRONT OF ST. JOHN'S.

the same college (*fig.* 206.), notwithstanding its impurity, there is a breadth and grandeur which subdue criticism, and raise our admiration; and we by no means subscribe to Horace Walpole's dictum, that "Inigo's designs of that period have a littleness of parts and a weight of ornament." Previous to his second return to England, the surveyor's place had fallen in, and finding the office in debt, he prevailed, as Walpole observes, with an air of

Roman disinterestedness, and showing that architecture was not the only thing he had learned in Rome, on the comptroller and paymaster of the office, to give up, as he did, all the profits of the office till the arrears were cleared.

457. By the *Fædera*, vol. xviii. p. 99., we find that there was issued to him, in conjunction with the Earl of Arundel and others, a commission to prevent the building on new foundations within two miles of London and the palace of Westminster; and in 1620 he was, if possible, more uselessly employed by James I. in guessing, for it was no more, who were the builders of Stonehenge. For this last, the necessary preliminary information had not even dawned, although Walpole, in his usual off-hand manner, loses not, in alluding to it, the opportunity of displaying his own dreadful ignorance on the subject. (See Chap. II. Sect. II., where this monument has been examined.) In the year last named, Jones was one of the commissioners for the repair of old St. Paul's, though the repairs were not commenced till 1633, in which year Laud, then Bishop of London, laid the first stone, and Inigo Jones the fourth. Our architect was now too much disinclined to Gothic to bend his genius to

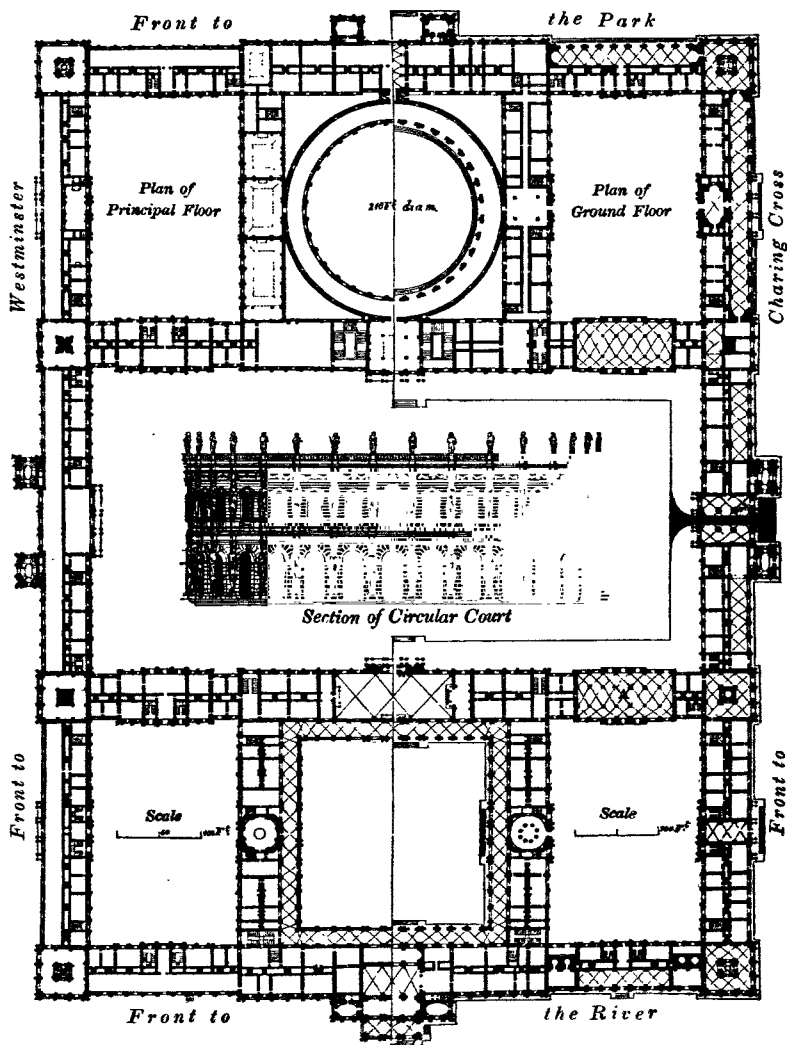

Fig. 207.

PLAN OF WHITEHALL.

anything in the shape of a restoration; and though the Roman portico which he placed before the church was magnificent, the application of Roman to Gothic architecture of course ruined the cathedral. The reader will find a representation of this portico in Dugdale's *St. Paul's*. Abstractedly considered, it was a fine composition; and its dimensions, of a length of 200 ft., a depth of 50 ft., and a height of 40 ft., were calculated to give it an imposing effect.

458. The Banqueting House at Whitehall, which we have pride in quoting as one of the most magnificent works in Europe, has generally been supposed to have been erected in the reign of Charles I.; but there is sufficient reason for assigning the period of its execution to the preceding reign. It was begun in 1619, and finished in two years. The designs for the palace of Whitehall, whereof *fig. 207.* at the foot of the preceding page, exhibits a block plan, on which the banqueting-house (at A), it will be seen, forms a very inconsiderable portion, would, had they been executed, have formed, beyond all comparison, the finest in the world. In magnitude it would have exceeded even the palace of Diocletian. The form, as will be observed, was an oblong square, and consisted of seven courts, whereof six were quadrangular. The central one was larger than the other two chief divisions; and these were again subdivided into three courts, the centre one of which, on the north side, had two galleries with arcades, and that on the south a circular Persian court, as it was called, whose diameter was 210 ft. Surrounded on the ground floor by an open arcade, the piers between the arches were decorated with figures of Persians, with what propriety it is useless to discuss; and the upper story was ornamented between each window with caryatides, bearing Corinthian capitals on their heads, surmounted by an entablature of that order, and the whole was finished by a balustrade. Towards Westminster, the front extended 1152 ft.; and that towards the park, in which the length of the banqueting-house is included, would have been 720 ft. With the exception of Westminster Hall, the banqueting-house (now used as a chapel) is the largest room in England, its length being 115 ft., breadth 60 ft., and height 55 ft.

459. In 1623, Jones was employed on Somerset House, to the garden front whereof he executed (*fig. 208.*) a façade of singular beauty, lost to the world by its demolition on the

Fig. 208.

WATER FRONT OF OLD SOMERSET HOUSE.

rebuilding of the edifice for its present purposes. On the ascent of Charles I. to the throne, our architect seems to have been very much employed. As surveyor of the public buildings, his stipend was 8s. 4d. a day, besides an allowance of 46*l.* per annum for house-rent, a clerk, and incidental expenses.

460. In the passion for masques which prevailed during the reign of Charles I., Jones was a principal contributor to their splendour. They had been introduced into this country by Anne of Denmark; and Walpole gives a list of thirteen to which he furnished the scenes and machinery.

461. Those that have seen Wilton can appreciate Inigo's merit for having introduced into England, in the seats of our aristocracy, a style vying with that of the villas of Italy. Some disagreement appears to have arisen between him and Philip Earl of Pembroke, which here it would be irrelevant to dwell on; we will merely mention that in the Harleian library existed an edition of Jones's *Stonehenge*, which had formerly belonged to the nobleman in question; and that its margins are filled by the former

possessor with notes, not on the substance of the work itself, but on its author, and anything else that could be injurious. He calls him "Iniquity Jones," and says he had 16,000*l.* a year for keeping the king's houses in repair. The censures were undeserved; and the accusations, unwarranted by facts, are extremely discreditable to the memory of Earl Philip.

Fig. 209.

YORK STAIRS.

462. The works of Jones were exceedingly numerous; many, however, are assigned to him which were the productions of his scholars. Such buildings as the Queen's house at Greenwich (much altered, and, indeed, spoiled, of late years, for the purpose of turning it into a public naval school); Coleshill, in Berkshire, built in 1650; Shaftesbury House, in Aldersgate Street; the square, as planned, and Church of St. Paul, Covent Garden; and many other works, are strong proofs of the advancement of architecture during his career. York Stairs (*fig. 209.*), another of his examples, exhibits a pureness and propriety of character which appears to have been afterwards unappreciated by his successors, with Wren at their head, whose mention by

the side of Jones is only justified by the scientific and constructive skill he possessed.

463. Jones was a follower of the Venetian school, which we have described in a previous section. His respect for Palladio is evinced by the circumstance of a copy of that great master's works being his companion on his travels through Italy. It is filled with his autograph notes, and is now deposited in the library of Worcester College, Oxford. Lord Burlington had a Vitruvius noted by him in a similar manner. It is curious to see the amateurs and pseudo-critics of the present day decry these two authors, whom Jones, a genius of the first order, thought his best instructors. The class in question are, however, no longer considered worthy of being listened to on matters of the art; and the public taste is, in this respect, turning once more into the proper channel. Palladian architecture, thus introduced by Jones, would have reached a splendour under Charles I. perhaps equal to that which Italy can boast, had not its progress been checked by public calamities, in which it was the lot of the artist to share the misfortunes of his royal master. In addition to being the favourite of the king, he was a Roman Catholic; and for this (as it was then curiously called) delinquency, he had to pay 54*l.* in the year 1646. Grief, misfortunes, and a consequent premature old age, terminated the life of this great man at Somerset House on the 21st of July, 1651.

464. The plans of houses introduced from Italy by this master were not, perhaps, altogether suited to the climate or habits of the English. One of his greatest faults was that of aiming at magnificence under circumstances in which it could not be attained. Thus, his rooms were often sacrificed to the show and effect resulting from a hall or a staircase, or both; sometimes, to gain the appearance of a vista of apartments, they were made too small for the scale of the house. His distribution of windows is purely Italian, and the piers between them consequently too large, so that the light is occasionally insufficient in quantity. The habits of Italy, which enabled Palladio to raise his principal floor, and to have the farm offices and those for the vintage in the same range of building as the mansion, impart an air of great magnificence to the Italian villa. Jones saw that this arrangement was not required for English convenience, and therefore avoided the Palladian practice; "but," says Mitford, "the architects who followed him were dazzled, or dazzled their employers. To tack the wings to the centre with a colonnade became a phrase to express the purpose of plan of the most elegant effect; and the effect, provided the combination be harmonious, will be elegant; but the arrangement is very adverse to general convenience, and especially in the moderate scale of most general use. Where great splendour is the object, convenience must yield to it. Magnificence must be paid for in convenience as well as money." Webb and Carter were the pupils of Jones. The former will furnish us presently with a few remarks. During the time of the Commonwealth, the history of architecture in this country is a complete blank. We know of no public work of consequence that was designed or executed in the interregnum. On the restoration of

the monarchy, however, the art began to revive; but it was much tinged with the contemporary French style, which Lord Burlington, on its reappearance many years afterwards, had the merit of reforming, and of bringing back the public taste to the purity which Jones had introduced: but this we shall have to notice hereafter.

465. John Webb was nephew as well as scholar of Inigo Jones, whose only daughter he married. He built a large seat for the Bromley family at Horseheath, in Cambridgeshire; and added a portico to the Vine, in Hampshire, for Challoner Chute, the Speaker to Richard Cromwell's parliament. Ambresbury, in Wiltshire (*fig. 210.*), was only executed

Fig. 210.

AMBRESBURY.

by him from the designs of his master, as also the east side of the court of Greenwich Hospital. Captain William Winde, a native of Bergen-op-Zoom, and pupil to Sir Balthazar Gerbier, was, soon after the Restoration, in considerable employ as an architect. He built Cliefden House, Bucks, which was destroyed by fire in 1795; the Duke of Newcastle's, in Lincoln's Inn Fields; Combe Abbey, Warwickshire, for Lord Craven; and for the same peer he finished Hempsted Marshall, which had been begun by his master. But the chief and best work of Winde was Buckingham House, in St. James's Park, on whose site now stands a palace, larger, indeed, but unworthy to be its successor. It is known from prints, and not a few of our readers will probably recollect the building itself. It was erected for John Sheffield, Duke of Buckingham; and on its frieze was the inscription "sic srrr LÆTANTUR LARES." The arrears in the payments for this house, according to an anecdote in Walpole, were so distressing, that when it was nearly finished, "Winde had enticed his Grace to mount upon the leads to enjoy the grand prospect. When there, he coolly locked the trap-door, and threw the key to the ground, addressing his astonished patron, 'I am a ruined man, and unless I have your word of honour that the debts shall be paid, I will instantly throw myself over.' 'And what is to become of me,' said the duke? 'You shall come along with me.' The promise was given, and the trap-door opened (upon a sign made) by a workman in the secret, and who was a party to the plot." We do not vouch for the truth of the tale.

466. An architect of the name of Marsh is said, by Vertue, to have designed the additional buildings at Bolsover, as also to have done some considerable works at Nottingham Castle; and Salmon, in his account of Essex, mentions a Doctor Morecroft, who died in 1677, as the architect of the manor-house of Fitzwalters. Of the works of the French taste about the middle of the period under discussion, a better notion cannot be obtained than from Montague House, now the British Museum (*fig. 211.*), the work of a Frenchman here whose example had followers; indeed, Wren himself, in some of his works, has caught the vices of the French school of the day, though he was a follower of the Venetian and Roman schools. The fire which destroyed London in 1666, a few years after the death of Jones, brought into notice the talents of Sir Christopher Wren, whose career was opened under

Fig. 211.

BRITISH MUSEUM.

the reign of Charles II. "The length of his life enriched the reigns of several princes and disgraced the last of them." (At the advanced age of 86 he was removed by George I. from the office of Surveyor General.) "A variety of knowledge proclaims the universality, a multiplicity of works the abundance, St. Paul's the greatness, of Sir Christopher's genius. The noblest temple, the largest palace, the most stupendous hospital, in such a kingdom as Britain, are all works of the same hand. He restored London and recorded its fall." As the boast of England is the Cathedral Church of St. Paul, it will be necessary to dwell a little on a description of it.

467. The larger portion of this cathedral stands on part of the site of the old one, as shown by the annexed diagram (Fig. 212.), which also exhibits their comparative sizes. It is

Fig. 212.

PLAN OF OLD AND NEW ST. PAUL'S.

copied from a drawing by Sir Christopher in the library of All Souls College at Oxford. The instructions to the surveyor, according to the compiler of the Parentalia, were—"to contrive a fabric of moderate bulk, but of good proportion; a convenient quire, with a vestibule and porticoes, and a dome conspicuous above the houses;" and in conformity with them, a design was made which, from various causes, does not appear to have given satisfaction; whereon the compiler observes, that "he endeavoured to gratify the taste of the connoisseurs and criticks with something coloss and beautiful, with a design antique and well studied, conformable to the best style of the Greek and Roman architecture." The model made from this design is still preserved in the cathedral. This however was, unfortunately, not approved, and, as our informant continues, "the surveyor then turned his thoughts to a cathedral form, so altered as to reconcile as near as possible the Gothic to a better manner of architecture." These last designs were approved by Charles, who issued his warrant under privy seal on the 1st of May, 1675, for the execution of the works.

468. Much trouble was experienced in removing the immense ruins of the old church, for the destruction whereof recourse was had to many expedients. On the north side, the foundations are placed upon a stratum of hard pot earth about 6 ft. in thickness, but not more

than 4 ft. thick on the south side; and upon this stratum, from the experience of the old church having firmly rested, the architect wisely determined to place the new one. The work was commenced on the western side, driving eastward to the extremity of the site; at which, on the northern side, a pit was discovered whence the hard pot earth had been extracted, and the vacuity so made filled up with loose rubbish. The length of this hole in the direction of the foundation was not more than 6 or 7 ft., and from the fear of piles, if driven, becoming rotten, the surveyor determined to excavate through the sand, and to build up from the stratum solid for a depth of 40 ft. The pit sunk here was 18 ft. wide; in this he built up a pier, 10 ft. square, till it rose to within 15 ft. of the present surface. At this level he introduced an arch from the pier to the main foundation, and on this arch the north-eastern quoin of the choir is founded.

469. On the 21st of June, 1675, the first stone was laid; and, within ten years, the walls of the choir and its side aisles, and the north and south circular porticoes, were finished; the piers of the dome also were brought up to the same height. The son of the architect laid the last stone in 1710. This was the highest stone on the top of the lantern. Thus the whole edifice was finished in thirty-five years, under the remarkable circumstances of having only one architect, one master mason (Mr. Strong), and the see being occupied the whole time by one bishop; Doctor Henry Compton.

470. The plan of St. Paul's is a Latin cross, and bears a general resemblance to that of St. Peter's. A rectangular parallelogram, 480 ft. from east to west (measuring from the top of the steps of the western portico to the exterior of the eastern wall of the choir), is crossed by another parallelogram, whose extremities form the transepts, 250 ft. in length from north to south. At the eastern end of the first parallelogram is a hemicylindrical recess, containing the altar, and extending 20 ft. further eastward; so that the whole length is 500 ft., exclusive of the flight of steps. At the north and south ends of the transepts are porticoes, segmental on the plan, and projecting 20 ft. The centre of the intersection of the parallelograms is 280 ft. from the western front. The width of each parallelogram is 125 ft. At the western end of the edifice, on the north and south extremities, are towers whose western faces are in the same plane as the general front, but whose northern and southern faces respectively project about 27 ft. from the walls of the aisles of the nave; so that the whole width of the western front is about 180 ft. In the re-entering angles on each side, between the towers and the main building, are two chapels, each 50 ft. long and 20 ft. broad, open to the aisles of the nave at their western end. Externally two orders reign round the building. The lower one Corinthian, standing on a basement 10 ft. above the level of the ground, on the western side, where a flight of steps extending the whole breadth of the front, exclusive of the towers, leads to the level of the church. The height of this order, including the entablature, is 50 ft.; and that of the second order, which is composite, is one fifth less, or 40 ft.; making the total height 100 ft. from the ground to the top of the second entablature. The portico of the western front is formed with the two orders above mentioned, the lower story consisting of twelve coupled columns, and the upper one of eight; which last is surmounted by a pediment, whose tympanum is sculptured with the subject of the Conversion of St. Paul, in pretty high relief. Half of the western elevation, and the half transverse section, is given in *fig.* 213. At the northern and southern ends of the transepts the lower order is continued into porticoes of six fluted columns, standing, in plan, on the segment of a circle, and crowned with a semi-dome abutting against the ends of the transepts.

471. The porch of the western front is 50 ft. long and 20 ft. wide: the great doorway, being in the centre of it, leads to a vestibule 50 ft. square, at whose angles are four piers connected at top by semicircular arches, under which are placed detached coupled columns in front of the piers. The body of the church is divided into a nave and two side aisles, decorated with pilasters supporting semicircular arches; and on each side of the porch and vestibule is a passage which leads directly to the corresponding aisles. The choir is similarly disposed, with its central division and side aisles.

472. The entrances from the transepts lead into vestibules 25 ft. deep, and the whole breadth of the transept in length, each communicating with the centre by a central passage and its aisles formed between two massive piers and the walls at the intersections of the transepts with the choir and nave. The eight piers are joined by arches springing from one to the other so as to form an octagon at their springing points, and the angles between the arches, instead of rising vertically, *sail* over as they rise and form *pendentives*, which lead, at their top, into a circle on the plan. Above this a wall rises in the form of a truncated cone, which, at the height of 168 ft. from the pavement, terminates in a horizontal cornice, from which the interior dome springs. Its diameter is 100 ft., and it is 60 ft. in height, in the form of a paraboloid. Its thickness is 18 in., and it is constructed of brickwork. From the haunches of this dome, 200 ft. above the pavement of the church, another cone of brickwork commences, 85 ft. high, and 94 ft. diameter at the bottom. This cone is pierced with apertures, as well for the purpose of diminishing its weight as for distributing light between it and the outer dome. At the top it is gathered into a dome, in the

Fig. 213. HALF ELEVATION AND HALF SECTION OF ST. PAUL'S.

form of a hyperboloid, pierced near the vertex with an aperture 12 ft. in diameter. The top of this cone is 285 ft. from the pavement, and carries a lantern 55 ft. high, terminating in a dome, whereon a ball and cross is raised. The last-named cone is provided with corbels, sufficient in number to receive the hammer beams of the external dome, which is of oak, and its base 220 ft. from the pavement, its summit being level with the top of the cone. In form, it is nearly hemispherical, and generated by radii 57 ft. in length, whose centres are in a horizontal diameter, passing through its base. The cone and the interior dome are restrained in their lateral thrust on the supports by four tiers of strong iron chains, placed in grooves prepared for their reception, and run with lead. The lowest of these is inserted in the masonry round their common base, and the other three at different heights on the exterior of the cone. Externally the intervals of the columns and pilasters are occupied by windows and niches, with horizontal and semicircular heads, and crowned with pediments. In the lower order, excepting modillions under the corona, the entablature is quite plain, and there are also console modillions in the upper order. The edifice, in three directions, is terminated with pediment roofs; and at the extremities, on each of those faces, are acroteria, supporting statues 25 ft. above the roof of the edifice. Over the intersection of the nave and transepts for the external work, and for a height of 25 ft. above the roof of the church, a cylindrical wall rises, whose diameter is 146 ft. Between it and the lower conical wall is a space, but at intervals they are connected by cross walls. This cylinder is quite plain, but perforated by two courses of rectangular apertures. On it stands a peristyle of thirty columns of the Corinthian order, 40 ft. high, including bases and capitals, with a plain entablature crowned by a balustrade. In this peristyle, every fourth intercolumniation is filled up solid, with a niche, and connection is provided between it and the wall of the lower cone. Vertically over the base of that cone, above the peristyle, rises another cylindrical wall, appearing above the balustrade. It is ornamented with pilasters, between which are a tier of rectangular windows above, and one of blanks below. On this wall the external dome is posited. As will be seen by reference to the section, the lantern which we have before noticed receives no support from it. It is merely ornamental, differing entirely in that respect from the dome of St. Peter's.

473. The towers in the western front are 220 ft. high, terminating in open lanterns, covered with domes formed by curves of contrary flexure, and not very purely composed, though perhaps in character with the general façade.

474. The interior of the nave and choir are each designed with three arches longitudinally springing from piers, strengthened, as well as decorated, on their inner faces, by an entablature, whose cornice reigns throughout the nave and church. Above this entablature, and breaking with it over each pilaster, is a tall attic from projections, on which spring semicircular arches which are formed into *arcs doubleaux*. Between the last pendentives are formed, terminated by horizontal cornices. Small cupolas, of less height than their semi-diameter, are formed above these cornices. In the upright plane space on the walls above the main arches of the nave, choir, and transepts, a *clerestory* is obtained over the Attic order, whose form is generated by the rising of the pendentives. The inner dome is plastered on the under side, and painted by Sir James Thornhill, with subjects relating to the history of St. Paul.

475. For external elegance, we know no church in Europe which exhibits a cupola comparable with that of St. Paul's, though in its connection with the church by an order higher than that below it there is a violation of the laws of the art. The cost of the church was 736,752*l.*, exclusive of the stone and iron enclosures round it, which cost 11,202*l.* more; in all 747,954*l.* About nine-tenths of that sum were raised by a tax on coals imported into London. As compared with St. Peter's, we subjoin a few of the principal dimensions of the two churches.

Direction of Measure.	St. Peter's in English Feet.	St. Paul's in English Feet.	Excess of the former in Feet.
Length within - -	669	500	169
Breadth at entrance - -	226	100	126
Principal façade - -	395	180	215
Breadth at the cross - -	442	223	219
Cupola, clear diameter - -	139	108	31
Cupola, height of, with lantern - -	492	330	162
Church in height - -	146	110	36

476. If we suppose sections to be made through the transepts of the four principal churches of Europe, we have their relative sizes in the following ratio : —

St. Peter's, Rome - - - -	-	-	-	1·0000
Santa Maria del Fiore, at Florence - - - -	-	-	-	·5358
St. Paul's, London - - - -	-	-	-	·4166
St. Genevieve (Pantheon), Paris - - - -	-	-	-	·3303

477. Notwithstanding its imposing effect as a whole, and the exhibition in its construction of a mechanical skill of the very highest order; notwithstanding, also, the abstract beauty of the greater number of its parts, it is our duty to observe that many egregious abuses are displayed in the fabric of St. Paul's, the first and greatest whereof is the great waste of interior effect as compared with the total section employed. If we suppose, as before, sections from north to south to be made through the transepts of the four principal churches, the following table will exhibit the proportion of their clear internal to their external areas : —

St. Peter's, Rome - - - -	-	-	-	-	8,325 : 10,000
Santa Maria del Fiore, Florence - - - -	-	-	-	-	8,855 : 10,000
St. Paul's, London - - - -	-	-	-	-	6,865 : 10,000
St. Genevieve (Pantheon), Paris - - - -	-	-	-	-	6,746 : 10,000

Whence it is seen how highly in this respect the Duomo of Florence ranks above the others. The defect of St. Paul's in this respect is mainly induced by the false dome; and though we may admire the ingenuity that provided for carrying a stone lantern on the top of a truncated cone, deceitfully appearing, as it does, to stand on the dome from which it rises, we cannot help regretting that it afforded the opportunity of giving the building a cupola, liable to the early attack of time, and perhaps that, more to be dreaded, of fire.

478. In the skill required for raising a building on a minimum of foundation, Sir Christopher Wren appears to have surpassed, at least, those who preceded him. In similarly or nearly so formed buildings, some criterion of the comparative skill employed in their construction may be drawn from comparing the ratio between the area of the whole plan, and that of the sum of the areas of the horizontal sections of the whole of the piers, walls, and pillars, which serve to support the superincumbent mass. The similarity of the four churches already compared affords, therefore, a criterion of their respective merits in this respect. We hardly need say that one of the first qualifications of an architect is to produce the greatest effect by the smallest means. The subjoined table is placed before the reader as a comparison of the four churches in reference to the point in question.

Church.	Whole Area in English Feet.	Area of Points of Support.	Ratio.
St. Peter's at Rome - -	227,069	59,308	1 : 0·261
Sta. Maria del Fiore, Florence	84,802	17,030	1 : 0·201
St. Paul's, London - -	84,025	14,311	1 : 0·170
St. Genevieve (Pantheon), Paris	60,287	9,269	1 : 0·154

The merit, therefore, shown in the *construction* of the above edifices will be nearly as 15, 17, 20, 26, or inversely proportional to the numbers in the last column.

479. We must here mention one of the most unpardonable defects, or rather abuses, which this church exhibits, and which must be learnt from reference to *fig. 214*. Therein is

Fig. 214.

ST. PAUL'S. SECTION WITH BUTTRESSES.

given a transverse section of the nave and its side aisles. From this it will be seen that the enormous expense of the second or upper order all round the church was incurred for no other purpose than that of concealing the flying buttresses that are used to counteract the thrusts of the vaults of the nave, choir, and transepts, — an abuse that admits of no apology. It is an architectural fraud. We do not think it necessary to descend into minor defects and abuses, such as vaulting the church from an Attic order, the multiplicity of breaks, and want of repose; the general disappearance of tie and connection, the piercing, as practised, the piers of the cupola, and mitring the archivolts of its great arches, and the like, because we think all these are more than counterbalanced by the beauties of the edifice. We cannot, however, leave the subject without observing that not the least of its merits is its freedom from any material settlement tending to bring on premature dilapidation. Its chief failures are over the easternmost arch of the nave, and in the north transept, for the remedy whereof (the latter) the architect left written instructions. There are also some unimportant failures in the haunches of most of the flying buttresses, which are scarcely worth notice.

480. The wretchedly naked appearance of the interior of this cathedral is a disgrace neither to the architect nor to the country, but to the clergy, Terrick, bishop of London, and Potter, archbishop of Canterbury, who refused to sanction its decoration with pictures, gratuitously proffered by artists of the highest reputation; and this after the cupola itself had been decorated. The colour of the sculpture is of no use in heightening the effect of the interior.

481. The *Parentalia* contains a description of the manner in which the walls of the old

cathedral were destroyed, and those of the present one raised; which should be read by all those engaged in the practice of architecture.

482. Wren, having lived to see the completion of St. Paul's, died in 1723, at the age of 91, and was buried under the fabric, "with four words," says Walpole, "that comprehended his merit and his fame.

"SI QUÆRAS MONUMENTUM CIRCUMSPICE."

483. It will be impossible, consistently with our space, to describe the works of Sir Christopher Wren. One upon which his fame is as justly founded as upon St. Paul's itself, is St. Stephen's Church in Wallbrook, in which, on a plot of ground  $80\frac{1}{2}$  ft. by  $59\frac{1}{2}$  ft., he has contrived a structure whose elegance is not surpassed by any one we know to have been raised under similar restrictions. The church in question is divided longitudinally into five aisles by four ranks of Corinthian columns standing on pedestals; the places of four columns near the centre being unoccupied; the surrounding central columns form the angles of an octagon, 45 ft. diameter, on which arches are turned, and above which, by means of pendentives, the circular base of a dome is formed, which is in the shape of a segment of a sphere, with a lantern thereon. The ceiling of the middle aisle from east to west is vaulted in groins. The rest of the ceiling is horizontal. The interior of St. James's, Westminster, is another beautiful example of the master, though recently underrated by an ignorant critic.

484. One of the peculiarities remarkable about Wren's period is the investment of the form of the Gothic spire with a clothing of Italian architecture, by which the modern steeple was produced. If any example could reconcile us to such a practice, it might be found in that of Bow Church, another of Wren's works, which rises to the height of 197 ft. from the ground, the sides of the square from which it rises being 32 ft. 6 in. There are, in the leading proportions of this tower and spire, some extraordinary examples in relative heights as compared with widths sesquilaterally, which would almost lead one to suppose that, in this respect, our architect was somewhat superstitious.

485. In St. Dunstan in the East, Wren attempted Gothic, and it is the least offensive of his productions in that style. It is an elegant composition, but wants the claim to originality. St. Nicholas, Newcastle, and the High Church, Edinburgh, are its prototypes.

486. The Monument of London is original, notwithstanding columns of this sort had been previously erected. Its total expense was 8856*l.*, and it was commenced in 1671, completed in 1677. The height is 202 ft.; hence it is loftier than any of the historical columns of the ancients. The pedestal is about 21 ft. square, standing on a plinth 6 ft. wider. The lower diameter of the column on the upper part of the base is 15 ft., and the shaft incloses a staircase of black marble, consisting of 345 steps. It was fluted after the work was carried up. The quantity of Portland stone whereof it is composed is 28,196 cubic feet. The Antonine column at Rome is 175, and that of Trajan 147 ft. high. That erected by Arcadius at Constantinople, when perfect, was of the same height as that last mentioned. The structure of which we are speaking loses much by its situation, which has neither been improved nor deteriorated by the streets consequent on the rebuilding of London Bridge: and though it cannot compete with the Trajan column in point of intrinsic beauty, it is, nevertheless, an exquisite and well-proportioned work, and seems much better calculated with propriety to record the object of its erection, than the other is to be the monument of a hero. In these days, it is singular to see that no other mode than the erection of a column could be found to record the glorious actions of a Nelson. Such was the poverty of taste that marked the decision of the committee to whom that object was most improperly entrusted.

487. Among the works of Wren not to be passed without notice is the Library of Trinity College, Cambridge. It is one of his finest productions, and one with which he himself was well satisfied. It consists of two orders; a Doric arcade below, open to a basement supported by columns, which has a flat ceiling, exceedingly convenient as an ambulatory, and itself simple and well proportioned. The principal story is decorated with three-quarter columns of the Ionic order, well proportioned. From their volutes, festoons are pendent, and the key-stones of the windows are carved into cherubs' heads, &c. This is the elevation towards Nevill's Court; that towards the garden has three Doric doors below, but above is without columns or pilasters in the upper stories. Without ornament, it is not the less graceful and imposing. The interior, as a single room, is designed with great grandeur and propriety.

488. We cannot further in detail continue an account of the works of this extraordinary architect, but shall now proceed to submit a list of his principal works, together with a catalogue of those of his principal churches whose estimates exceeded the cost of 5000*l.*

489. We must here close our account of Wren. Those of our readers who desire further information on the life and works of this truly great man will do well to consult the *Parentalia, or Memoirs of the Family of the Wrens*, compiled by his son, and published by his grandson Stephen Wren. Fol. Lond. 1750.

490. Among the architects of Wren's time, there was a triad of amateurs who would have done honour to any nation as professors of the art. The first of these was Henry Aldrich, D.D., Dean of Christ Church, Oxford, who died in 1710. He was attached to the Venetian school, as we may see in the three sides of Peckwater quadrangle, and the garden front of Corpus Christi College, a façade which for correct taste is not surpassed by any edifice in Oxford. The second of these amateurs was Dr. Clarke, one of the Lords of the Admiralty in the reign of Queen Anne. This distinguished amateur sat for Oxford in fifteen sessions. The Library of Worcester College, to which he bequeathed his valuable architectural collection of books and MSS., was from his design. He built the library at Christ Church. The third was Sir James Burrough, Master of Caius College, Cambridge; by whom, in 1703, the chapel of Clare Hall in that University was beautifully designed and executed.

491. We now approach the works of a man who, whatever some have thought of them, has a stronger claim on our notice as an inventor than any of his predecessors. It must be anticipated that we allude to Sir John Vanbrugh. Upon no other artist has Walpole delivered criticisms more unworthy of himself, nor is there any one of whose genius he had less capacity to appreciate the powers. The singular mind of Vanbrugh was distracted by control: his buildings are the result of a combination of forms and anticipation of effects, originating solely from himself; effects which none before had seen nor

contemplated. As a wit, he was inferior to none that levelled its shafts at him, and hence his novel compositions in architecture became among the professed critics of the day so much the more an object of derision, as, in their puny notions, his only assailable point. Attacked from party feeling, the public allowed itself to be biassed by epigrams and smart verses from the pens of Pope and Swift; and when the former, in his fourth epistle, in allusion to Vanbrugh's works, exclaims, —

“ Lo ! what huge heaps of littleness around,  
The whole a laboured quarry above ground,” —

he little thought he was leaving to posterity a record of his consummate ignorance of art, and of his total insensibility to grandeur, in all that relates to composition in architecture.

492. The opinion of Sir Joshua Reynolds first enlightened the public upon the thitherto condemned works of this extraordinary architect. “ I pretend,” says Reynolds, in his fifth discourse, “ to no skill in architecture. I judge now of the art merely as a painter. When I speak of Vanbrugh, I speak of him merely on our art. To speak, then, of Vanbrugh in the language of a painter, he had originality of invention, he understood light and shadow, and had great skill in composition. To support his principal object, he produced his second and third groups of masses; he perfectly understood in *his* art what is most difficult in ours, the conduct of the backgrounds by which the design and invention is (are) set off to the greatest advantage. What the background is in painting is the real ground upon which the building is erected; and as no architect took greater care that his work should not appear crude and hard, — that is, that it did not abruptly start out of the ground, without expectation or preparation, — this is the tribute which a painter owes to an architect who composes like a painter.” The testimony of Mr. Payne Knight, a person of a taste highly refined and cultivated, in his *Principles of Taste*, is another eulogium on the works of this master. And again we have the concurrence therein of another able writer on these subjects, who, though frequently at variance in opinion with Mr. Knight, thus expresses himself in his *Essay on the Picturesque*, vol. ii. p. 211. : “ Sir J. Reynolds is, I believe, the first who has done justice to the architecture of Vanbrugh, by showing it was not a mere fantastic style, without any other object than that of singularity, but that he worked on the principles of painting, and that he has produced the most painter-like effects. It is very probable that the ridicule thrown on Vanbrugh's buildings, by some of the wittiest men of the age he lived in, may have in no slight degree prevented his excellencies from being attended to; for what has been the subject of ridicule will seldom become the object of study or imitation. It appears to me, that at Blenheim, Vanbrugh conceived and executed a very bold and difficult design, that of uniting in one building the beauty and magnificence of the Grecian architecture, the picturesqueness of the Gothic, and the massive grandeur of a castle; and that, in spite of many faults, for which he was very justly reproached, he has formed, in a style truly his own, and a well-combined whole, a mansion worthy of a great prince and warrior. “ His first point appears to have been massiveness, as the foundation of grandeur: then, to prevent the mass from being a lump, he has made

Fig. 215.

PLAN OF BLENHEIM.

various bold projections of various heights, which seem as foregrounds to the main building; and, lastly, having been probably struck with a variety of outline against the sky in many Gothic and other ancient buildings, he has raised on the top of that part where the slanting roof begins in any house of the Italian style, a number of decorations of various characters. These, if not new in themselves, have, at least, been applied and combined by him in a new and peculiar manner, and the union of them gives a surprising splendour and magnificence, as well as variety, to the summit of that princely edifice. The study, therefore, not the imitation, might be extremely serviceable to artists of genius and discernment."

493. Vanbrugh's principal work was Blenheim (whereof we give, in *figs.* 215. and 216.,

Fig. 216.

ELEVATION OF BLENHEIM.

the plan and principal elevation), a monument of the victories of Marlborough raised by a grateful nation. Its length on the north front from one wing to the other is 348 ft. The internal dimensions of the library are 130 by 32 ft. The hall is perhaps small compared with the apartments to which it leads, being only 53 ft. by 44, and 60 ft. high.

494. The execution of his design for Castle Howard, in Yorkshire, was commenced in 1702, and, with the exception of the west wing, was completed by him. The design possesses a much greater simplicity than that of Blenheim. There is a portico in the centre, and a cupola of considerable height and magnitude. The galleries, or wings, are flanked by pavilions. The living apartments are small; but for the comfort and convenience of the house, as an habitation, many improvements have been made since the time of Vanbrugh.

495. At Eastbury, in Dorsetshire, he built a spacious mansion for Mr. Doddington. The front of it, with the offices, extended 370 ft. We regret to say that it was taken down by the first Earl Temple, about the middle of the last century.

496. King's Weston, near Bristol, erected for the Honourable Edward Southwell. A beautiful feature in the house is the grouping of the chimneys, in which practice no artist has surpassed, nor perhaps equalled, him. This house is not, however, a favourable specimen of our architect's powers.

497. In the front which he executed to Grimsthorpe, in Lincolnshire, he indulged himself in an imitation of Blenheim and Castle Howard. The hall here is of noble dimensions, being 110 ft. in length, and 40 ft. in height, surmounted by a cupola.

498. Charles Howard, the third Earl of Carlisle, Deputy Earl Marshal in 1703, appointed Vanbrugh, Clarenceux king of arms, over the heads of all the heralds, who remonstrated, without effect, against the appointment. The cause of such an extraordinary promotion is supposed to have had its origin in the Earl's satisfaction with the works at Castle Howard. It was, however, altogether unjustifiable, for Vanbrugh was, from all accounts, totally ignorant of heraldry. He held the situations of surveyor of the works at Greenwich Hospital, comptroller general of the works, and surveyor of the gardens and waters. Though perhaps out of place in a history of architecture, we cannot resist the opportunity of mentioning that our artist was a dramatist of genius. *The Relapse*, *The Provoked Wife*, *The Confederacy*, and *Æsop*, according to Walpole, will outlast his edifices. He died at Whitehall, March 26. 1726. Vanbrugh can hardly be said to have left a legitimate follower; he formed no school. Archer, indeed, attempted to follow him, and seems the only one of his time that could appreciate the merit of his master. But he was too far behind him to justify our pausing in the history of the progress of British architecture to say more than that his best works are Heythrop, and a temple at Wrest. St. Philip's Church at Birmingham is also by him. "A chef d'œuvre of his absurdity," says Dallaway, "was the church of St. John's, Westminster, with four belfries," a building which has not inaptly been likened to an elephant on his back, with his four legs sprawling in the air.

## SECT. VIII.

GEORGE I.

499. Though the example of Wren was highly beneficial to his art, he does not seem to have been anxious to propagate his doctrines by precepts, for he had but one pupil who deserves a lengthened notice. That pupil was Nicholas Hawksmoor, who, at the age of eighteen, became the disciple of Sir Christopher, "under whom," says Walpole, "during life, and on his own account after his master's death, he was concerned in erecting many public edifices. Had he erected no other than the church of St. Mary Woolnoth, Lombard Street, his name would have deserved with gratitude the remembrance of all lovers of the art. This church has recently (on the opening of King William Street) been unfortunately disfigured on its southern side by some incompetent bungler on whom the patronage of the churchwarden luckily fell. Such is the fate of our public buildings in this country. The skill displayed by Hawksmoor in the distribution and design of St. Mary

Fig. 217. HALF ELEVATION HALF SECTION OF ST. MARY WOOLNETH.

lofty rusticated pedestal, relieved with blank recesses, which are repeated in the intervals below between the niches. The whole stands on a basement, whose openings, of course,

Fig. 218. PLAN OF ST. MARY WOOLNETH.

correspond to those above. The niches in the recesses are decorated with Doric columns on pedestals, and the top of the entablature of the order is level with the springing of each niche head running through on each side, so as to form an impost. The front is crowned with a block cornice, continued round the building, and the central part of the northern front is surmounted by a balustrade. We are not prepared to maintain that the whole of the details are in the purest taste; but the masses are so extremely picturesque, and so adapted to the circumstances of the aspect and situation, that their faults are forgotten. Not so the interior, which needs no apology. It is a combination of proportions, whose beauty cannot be surpassed in any similar example. The plan is nearly a square, whose north-west and south-west angles are truncated at angles of forty-five degrees, for the introduction of stairs. The leading lines are an inscribed square whose sides are equal to two thirds of the internal width, the remaining sixth on each side being assigned to the intercolumniations between the columns and the pilasters on the internal walls. The columns, twelve in number, are placed within the sides of the inscribed square, and at the angles are coupled at intervals of one diameter. The order is Corinthian; the columns are fluted, and crowned by an enriched entablature one quarter of their height. The space thus enclosed by the columns continues in a clerestory above, pierced on the four sides by semicircular windows, whose diameters are equal to one of the wide intercolumniations below. The height of this, including its entablature, is one half that of the lower order; thus, with its pedestal, making the total height of the central part of the

Woolnoth is not more than rivalled by the best productions of his master and instructor. We here give, in *figs.* 217. and 218., a half section, elevation, and plan of it. It was commenced in 1716, and finished in 1719. Not until lately was it seen to advantage. Lombard Street, in which it still partly stands, was narrow, and its northern elevation, the only one till lately properly seen, required, from its aspect, the boldest form of detail to give it expression, because of its being constantly in shade, and therefore experiencing no play of light except such as is reflected. This is composed with three large semicircular rusticated niches, each standing on a

church, equal to its extreme width. A sesquialteral proportion is thus obtained in section as well as plan. The eastern end is recessed square for an altar piece, and arched with a semicircular ceiling enriched with caissons. The galleries are admirably contrived, and in no way interfere with the general effect, nor destroy the elegance and simplicity of the design. The ceilings throughout are horizontal, and planned in compartments, whose parts are enriched. As regards construction, there is a very unnecessary expenditure of materials, the ratio of the superficies to the points of support being 1:0·263. Hawksmoor was not so happy in the church of St. George's, Bloomsbury, in which he has really made King George I. the head of the church by placing him on the top of the steeple, which we must, with Walpole, term a master-stroke of absurdity. But many parts of the building are highly deserving the attention of the student; and if the commissioners for new churches in these days had been content with fewer churches constructed solidly, like this, instead of many of the pasteboard excrescences they have sanctioned, the country, instead of regretting they ever existed, which will at no very remote period be the case, would have owed them a deep debt of gratitude. The only gratification we have on this point is, that a century, and even less, will close the existence of a large portion of them. Hawksmoor was deputy surveyor of Chelsea College and clerk of the works at Greenwich, and in that post was continued by William, Anne, and George I., at Kensington, Whitehall, and St. James's. Under the last named he was first surveyor of all the new churches and of Westminster Abbey, from the death of Sir Christopher Wren. He was the architect of the churches of Christ Church, Spitalfields, St. George, Middlesex, and St. Anne, Limehouse; rebuilt some part of All Souls, Oxford, particularly the new quadrangle completed in 1734, and was sole architect of the new quadrangle at Queen's. At Blenheim and Castle Howard he was associated with Vanbrugh, and at the last-named place was employed on the mausoleum. Among his private works was Easton Neston, in Northamptonshire, and the restoration to perpendicularity, by means of some ingenious machinery, of the western front of Beverley Minster. He gave a design for the Radcliffe Library at Oxford, and of a stately front for Brazenose. His death occurred on the 25th of March, 1736, at the age of near seventy.

500. Those acquainted with the condition of the country will be prepared to expect that the arts were not much patronised by George I. The works executed during his reign were rather the result of the momentum that had been imparted previous to his accession than of his care for them; and it is a consolation that the examples left by Inigo Jones had an effect that has in this country never been entirely obliterated, though in the time of George III., such was the result of fashionable patronage and misguided taste, that the Adames had nearly consummated a revolution. That reign, however, involved this country in so many disasters that we are not surprised at such an episode.

501. After the death of Hawksmoor, succeeded to public patronage the favourite architect of a period extending from 1720 to his death in 1754, whose name was James Gibbs, a native of Aberdeen, where he first drew breath in 1683. Though he had no claims to the rank of exalted genius, he ought not to have been the object of the flippant criticism of Walpole, whose qualifications and judgment were not of such an order as to make him more than a pleasant gossip. He certainly had not sufficient discernment properly to estimate the talents of Gibbs's works. Every critic knows how easily phrases may be turned and antitheses pointed against an artist whom he is determined to set at nought; of which we have before had an instance in the case of Sir John Vanbrugh; and we shall not here further dilate upon the practice. We will merely observe, that on the appearance of any work of art the majority of the contemporary artists are usually its best judges, and that in ninety-nine cases out of a hundred the public afterwards sanction their decision; and we will add, in the words of old Hooker, that "the most certain token of evident goodness is, if the generall perswasion of all men doe so account it;" and again, "although wee know not the cause, yet this much wee may know, that some necessarie cause there is, whensoever the judgement of all men generally or for the most part runne one and the same way." We do not, therefore, think it useful in respect of an artist of any considerable talent to repeat a criticism more injurious to the writer than to him of whom it was written.

502. The church of St. Martin's in the Fields is the most esteemed work of our architect. It was finished in 1726, as appears from the inscription on the frieze, at the cost of 33,017*l.* 9*s.* 3*d.* The length of it, including the portico, is twice its width, one third whereof, westward, is occupied by the portico and vestibule. The portico is hexastyle, of the Corinthian order, and surmounted by a pediment, in whose tympanum the royal arms are sculptured. The intercolumniations are of two diameters and a half, and the projection of the portico of two. Its sides are flanked by antæ in their junction with the main building, one diameter and a half distant from the receiving pilaster. The north and south elevations are in two stories, separated by a fascia, with rusticated windows in each. Between the windows the walls are decorated with pilasters of the same dimensions as the columns of the portico, four diameters apart; but at the east and west ends these elevations are marked by insulated columns coupled with antæ. The flanks are connected with the

prevailing lines in the portico by columns placed on the walls, recessed for the purpose, and coupled with antæ, whereby a play of light is produced, which imparts great effect to the other parts. The interior is divided into three unequal portions by a range on each side of four Corinthian columns, and two pilasters placed on pedestals, raised to the height of the pewing. From their insulated entablatures rises an elliptical ceiling, covering what may be called the nave. This ceiling is formed by *ares doubleaux*, between which the vault is transversely pierced in the spaces above the intercolumniations by semicircular arches springing from the top of the entablature of each column. Over what may be called the aisles, from the entablatures of the columns, semi-circular arches are turned and received northward and southward on consoles attached to the walls, and by their junction with the longitudinal arches from column to column pendentives are evolved, and thereby are generated small flat domes over the galleries. The altar is recessed from the nave in a large niche formed by two quadrants of circles, whose radius is less than one fourth of the whole width of the niche. It is vaulted semi-elliptically. Galleries are introduced on the north, south, and west sides of the church. On the two former sides they extend from the walls to the columns, against which the continuity of their mouldings is broken. The interior is highly decorated, perhaps a little too theatrically for the sombre habits of this country; but its effect is, on the whole, extremely light and beautiful. The tower and spire are, as in all the English churches of the Italian style, a sad blemish; but the taste of the day compelled their use, and we regret that the clergy still persist in considering them requisites. The length from the front upper step to the east wall (inclusive) is 159 ft. 6 in., and the breadth from north to south 79 ft. 4 in. The total area of the church is 12,669 ft., whereof the points of support occupy 2803 ft. The ratio, therefore, of the former to the latter is a 1 : 0.220, from which we may infer that the edifice exhibits no very extraordinary constructive skill. The span of the roof (*fig. 696.*), which is of the common king-post form, is 38 ft. Gibbs, unlike Wren, does not appear to have been guided in his leading proportions of this work by a series of ratios. The only point in which we perceive an approximation to such a system is in the length from the plinths of the columns of the portico, being just double the width of the church measured at the same level. The portico is well designed, and hitherto has not been equalled in London.

503. In the church of St. Mary le Strand, Gibbs was not so successful. There is no portion of its space on which the eye rests with pleasure. It is cut up into littlenesses, which, though not individually offensive, destroy all repose or notion of mass in the fabric. He built the new church at Derby, and executed some works at King's College, Cambridge, which last were not calculated to raise his reputation; but in the senate house of that university, he was more successful. In the Radcliffe Library at Oxford, his fame was maintained. It was completed in 1747, and thereon he was complimented with the degree of Master of Arts. This library is on the plan circular in general form, and rises in the centre of an oblong square, 370 ft. long, by 110 in width. Its cupola is 100 ft. in diameter, and 140 ft. high. It possesses no features of striking beauty, and yet is a most valuable addition to the distant view of Oxford, from whatever point of view it is seen. The interior is pleasing, and the disposition good. The books are arranged in two circular galleries, round a large central area. A description of this celebrated building was published with plans and sections, fol. 1747. Gibbs was the architect also of St. Bartholomew's Hospital. In 1728, he published a large folio volume of designs, including several of his works.

Fig. 219.

PLAN OF WANSLEY HOUSE.

504. Some works of considerable importance were erected during the reign of George I., by a countryman of the last-named architect, Colin Campbell, who is, however, more esteemed for three volumes he published of the principal buildings in England, under the name of the *Vitruvius Britannicus*. Of this work Lord Burlington was the original projector and patron. Afterwards, in 1767 and 1771, it was continued in two volumes, under the superintendence of Wolfe and Gandon, two architects of considerable reputation. Campbell's talents were not of a very high order, though Mereworth, in Kent, an imitation of the Villa Capra, built for Mildmay Earl of Westmorland, and Wansted House, in Essex, built in 1715, and pulled down in 1815, the latter especially, entitle him to be considered an artist of merit. Foreigners, whilst this last was in existence, always preferred it to any other of the great mansions of the country. Gilpin says of it, "Of all great houses, it best answers the united purposes of grandeur and convenience. The plan is simple and magnificent. The front extends 260 ft. A hall and saloon occupy the body of the house, forming the centre of each front. From these run two sets of chambers. Nothing can exceed their convenience. They communicate in one grand suite, and yet each, by the addition of a back stair, becomes a separate apartment. It is difficult to say whether we are better pleased with the grandeur and elegance without, or with the simplicity and contrivance within. Dimensions: Great hall, 51 ft. by 36; ball room, 75 by 27; saloon, 30 ft. square." As the building no longer exists, we give, in *figs.* 219. and 220., a

Fig. 220

ELEVATION OF WANSTEAD HOUSE.

ground plan and elevation of it. Campbell was surveyor of the works of Greenwich Hospital, and died in 1734.

505. The church at Greenwich, and a very large mansion at Blackheath for Sir Gregory Page, in the latter whereof much is said to have been borrowed from Houghton, but which has many years since disappeared, were, about 1718, erected by John James, of whom very little more is known than these works, and, in London, the churches of St. George, Hanover Square, and St. Luke's, Middlesex, the latter whereof has a fluted obelisk for a steeple. We ought, besides, to mention that he was employed by the Duke of Chandos, at Cannons, another building no longer in existence, and showing the frail tenure upon which an architect's reputation and fame is held. At the latter place, however, it may be questioned whether the remark strictly applies, inasmuch as he is said to have therein set taste and expense equally at defiance.

## SECT. IX.

### GEORGE II.

506. We do not altogether agree with Walpole in the observation that architecture resumed all her rights during this reign, though there is no doubt that the splendid (for the time) publications of Palladio, Jones, and examples of the antique recalled the taste of artists and their patrons the public. Men of genius were doubtless found to support the arts by their practice, and some high-minded patrons to encourage them in their labours. "Before," observes Walpole, "the glorious close of a reign that carried our arms and victories beyond where Roman eagles ever flew, ardour for the arts had led our travellers to explore whatever beauties of Grecian or Latin skill still subsisted in provinces once subjected to Rome, and the fine additions, in consequence of those researches, have established the throne of architecture in Britain while itself languishes in Rome."

507. Among the earliest of the architects of this reign was Thomas Ripley, a native of Yorkshire, at whom Pope sneers in the lines —

" Who builds a bridge that never drove a pile?  
Should Ripley venture, all the world would smile."  
*Imit. Horace, Ep. ii. S. 186.*

Ripley, it must be confessed, failed at the Admiralty, which was afterwards veiled by Mr. Adam's beautiful skreen since cruelly "cheated of its fair proportions" by the late architect to that Board, in order to make two coach entrances, which might, with the exercise of a little ingenuity, have been managed without defacing the design. It is difficult, now, to decide the exact share that Ripley had in the house for Lord Orford, at Houghton, for which Campbell appears to have furnished the original design. Walpole, whom we may presume to have known something about the matter, says they were much improved by Ripley. He published them in two volumes, folio, 1755—60. It is to be regretted that scarcely a single line of Pope, in matters of taste relative to the artists of his day, is of the smallest worth, so much did party and politics direct the shafts of the poet's malice. The plain truth is, that Ripley was the rival of Kent, the favourite of Lord Burlington, whose patronage it was absolutely necessary to enjoy before he could ensure the smiles of Pope. Ripley was comptroller of the Board of Works, and died in 1758.

508. Henry Herbert, Earl of Pembroke, an amateur of this reign, cannot pass unnoticed in the History of its Architecture. He much improved Wilton, where he built the Palladian Bridge; and it is highly honourable to his memory that, owing to his exertions, the qualifications of Labeyle for building Westminster Bridge were acknowledged in opposition to Hawksmoor and Batty Langley, the latter of whom was an ignorant pretender. Of this bridge Earl Henry laid the first stone in 1739, and the last in 1747. His works, besides those at Wilton, were, the new lodge in Richmond Park, the Countess of Suffolk's house at Marble Hill, Twickenham, and the Water House at Lord Orford's Park at Houghton. He died in 1751.

509. Before advancing our history another step, we have to notice another nobleman, whom to enrol among the number of her artists is an honour to England; and in speaking of Richard Boyle, the third Earl of Burlington and fourth Earl of Ossory, we so entirely agree in Walpole's eulogy of him, that we shall not apologise for transcribing it from that author's pages:—"Never was protection and great wealth more generously and judiciously diffused than by this great person, who had every quality of a genius and an artist, except envy. Though his own designs were more chaste and classic than Kent's, he entertained him in his house till his death, and was more studious to extend his friend's fame than his own." Again, he continues, "Nor was his munificence confined to himself and his own houses and gardens. He spent great sums in contributing to public works, and was known to chuse that the expense should fall on himself, rather than that his country should be deprived of some beautiful edifices. His enthusiasm for the works of Inigo Jones was so active that he repaired the church of Covent Garden, because it was the production of that great master, and purchased a gateway at Beaufort Gardens, in Chelsea, and transported the identical stones to Chiswick with religious attachment. With the same zeal for pure architecture, he assisted Kent in publishing the designs for Whitehall, and gave a beautiful edition of the 'Antique Baths, from the Drawings of Palladio,' whose papers he procured with great cost. Besides his works on his own estate, at Lonsborough, in Yorkshire, he new-fronted his house in Piccadilly, built by his father, and added the great colonnade within the court." This liberal-minded nobleman gave the credit of this design to Kent, though, as Kent did not return from Italy before 1729, it is certain that architect could have had little to do with it. His villa at Chiswick, now that of the Duke of Devonshire, was an original design, and not, as is generally supposed, an imitation of Palladio's Villa Capra at Vicenza. It was, however, too much in the Italian taste to be suitable to an English climate or to English comforts; hence its great external beauty extracted from Lord Chesterfield the well-known verses—

" Possessed of one great house of state,  
Without one room to sleep or eat,  
How well you build let flatt'ry tell,  
And all mankind how ill you dwell."

Lord Hervey also sported his little wit upon this little bijou, which its subsequent additions have not much improved, saying "that it was too small to inhabit, and too large to hang one's watch in."

510. The dormitory of Westminster School and the Assembly Room at York are beautiful examples of the great powers of Lord Burlington; but the house for Lord Harrington at Petersham, the Duke of Richmond's at Whitehall (pulled down), and General Wade's house in Great Burlington Street were not well planned, the latter especially, on which it was said by Lord Chesterfield, on account of its beautiful front, that "as the general could not live in it to his ease, he had better take a house over against it, and look at it." The Earl of Burlington was born in 1695, and died in 1753.

511. William Kent, a native of Yorkshire, where he was born in 1685, if he did not advance the art, was at least far from retarding or checking any progress it seemed likely

to make. Kent was a painter as well as an architect, though as the former very inferior to the latter; and to these accomplishments must be added those of a gardener, for he was the father of modern picturesque gardening. Kent's greatest, and, out of many, also his best work, was *Holkham*, in *Norfolk*, for the Earl of *Leicester*, the plan and elevations whereof were published in folio, 1761, by the late Mr. *Brettingham*, who had the unparalleled assurance to send them to the world as his own. The noble hall of this building, terminated by a vast flight of steps, produces an effect unequalled by anything similar to it in England. During, and, indeed, previous to, Kent's coming so much into employment, a great passion seems to have existed with the architects for ill-shaped, and, perhaps, almost grotesque, urns and globes, on every part where there was a resting-place for them. Kent not unfrequently disfigured his works in this way, but more especially so at the beginning of his career. The pile of building in *Margaret Street*, which will shortly have to make way for part of the new parliament houses, now, however, containing the law courts, a house at *Esher* for Mr. *Pelham*, the *Horse Guards*, and other buildings, which it is needless here to particularise, were erected under the designs of Kent, upon whom unbounded liberality and patronage were bestowed by Lord *Burlington* during the life of this artist, which terminated in 1748.

512. About 1733 appeared, we believe, the last of the stone churches with steeples, which the practice of *Wren* had made common in this country; this was the church of *St. Giles's* in the *Fields*, erected by *Henry Flitcroft*. The interior is decorated with *Ionic* columns resting on stone piers. The exterior has a rusticated basement, the windows of the galleries have semicircular heads, and the whole is surmounted by a modillion cornice. The steeple is 165 feet high, consisting of a square tower, the upper part decorated with *Doric* pilasters; above, it is formed into an octagon on the plan, the sides being ornamented with three quarter *Ionic* columns supporting a balustrade and vases. Above this rises an octagonal spire. Besides this, *Flitcroft* erected the church of *St. Olave*, *Southwark*, and the almost entire rebuilding of *Woburn Abbey* was from the designs and superintendence of that master, who died in 1769.

513. During the reign under our consideration, the city of *Bath* may be said to have almost arisen from the designs of *Wood*, who built *Prior Park* for Mr. *Allen*, the friend of *Pope*, and *Buckland* was erected by him for Sir *John Throckmorton*. *Wood* died in 1754. To him and to his scholars *Bath* is indebted for the designs of *Queen Square*, the *Parades*, the *Circus*, the *Crescent*, the *New Assembly Room*, &c. The buildings of this city possess various degrees of merit, but nothing so extraordinary as to call for more than the mere notice of them. We are by no means, for instance, disposed to agree with *Mitford*, who reckons the crescent of *Bath* among "the finest modern buildings at this day existing in the world!"

---

## SECT. X.

### GEORGE III.

514. Though the works of the architects about to follow, belong partially to the preceding reign, they are only properly to be noticed under that of *George III.* Without a lengthened account of them, we commence with the mention of the name of *Carr* of *York*, who was much employed in the northern counties, where he built several noble residences, particularly that for Mr. *Lascelles*, afterwards Lord *Harewood*, and a mausoleum in *Yorkshire* for the late Marquis of *Rockingham*. *Paine* was engaged at *Workshop Manor*, *Wardour Castle*, and *Thorndon*; and *Horne*, whose county sessions-house and prison at *Warwick* exhibit considerable genius, was a promising artist, prematurely cut off. His talent was not confined to the *Italian style*, as may be learnt from reference to the church at *Tetbury* in *Gloucestershire*, and a triangular tower in the Duke of *Norfolk's* park at *Arundel*.

515. At a early part of the reign of *George III.*, architecture was cultivated and practised here with great success by *Robert Taylor*, afterwards knighted. His best compositions were designed with a breadth and intimate knowledge of the art, that prove him to have been abundantly acquainted with its principles. That he was not always successful, the wings of the *Bank*, now removed, were a proof. Of his works sufficient would remain to corroborate our opinion, if only what is now the *Pelican Office* in *Lombard Street* existed. We believe it was originally built for Sir *Charles Asgill*, and ruined by the directors of the *Pelican* when they took to the place. There are, however, also to attest the ability of Sir *Robert Taylor*, Sir *Charles Asgill's* villa at *Richmond*, and his own house in *Spring Gardens*. After his visit to *Italy* he commenced his practice in sculpture, in which branch of the arts he has left monuments in *Westminster Abbey* and elsewhere; but he afterwards devoted himself to architecture alone. Among his works were a dwelling house for Sir *P. Taylor*,

near Portsdown Hill, a house in Piccadilly for the Duke of Grafton, a mansion in Herts for Lord Howe; Stone Buildings, Lincoln's Inn; Ely House, Dover Street, a very clever composition; Sir John Boyd's at Danson, near Shooter's Hill; the beautiful bridge at Henley on Thames, and Lord Grimstone's at Gorhambury. He had for some time a seat at the Board of Works, was surveyor to the Admiralty, the Bank, and other public bodies. His reputation was unbounded, and met with reward from the public. Sir Robert Taylor died in 1788 at the age of seventy-four.

516. Contemporaneous with the last-named artist, was one to whom the nation is indebted for first-bringing it to an intimate acquaintance with the works of Greece, to which he first led the way. The reader will, of course, anticipate us in the name of James Stuart, who began his career as a painter. After some time passed in Greece, he, in conjunction with Nicholas Revett, about the year 1762, published the well-known *Antiquities of Athens*, from which he acquired the soubriquet of *Athenian*. The public taste was purified by a corrected knowledge of the buildings of Greece, especially in respect of the form, composition, and arrangement of ornament; but we doubt whether mischief was not for a time induced by it, from the absurd attempt, afterwards, to adapt, without discrimination, the pure Greek porticoes of the temples of Greece to public and private buildings in this country, often with buildings with which they have no more natural relation than the interior arrangement of a church has with that of a theatre. The architects of our own time seem, however, at last to be aware of the impossibility of applying with success the forms of Grecian temples to English habitations; and a better system has been returned to, that of applying to every object a character suitable to the purposes of its destination. We consider Stuart's best work the house, in St. James's Square, which he built for Lord Anson. Among other works, he executed Belvedere, in Kent, for Lord Eardley; a house for Mrs. Montague, in Portman Square; the chapel and infirmary of Greenwich Hospital; and some parts of the interior of Lord Spencer's house, in St. James's Place. Stuart died in 1788, at the age of seventy-five. His collaborateur, Revett, shared with him a portion of the patronage of the public. He survived him till 1804, when he died at the advanced age of eighty-two years. He was employed on the eastern and western porticoes of Lord De Spencer's house at West Wycombe, and on some temples. For Sir Lionel Hyde he built the church of Ayot St. Lawrence, Herts, the front whereof is a Doric portico crowned with a low Grecian pediment, and on each side an Ionic colonnade connects the centre with an elegant cenotaph. He also built a portico to the eastern front of Standlunch, in Wiltshire, for Mr. Dawkins.

517. The chasteness and purity which the two last-named architects had, with some success, endeavoured to introduce into the buildings of England, and in which their zeal had enlisted many artists, had to contend against the opposite and vicious taste of Robert Adam, a fashionable architect, whose eye had been ruined by the corruptions of the worst period of Roman art. It can be scarcely believed, the ornaments of Diocletian's palace at Spalatro should have loaded our dwellings contemporaneously with the use among the more refined few of the exquisite exemplars of Greece, and even of Rome, in its better days. Yet such is the fact; the depraved compositions of Adam were not only tolerated, but had their admirers. It is not to be supposed that the works of a man who was content to draw his supplies from so vitiated a source will here require a lengthened notice. Yet had he his happy moments; and that we may do him strict justice, we not only mention, but

Fig. 221.

ELEVATION OF KEDLESTONE.

present to the reader, in *figs. 221. and 222.*, the ground plan and elevation of Kedleston, in Derbyshire, which he erected for Lord Scarsdale. The detail of this is, indeed, not exactly what it ought to have been; but the whole is magnificently conceived, and worthy of any master. Adam died at the age of ninety-four, in 1792; and, besides the Adelphi, in the Strand, which he erected on speculation, he was engaged at Luton Park, in Bedfordshire, for the Earl of Bute; at Caenwood, near Hampstead, for Lord Mansfield; at Shelburne House, in Berkeley Square, now Lord Lansdowne's, well planned, but ill designed, a meagre affair; the disgraceful gateway at Sion, near Brentford; and on part of the Register Office at Edinburgh. None, however, would now do credit to a mere tyro in the art except the first named.

Fig. 222.

PLAN OF KEDLESTON.

518. Previous to the accession of George III. it had been considered by his tutors necessary to complete his education by the study requisite to give him some acquaintance with the art. We venerate the memory of that monarch as an honest good man, but are compelled to say that the experiment of inoculating him with a taste for it was unsuccessful, for during his reign all the *bizareries* introduced by Adam received no check, and seeing that Adam and Bute were both from the north, we are rather surprised that his education was not in this respect committed to the former instead of Sir William Chambers, whom, as one of the first architects of the day, it is incumbent upon us now to introduce. We believe that whatever was done to forward the arts, owes a large portion of its effect to that celebrated man; and it is probable, with the worthy motives that actuated the monarch, and the direction of his taste by that individual, much more would have been accomplished, but for the heavy and disastrous wars which occurred during his reign, and the load of debt with which it became burthened. The works of Chambers are found in almost every part of England, and even extended to Ireland; but we intend here chiefly to restrict ourselves to a short account of Somerset House, his largest work, in which, though there be many faults, so well did he understand his art, that it is a matter of no ordinary difficulty, and indeed requires hypercriticism, to find anything offensive to good taste in the detail.

519. This work was commenced in 1776, and stands on an area of 500 ft. in depth, and 800 ft. in width. The general interior distribution consists of a quadrangular court, 343 ft. in length, and 210 ft. in width, with a street or wide way running from north to south, on its eastern and western sides. The general termination towards the river is a terrace, 50 ft. wide, whose level is 50 ft. above that of the river, and this occupies the whole length of the façade in that direction. The front towards the Strand is only 135 ft. long. It is composed with a rustic basement, supporting ten Corinthian columns on pedestals, crowned by an attic, extending over the three central intercolumniations, flanked by a balustrade on each side. The order embraces two stories. Nine large arches are assigned to the basement, whereof the three central ones are open for the purpose of affording an entrance to the great court. On each side of them, these arches are occupied by windows of the Doric order, decorated with pilasters, entablatures, and pediments. The key stones are carved in alto-relievo, with nine colossal masks, representing the ocean, and the eight principal rivers of Great Britain. The three open arches of entrance before mentioned lead to a vestibule, which connects the Strand with the large quadrangular court, and serves also as the access to those parts of the building, till lately occupied by the Royal Academy, and on the opposite or eastern side to the Royal Society and the Society of Antiquaries, the entrances whereto are within the vestibule. This is decorated with columns of the Doric order, whose entablature supports a vaulted ceiling. The front of this pile of building towards the quadrangle, is 200 ft. in extent, being much more than the length of that towards the Strand; the style, however, of its decoration is correspondent with it, the principal variation being in the use of pilasters instead of columns, and in the

doors and windows. The front next the Thames is ornamented in a similar manner to that already described. It was originally intended that the extent of the terrace should have been 1100 ft. This last is supported by a lofty arcade, decorated towards the ends with coupled Tuscan columns, whose cornice is continued along the whole terrace. The edifice was at the time the subject of much severe criticism, and particularly from the pen of a silly engraver of the name of Williams, under the name of Antony Pasquin; but the censures he passed on it, the author being as innocent of the slightest knowledge of the art as most of the writing architectural critics of the present day, were without foundation, and have long since been forgotten.

520. In the year 1759, Sir W. Chambers published a Treatise on the decorative part of civil architecture, whereof it was the lot of the writer to publish an enlarged edition in 1825. This work, as far as it goes, still continues to be a sort of text-book for the student; but as it is merely what its title imports, without touching on the historical or practical parts of the art, it is so far incomplete. Chambers held the office of surveyor general, and died in 1796.

521. Among the architects of George III.'s reign, we must not forget Robert Mylne, the architect of Blackfriar's Bridge, constructed between 1760 and 1768; Holland, who erected Carlton House for George IV. when Prince of Wales, and Drury Lane Theatre, neither of which buildings now exists; Dance, the architect of Newgate, St. Luke's Hospital, and many buildings about the city of London, to whose corporation he was architect; and, lastly, Willey Reveley, a pupil of Chambers, who followed the steps of Stuart and visited Athens and the Levant. He was the editor of the third volume of the *Antiquities of Athens*, and died prematurely in 1799. He built the new church at Southampton, and offered some beautiful designs for the new baths at Bath, which, however, were not adopted. We have now concluded a general view of the history of the art, from its dawn in this country to the end of the reign of George III.; having enumerated the professors of later days most worthy to be recorded. Further we should not be able to pursue our inquiry without coming so into contact with our cotemporaries and their connections, that our office, if not dangerous and fearful, might be unpleasant, and we must here close. We regret we cannot think our national architecture advances in the same ratio that the facilities of study in the present day would indicate. This is not to be imputed so much to the professors of the art as to the way in which it is treated by Government and the public; witness the National Gallery, made a job by a minister for an incompetent artist. "It is a national, a social misfortune," says the late James Spiller, "that to the scientific study of this noble art, there is no reasonable, much less liberal encouragement. It is degraded and crushed under the most despicable spirit of calculation and parsimony!" If ever a death-blow was aimed at the art, that was done by the commissioners for building the recent new churches. What artist could hope to become celebrated under their pinching ordinances, competitions, and contracts, with their accompanying legal din and "smithery?" Far different was the conduct of those commissioners to whom Queen Anne entrusted the building of her churches, or their existence would have been matter only of history, a category that we are certain will apply, at the end of a century, to many of those of the present day.

## BOOK II.

## THEORY OF ARCHITECTURE.

## CHAP. I.

## ARITHMETIC AND ALGEBRA.

## SECT. I.

## INTRODUCTION.

522. THE abstract relations of quantity and figure ought to be thoroughly understood by the architect, that he may be able to prepare the designs which he has conceived, in a manner suitable for execution, and, when executed, to possess stability. The form and mechanical effect of each single block in a building depends on its position, and the form of one of its parts limits the forms of others. In groups of bodies, these limitations are still more perplexing; hence we must have recourse to the most easy and accurate means of ascertaining the practicable conditions which will produce the desired effect. To this end we propose to give a short and simple course of the elements of arithmetic and analysis, as our own experience informs us that occasions arise in the practice of architecture which require all the aid that science can afford. Those who have studied most closely, know that they have not acquired too much; whilst those who have not studied at all have to depend on the skill of others, and, like all similar dependents, become more or less the dupes of those they employ.

523. That which is capable of increase or diminution is called *magnitude* or *quantity*. Hence the different kinds of magnitude must be many. Mathematics, generally speaking, is the *science of quantity*, or that which investigates the means of measuring quantity. Now we cannot measure or determine any quantity except by pointing out its relation to some other known quantity, so that the determination or the measure of magnitudes of all kinds is the making any one known magnitude of the same species the *measure* or *unit* for determining the proportion of the proposed magnitude to this known measure. This proportion being always expressed by numbers, a number is but the proportion of one magnitude to another, arbitrarily assumed as the unit. Hence all magnitudes may be expressed by numbers, and the foundation of all mathematical science must be laid in a study of the science of numbers, and in an examination of the different methods of calculation involved in it. In Algebra, or analysis numbers, which represent quantities, are alone considered, without respect to the different kinds of quantity. The latter are the subject of other branches of mathematics. Arithmetic is the *science of numbers properly so called*, extending only to certain methods of calculation which occur in common practice. Algebra comprehends all the cases that can exist in the calculation of numbers.

## SIGNS + AND -.

524. (1.) When one number is to be added to another, the sign + (*plus*) is used, and is placed before the second number. Thus,  $5 + 3$  denotes that 3 is to be added to the number 5, the sum whereof every body knows to be 8. The same sign may be used to connect several numbers, thus  $7 + 9 + 12 + 81$  signifies that to the number 7 we must add 9, 12, and 81, which make 109. All this is evident, but in Algebra, in order to generalise numbers, they are represented by letters as *a*, *b*, *c*, *d*, &c.; thus  $a + b + c + d$  signifies the sum of the numbers represented by those letters.

525. (2.) To subtract one number from another the sign - (*minus*) is used, which is placed before the number to be subtracted; thus  $10 - 6$  signifies that the number 6 is to be taken from the number 10, so that the expression is equivalent to the number 4. So of several numbers; as, for instance,  $62 - 6 - 15 - 31$  signifies that 6 is to be taken from 62,

the remainder is 56; 15 taken from that remainder leaves 41; lastly, take from this 31, and the remainder is 10, which is the value of the expression. We might, however, have taken the sum of the numbers 6, 15, and 31 or 52 at once from 62, and the remainder is 10, as before.

526. It is easy, therefore, to determine the value of expressions in which both the signs + plus and - minus are found; for example,  $16 - 4 - 7 + 3 - 1$  is the same as 7. For we have only to collect the numbers with the sign + before them, and subtract from their sum those that have the sign -. Thus, the sum of 16 and 3 is 19; that of 4, 7, and 1 is 12; and 12 being taken from 19 the remainder is 7. It must be remembered that in the expression the sign + is supposed to stand before the number 16; and that the above expression might have been arranged thus:  $16 + 3 - 4 - 7 - 1$ , or  $3 - 1 - 4 - 7 + 16$ , or  $3 + 16 - 1 - 7 - 4$ . If, instead of numbers, we use letters, no more difficulty occurs; for example —

$$a - b - c + d - e$$

signifies that certain numbers are expressed by  $a$  and  $d$ , and that from them or their sum the numbers expressed by the letters  $b$ ,  $c$ , and  $e$ , having the sign - before them, are to be subtracted. Hence attention is necessary to the sign prefixed to each number, for in algebra simple quantities are numbers considered with respect to the signs which affect them. Those quantities before which the sign + is found are called *positive quantities*, and those affected by the sign - are called *negative quantities*. To illustrate this, let us suppose a man having 1000*l.*, but owing 400*l.*, it is evident his real wealth is only 1000*l.* - 400*l.*, 600*l.* Thus, negative numbers may be considered as debts, because positive numbers represent real possessions, and we may, indeed, say that negative numbers are less than nothing. For, take a man having nothing, and at the same time owing 100 pounds, it is clear he has 100 pounds less than nothing; for, if he had a present of 100 pounds made him to pay his debts, though he would be richer than before, he would still be at the point nothing. So, therefore, as positive numbers are clearly greater than nothing, negative numbers are less than nothing. Now, positive numbers are obtained by adding 1 to 0, that is, to nothing, and by thus increasing them from unity. This is the origin of the series called *natural numbers*, of which the following are the leading terms of the series:  $0 + 1 + 2 + 3 + 4 + 5 + 6 + 7 + 8 + 9 + 10$ , and so on to infinity. But if, instead of adding, we perpetually subtract unity, we have a series of negative numbers, thus:  $0 - 1 - 2 - 3 - 4 - 5 - 6 - 7 - 8 - 9 - 10$ , &c. to infinity. These numbers, whether positive or negative, are called whole numbers or *integers*, either greater or less than nothing. They are so called to distinguish them from fractions and other kinds of numbers, which will be hereafter noticed. Thus, between 2 greater by a unit than 1, it is easy to conceive an infinity of numbers greater than 1, yet all less than 2; for imagine a line of 2 ft. long and another 1, it is evident that an infinite number of lines may be drawn, all longer than 1 ft., but not so long as 2 ft. That a precise idea may be formed of negative quantities, the reader must keep in mind that all such expressions as  $+1 - 1$ ,  $+2 - 2$ ,  $+3 - 3$ , &c. are equal to 0, and that  $+2 - 5$  is equal to  $-3$ . For, if a person has 2 pounds and owes 5, he has not only nothing, but still owes 3 pounds; and the same observation holds true with respect to letters, which represent numbers, thus  $+a - a$  is 0. But, if the value of  $+a - b$  is wanted, two cases are to be considered: first, if  $a$  is greater than  $b$  it must be subtracted from  $a$ , and the remainder, with the sign + placed or understood before it, is the value sought; secondly, if  $a$  is less than  $b$ ,  $a$  is to be subtracted from  $b$ , and the remainder must have the negative sign placed before it.

#### MULTIPLICATION OF SIMPLE QUANTITIES.

527. (3.) In the multiplication of simple quantities, where two or more equal quantities are added together, the expression of their sum may be abridged thus: —

$$\begin{aligned} a + a & \text{ is the same as } 2 \times a, \\ a + a + a & \dots \dots \dots 3 \times a, \\ a + a + a + a & \dots \dots \dots 4 \times a, \text{ and so on;} \end{aligned}$$

where  $\times$  is the sign of multiplication.

Thus we obtain an idea of multiplication; for in the above, it must be observed that  $2 \times a$  signifies 2 times  $a$ ,  $3 \times a$  signifies three times  $a$ ,  $4 \times a$  four times  $a$ . But this form is abbreviated by simply putting the number before the letter; thus,  $a$  multiplied by 3 is expressed  $3a$ :  $b$  multiplied by 5 is  $5b$ :  $c$  taken but once, or  $1c$ , is no more than  $c$ . Hence the multiplication of such products by other numbers is simple enough, for

$$\begin{aligned} 2 \text{ times } 3a & \text{ is equal to } 6a \\ 3 \text{ times } 4b & \dots \dots \dots 12b \\ 7 \text{ times } 7x & \dots \dots \dots 49x \end{aligned}$$

and these products may be further multiplied at pleasure.

528. Suppose both the numbers be represented by letters, we have only to place one before the other, and the process is complete; thus  $a$  multiplied by  $b$  is  $ab$ ; and if again we multiply this product by  $pg$ , the result is  $abpg$ . The order of the letters is no consequence; for suppose  $a$  to represent 5, and  $b$  6, then  $ba$  or  $ab$  equally represent  $6 \times 5$  and  $5 \times 6$ , which give the same product. But in the use of common numbers this cannot be done; for were we to write 34 for 3 times 4, we should have 34 instead of 12. If the sign  $\times$  is omitted, it is usual to place a point between the figures; thus,  $1.2.3.4.5$  is 120, as is  $1 \times 2 \times 3 \times 4 \times 5$ . Hence, if we meet with the expression  $2.3.4.xyz$ , it means that 2 is to be multiplied by 3, and the product by 4; and that product first by  $x$ , then by  $y$ , and lastly by  $z$ , hence this may be abridged into  $24xyz$ .

529. The result arising from the multiplication of two numbers is called a *product*, and the numbers or letters are called *factors*.

530. In the case of positive numbers being multiplied into each other, no doubt can remain of the products being positive, for  $+a \times +b$  must necessarily give  $ab$ . But the multiplication of  $+a$  by  $-b$ , or of  $-a$  by  $-b$ , requires examination. Suppose  $-a$  multiplied by 3; now, as  $-a$  may be taken as a debt, if multiplied by 3 it is three times greater; hence the product must be  $-3a$ . And if that be multiplied by  $+b$ , it is evident the debt is still increased by the action of  $b$  upon it; it becomes  $-ba$ , or, which is the same thing,  $-ab$ . On this account it is evident that if a positive be multiplied by a negative quantity, the product becomes worse, or, if the expression might be allowed, more negative. From this follows the rule, that  $+ \text{ by } +$  is always *plus*, and that  $+ \text{ by } -$ , on the contrary, gives a *minus* quantity. But the case in which  $-$  is multiplied by minus, that of  $-a$  by  $-b$ , requires consideration. There can be no doubt that the product is  $ab$ ; the sign, however, to be prefixed to it is at first sight not so clear. Now we have seen that it cannot be  $-$ , for  $-a$  multiplied by  $+b$  gives  $-ab$ , and  $-a$  by  $-b$ , cannot produce the same result as  $-a$  by  $+b$ ; hence it must produce a contrary result, that is  $+ab$ , and hence results the following rule:  $-$  multiplied by  $-$  produces  $+$  just in the same manner as  $+$  by  $+$ . This is more briefly expressed in the following terms, *Like signs multiplied together give +, unlike or contrary signs give -*, whereof take as an example the multiplication of the following numbers,  $+a, -b, -c, +d$ . First  $+a$  multiplied by  $-b$  makes  $-ab$ , this by  $c$  gives  $+abc$ , and this last by  $+d$  gives  $+abcd$ .

531. It remains only to show how to multiply numbers that are themselves products. Now, to multiply the number  $ab$  by the number  $cd$ , it is manifest, from what has been said, that the product is  $abcd$ , and that it is obtained by first multiplying  $ab$  by  $c$ , and the product by  $d$ . Or, if we had to multiply 36 by 12, 12 being equal to 3 times 4, we should first multiply 36 by 3, and the product 108 by 4, in order to have the whole product of the multiplication of 12 by 36, or 432. But, if we have to multiply  $5ab$  by  $3xy$ , we may write  $3xy \times 5ab$ ; but, as the order of the numbers is indifferent, it is better, and is the custom, to place the common numbers before the letters, and to express the product thus:  $5 \times 3abxy$ , or  $15abxy$ ; 5 times 3 being 15, so  $6abc$  by  $7xy$  gives  $42abcxy$ .

#### WHOLE NUMBERS IN RESPECT TO THEIR FACTORS.

532. A product, as we have seen, is generated by the multiplication of two or more numbers. These are called *factors*. Thus,  $abcd$  are the factors of the product  $abcd$ . All whole numbers cannot result from such a multiplication: those which are in that predicament have not any factors. Thus, 4 is produced by  $2 \times 2$ , 6 by  $2 \times 3$ , 8 by  $2 \times 2 \times 2$ , 27 by  $3 \times 3 \times 3$ , &c. But the numbers 2, 3, 5, 7, 11, 13, 17, &c. cannot be represented by factors, unless, for the purpose, we make use of unity, and represent, for instance, 2 by  $1 \times 2$ . Now, as numbers which are multiplied by 1 remain the same, unity cannot be reckoned as a factor. Hence, all numbers, such as 2, 3, 5, 7, &c., which cannot be represented by factors, are called *simple*, or *prime numbers*, whereas others, as 4, 6, 8, 9, 10, 12, 14, 15, 16, 18, &c., which can be represented by factors, are called *compound numbers*: *simple or prime numbers* consequently deserve particular attention, inasmuch as they do not result from the multiplication of two or more numbers; and it is worthy of observation, that in writing these numbers in succession as they follow each other, thus, 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, &c., no regular order is perceptible, their increments being sometimes greater, sometimes less, and, as yet, no law which they follow has been discovered.

533. All *compound numbers* which may be represented by factors have prime numbers for their factors; for if a factor is found which is not a prime number, it may be decomposed and represented by two or more prime numbers. Thus, if we represent the number 30 by  $5 \times 6$ , 6, not being a prime number, might have been represented by  $2 \times 3$ , that is  $5 \times 2 \times 3$ , in which the numbers are all prime; numbers equally represent 30.

There is much difference between compound numbers, which may be resolved into prime numbers; some have only two factors, others three, and others still more. Thus we have seen that

4 is the same as . . . . . $2 \times 2$	6 is the same as . . . . . $2 \times 3$
8 . . . . . $2 \times 2 \times 2$	9 . . . . . $3 \times 3$
10 . . . . . $2 \times 5$	12 . . . . . $2 \times 3 \times 2$
14 . . . . . $2 \times 7$	15 . . . . . $3 \times 5$
16 . . . . . $2 \times 2 \times 2 \times 2$	and so on.

The analysis, therefore, of any number, or the resolution of it into simple factors, is easily accomplished. Take, for instance, the number 360. First, it may be represented by  $2 \times 180$ . Then 180 is equal to  $2 \times 90$ , and

$$\left. \begin{array}{l} 90 \\ 45 \\ 15 \end{array} \right\} \text{ is the same as } \left\{ \begin{array}{l} 2 \times 45 \\ 3 \times 15 \\ 3 \times 5 \end{array} \right.$$

So that the number 360 may be represented by these simple factors,  $2 \times 2 \times 2 \times 3 \times 3 \times 5$ , since these numbers multiplied together produce 360. This shows that prime numbers cannot be divided by other numbers, and that the simple factors of compound numbers are most conveniently found by seeking the prime numbers, by which compound numbers are divisible.

#### DIVISION OF SIMPLE QUANTITIES.

534. The separation of a number into two or more equal parts is called *division*, which enables us to determine the magnitude of one of those parts. For instance, suppose we wish to separate 12 into three equal parts, we find, by division, that each of those parts is equal to 4. The number to be divided is called the *dividend*, the number of equal parts into which it is to be separated is called the *divisor*, and the magnitude of one of the parts determined by the division is the *quotient*: thus, in the example, —

12 is the dividend,  
3 is the divisor,  
4 is the quotient.

From this it is evident that if we divide the number 2 into two equal parts, one of those parts, or the quotient taken twice, is exactly the number proposed; and so, if a number is to be divided by 3, the quotient thrice taken must again give the same number. Hence follows the general rule that the *quotient multiplied by the divisor reproduces the dividend*. The dividend, indeed, may be considered a product, whereof one factor is the divisor and the other the quotient. For, if we have 40 to divide by 8, we have to find a product in which one of the factors is 8, and another factor which multiplied by it may give 40. Now  $5 \times 8$  is a product which answers the hypothesis, and therefore 5 is the quotient of 40 divided by 8.

535. Generally, a number  $ab$  divided by  $a$  gives a quotient  $b$ , because  $a$  multiplied by  $b$  gives the dividend  $ab$ . So, if we have to divide  $ab$  by  $b$ , the quotient must be  $a$ . In short, the whole operation of division consists in representing the dividend by two factors whereof one is equal to the divisor and the other to the quotient; thus the dividend  $abc$  divided by  $a$  gives  $bc$ , for  $a$  multiplied by  $bc$  produces  $abc$ ; and, similarly,  $abc$  divided by  $b$  gives  $ac$ , and  $abc$  divided by  $c$  gives  $b$ . So  $16xy$  divided by  $4x$  gives  $4y$ , inasmuch as 4 times  $x$  multiplied by 4 times  $y$  produces  $16xy$ ; but had  $16xy$  been divided by 16, the quotient must have been  $xy$ .

536. A number  $a$  is the same as  $1a$ ; hence, if  $a$  or  $1a$  is to be divided by 1 the quotient must be the same number  $a$ ; but if the same number  $a$  or  $1a$  be divided by  $a$ , the quotient must be 1.

537. The dividend cannot always be represented as the product of two factors, whereof one is equal to the divisor; in which case other expressions must be had recourse to. Thus, in dividing 19 by 6, it is obvious that the number 6 is not a factor of 19, for  $6 \times 3$  is but 18, and therefore too small, and  $6 \times 4$  produces 24, which is too large; from which it is evident that the quotient is greater than 3 and less than 4. To determine this exactly, a species of numbers called *fractions* is used, whereof we shall hereafter treat. But previous to that, let us investigate the number which nearest approaches to the true quotient, with attention to the *remainder* left, thus: —

$$\begin{array}{r} 6) 19(3 \\ 18 \\ \hline 1 \end{array}$$

where the dividend is 19, the divisor 6, the quotient 3, leaving a remainder of 1. Now, if we multiply the divisor 6 by the quotient 3, and thereto add the remainder, we have the dividend, and this proves the correctness of the division; for 3 multiplied by 6 produces 18, to which, if the remainder 1 be added, we have 19, the dividend.

538. Here it must be observed, in respect of the signs  $+$  and  $-$ , that  $+ab$  divided by  $+a$  must be  $+b$ ; for it is evident that  $+a$  multiplied by  $+b$  gives  $+ab$ . But, if  $+ab$  be divided by  $-a$ , the quotient must be  $-b$ , because  $-a$  multiplied by  $-b$  produces  $+ab$ . Suppose the dividend  $-ab$  divided by  $+a$ , the quotient must be  $-b$ , because  $-b$  multiplied by  $+a$  makes  $-ab$ . Lastly, the dividend  $-ab$  divided by  $-a$  must have for its quotient  $+b$ , for the dividend  $-ab$  is produced by  $-a$  by  $+b$ .

539. In division, therefore, the same rules hold respecting the signs  $+$  and  $-$  as in multiplication; namely, —

$+$  by  $+$  give  $+$  and  $+$  by  $-$  give  $-$ ,  
 $-$  by  $+$  give  $-$  and  $-$  by  $-$  give  $+$ ,

or, as it is usually expressed, *like signs give plus*, and *unlike signs give minus*.

Thus, dividing  $21xy$  by  $-3y$ , the quotient is  $-7x$ ; and

$-40pq$  divided by  $+4p$  gives  $-10q$ ;

and  $-72xyz$  divided by  $-8y$  gives  $+9xz$ ;

for  $-8y$  multiplied by  $+9xz$  makes  $-9 + 8xyz$ , or  $-72xyz$ .

#### THE PROPERTIES OF INTEGERS AS RESPECTS THEIR DIVISORS.

540. Some numbers are, it has been seen, divisible by certain divisors, others are not so. Let us look to this difference between them. Take the divisors 2, 3, 4, 5, 6, 7, 8, 9, 10, &c.

541. Now in the divisor 2 the numbers it will exactly divide are manifestly 2, 4, 6, 8, 10, 12, &c., in which the series increases uniformly by 2, and they are called *even numbers*. But in the numbers 1, 3, 5, 7, 9, 11, 13, 15, &c. there is an uniformly less or greater number by unity than in the former not divisible by 2 without a remainder 1: these are called *odd numbers*.

542. The general expression  $2a$  includes all the even numbers, for they are obtained by successively substituting the integers 1, 2, 3, 4, 5, 6, 7, &c.; and for this reason the odd numbers are comprehended in the expression  $2a + 1$ , because  $2a + 1$  is greater by unity than the even number  $2a$ .

543. In the second place, suppose 3 to be the divisor, the numbers it will exactly divide are 3, 6, 9, 12, 15, 18, 21, &c., which numbers are comprehended in the expression  $3a$ , for dividing  $3a$  by 3 the quotient is  $a$  without a remainder. All other numbers that we would divide by 3 will give 1 or 2 for a remainder; and hence they are of two kinds: first, those leaving the remainder 1 after the division, which are 1, 4, 7, 10, 13, 16, &c., and are contained in the expression  $3a + 1$ ; second, those in which 2 is the remainder, and these are 2, 5, 8, 11, 14, 17, 20, and these may be expressed  $3a + 2$ ; so that all these numbers may be expressed by  $3a, 3a + 1$ , or by  $3a + 2$ .

544. Suppose 4 to be the divisor, it will divide the following numbers, 4, 8, 12, 16, 20, 24, &c., which increase uniformly by 4, and are comprehended in the expression  $4a$ . All other numbers not divisible by 4 may leave the remainder 1, or be greater by 1 than the former, as 1, 5, 9, 13, 17, 21, &c., and may be comprehended in the expression  $4a + 1$ : or they may give 2 as a remainder, as 2, 6, 10, 14, 18, 22, &c., and be expressed by  $4a + 2$ ; or, lastly, they may give the remainder 3, and as 3, 7, 11, 15, 19, 23, &c., and be represented by the expression  $4a + 3$ . All possible integer numbers are hence contained in one or other of the four expressions  $4a, 4a + 1, 4a + 2, 4a + 3$ .

545. If the divisor is 5 it is nearly the same, for all numbers divisible by it are comprehended in the expression  $5a$ , and if not divisible by 5 they may be reduced to one of these expressions,  $5a + 1, 5a + 2, 5a + 3, 5a + 4$ , and so we may go on to the greatest divisors.

546. It is necessary to keep in mind, as we have noticed in a previous passage on the resolution of numbers into their simple factors, that all numbers among whose factors are found 2 or 3, or 4, or 5 or 7, or any other number, are divisible by those numbers. For example, 48 being equal to  $2 \times 2 \times 3 \times 4$ , it is clear that 48 is divisible by 2 and by 3 and by 4.

547. As the general expression  $abcd$  is not only divisible by  $a$  and  $b$ , and  $c$  and  $d$ , but also by

$ab, ac, ad, bc, bd, cd$ ;

and by  $abc, abd, acd, bcd$ ;

and, lastly, by  $abcd$ , which is its own value:

it is clear that 48, or  $2 \times 2 \times 3 \times 4$ , may be divided not only by those simple numbers, but by those composed of two of them, that is, by 4, 6, 8, 12; and also by those composed of three of them, that is, by 12, 16, 24; and, lastly, by 48 itself. From this it follows, that when a number has been represented by its factor it is easy to find all the numbers by which it is divisible.

548. It is necessary to observe, that every number is divisible by 1 and by itself, so that there is no number that has not at least two factors or divisors, the number itself and unity; but if a number have no other than these two it belongs to the class of numbers called prime numbers. With the exception of those, all numbers have other divisor besides unity and themselves, as may be seen from the subjoined table, wherein all its divisors are placed under each number, and the prime numbers marked with a P.

Numbers - - -	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20
Divisors - - -	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
		2	3	2	5	2	7	2	3	2	11	2	13	2	3	2	17	2	19	2
				4		3		4	9	5		3		7	5	4		3		4
						6		8		10		4		14	15	8		6		5
Number of divisors -												6				16			10	
												12						18		20
	1	2	2	3	2	4	2	4	3	4	2	6	2	4	4	5	2	6	2	6
	P	P	P		P		P				P		P				P		P	

We must here observe, that 0, or nothing, may be considered a number having the property of being divisible by all possible numbers, because by whatever number  $a0$  is divided, the quotient must be 0; for the multiplication of any number by nothing produces nothing, hence  $0a$  is 0.

## FRACTIONS.

549. When a number is said not to be divisible by another number, it only means that the quotient cannot be expressed by an integer number. For if we imagine a line of 7 feet in length, it is impossible to doubt that it may be divided into three equal parts, of the length of each whereof a notion may be formed. But as the quotient of 7 divided by 3 is not an integer number, we are thus led to the consideration of a particular species of numbers called *fractions* or *broken numbers*. If we have to divide 7 by 3 the quotient may be conceived and expressed by  $\frac{7}{3}$ , placing the divisor under the dividend, and separating them by a stroke or line.

550. Generally, moreover, if the number  $a$  is to be divided by the number  $b$ , the quotient is  $\frac{a}{b}$ , and this form of expression is called a fraction. In all fractions the lower number is called the *denominator*, and that above the line the *numerator*. In the above fraction of  $\frac{7}{3}$ , which is read *seven thirds*, 7 is the numerator and 3 the denominator. In reading fractions we call  $\frac{4}{5}$  four fifths,  $\frac{7}{8}$  seven eighths,  $\frac{15}{100}$  fifteen hundredths, and  $\frac{1}{2}$  one half.

551. In order to become thoroughly acquainted with the nature of fractions it is proper to begin by considering the case of the numerator being equal to the denominator as  $\frac{a}{a}$ . Now as this is a representation of the quotient obtained by dividing  $a$  by  $a$ , it is evident it is once contained in it, that is, the quotient is exactly unity, hence  $\frac{a}{a}$  is equal to 1; and for the same reason all the following fractions,  $\frac{2}{2}$ ,  $\frac{3}{3}$ ,  $\frac{4}{4}$ ,  $\frac{5}{5}$ ,  $\frac{6}{6}$ ,  $\frac{7}{7}$ , &c., are equal to one another, each being equal to unity. It is evident, then, that fractions whose numerators are less than the denominators have a value less than unity, for if a number be divided by another which is greater, the result must necessarily be less than 1. Thus, if a line two feet long be cut into three parts, two of them will undoubtedly be shorter than a foot; it is evident, then, that  $\frac{2}{3}$  is less than 1, for the same reason that the numerator 2 is less than the denominator 3.

552. But if, on the contrary, the numerator be greater than the denominator, the value of the fraction is greater than unity. Thus  $\frac{4}{3}$  is greater than 1, for  $\frac{4}{3}$  is equal to  $\frac{3}{3}$  together with  $\frac{1}{3}$ . Now  $\frac{4}{3}$  is exactly 1, consequently  $\frac{4}{3}$  is equal to  $1 + \frac{1}{3}$ , that is, to an integer and a third. So  $\frac{5}{4}$  is equal to  $1\frac{1}{4}$ , or  $1\frac{1}{4}$ ;  $\frac{7}{4}$  is equal to  $1\frac{3}{4}$ ; and  $\frac{12}{5}$  is equal to  $2\frac{2}{5}$ . Generally, if we divide the upper member by the lower, and add to the quotient a fraction whose numerator expresses the remainder and the divisor the denominator, we shall in other terms represent the fraction. For example, in the fraction  $\frac{69}{19}$  the quotient is 3 and the remainder 3, hence  $\frac{69}{19}$  is the same as  $3\frac{3}{19}$ .

553. Fractions, then, whose numerators are greater than their denominators, consist of two numbers; one of which is an integer, and the other a fractional number, in which the numerator is less than the denominator; and when fractions contain one or more integers, they are called *improper fractions*, to distinguish them from fractions properly so called, in which the numerator is less than the denominator, whence they are less than unity, or than an integer. There is another way of considering fractions, which may illustrate the sub-

ject. Thus, in the fraction  $\frac{5}{10}$  it is evident that it is five times greater than  $\frac{1}{10}$ . This last fraction expresses one of the 10 parts into which 1 may be divided, and that in taking five of those parts we have the value of the fraction  $\frac{5}{10}$ .

554. It is from this mode of considering a fraction that the terms *numerator* and *denominator* are derived; that is to say, the lower number expresses or *denotes* the number of parts into which the integer is divided, and is therefore called the *denominator*, the upper number, or that above the line *numbers* the quantity of those parts, and is thence called the *numerator*. It follows, then, that as the denominator is increased the smaller the parts become, as in  $\frac{1}{2}$ ,  $\frac{1}{3}$ ,  $\frac{1}{4}$ ,  $\frac{1}{5}$ ,  $\frac{1}{6}$ , and so on; and it is evident that if the integer be divided into two parts, each of those parts is greater than if it had been divided into eight. In this division of the integer it is impossible to increase the denominator so that the fraction shall be reduced to nothing; for into whatever number of parts unity may be divided, however small they be, they still preserve some definite magnitude. Indeed, to whatever extent we continue the series of fractions just named, they will always represent a certain quantity. From this has arisen the expression that the denominator must be infinitely great, or *infinite*, to reduce the fraction to 0, or nothing, which in this case means nothing more than that it is impossible to reach the end of the series of the fractions in question. This idea is expressed by the use of the sign  $\infty$ , which indicates a number infinitely great, and we may therefore say that  $\frac{1}{\infty}$  is really nothing, because a fraction can only be lessened to nothing when the denominator has been increased to infinity. This, moreover, leads us to another view of the matter, which is important. The fraction,  $\frac{1}{\infty}$ , as we have seen, represents the quotient resulting from the division of 1 by  $\infty$ . Now, if 1 be divided by  $\frac{1}{\infty}$  or 0, the quotient will be again  $\infty$ , and a new idea of infinity is thus obtained, arising from the division of 1 by 0; and thus we are justified in saying that 1 divided by 0 expresses  $\infty$ , or a number infinitely great. From this, moreover, we learn that a number infinitely great is susceptible of increase, for having seen that  $\frac{1}{b}$  denotes a number infinitely great,  $\frac{2}{b}$ , the double of it, must be greater, and so on.

# PROPERTIES OF FRACTIONS.

555. It has been seen that  $\frac{2}{2}$ ,  $\frac{3}{3}$ ,  $\frac{4}{4}$ ,  $\frac{5}{5}$ , &c. are equal to 1, and thence equal to one another; the same equality obtains in the fractions  $\frac{2}{4}$ ,  $\frac{3}{6}$ ,  $\frac{4}{8}$ , &c., which, from what has been said, it is obvious are each equal to  $\frac{1}{2}$ , and to one another, so the fractions  $\frac{2}{3}$ ,  $\frac{4}{6}$ ,  $\frac{8}{12}$  are, from their common value, being  $\frac{2}{3}$  each, equal to one another. In the same way, a fraction may be represented in an infinity of ways by multiplying the numerator and denominator by the same number, be that number what it may; thus,  $\frac{1}{2}$ ,  $\frac{2}{4}$ ,  $\frac{3}{6}$ ,  $\frac{4}{8}$ ,  $\frac{5}{10}$ , &c. are equal, the common value being  $\frac{1}{2}$ . So, to give another example,  $\frac{1}{3}$ ,  $\frac{2}{6}$ ,  $\frac{3}{9}$ ,  $\frac{4}{12}$ , &c. are all equal to  $\frac{1}{3}$ . Hence, we arrive at the general conclusion that the fraction  $\frac{a}{b}$  may be equally represented by the following expressions, each equal to  $\frac{a}{b}$  viz.  $\frac{a}{b}$ ,  $\frac{2a}{2b}$ ,  $\frac{3a}{3b}$ ,  $\frac{4a}{4b}$ , &c. That this is the case we

may see by substituting a certain letter  $c$  for the fraction  $\frac{a}{b}$ , which letter we will consider as representing the quotient of  $a$  divided by  $b$ ; recollecting, then, that the multiplication of the quotient  $c$  by the divisor  $b$  must give the dividend; for by the hypothesis, as  $c$  multiplied by  $b$  gives  $a$ , it is evident that  $c$  multiplied by  $2b$  must give  $2a$ , that  $c$  multiplied by  $3b$  will give  $3a$ ; and that in general  $c$  multiplied by  $mb$  ( $m$  representing any given number) must give  $ma$ . The converse brings us to the division of  $a$  by  $b$ , in which, if we divide the product  $ma$  by  $mb$  one of the factors, the quotient is equal to  $c$ , the other factor. But  $ma$  divided by  $mb$  gives also the fraction  $\frac{ma}{mb}$ , which is therefore equal to  $c$ , which was the matter to be proved; for  $c$  was assumed as the value of the fraction  $\frac{a}{b}$ , and hence this fraction is equal to the fraction  $\frac{ma}{mb}$ , whatever the value of  $m$ .

556. The infinite forms in which fractions may be represented, so as to express the same value, has been before shown; and it is obvious, that of those forms, that which is given in the smallest numbers is more immediately understood. Thus the fraction  $\frac{1}{4}$  or one quarter, is more easily comprehended than  $\frac{4}{16}$ ,  $\frac{5}{20}$ ,  $\frac{6}{24}$ ,  $\frac{7}{28}$ , &c. It therefore becomes a matter of convenience to express a fraction in the least possible numbers, or in its least terms. This is a problem not difficult of resolution when we recollect that all fractions retain their value if the numerator and denominator are multiplied by the same number, from which we also learn that if they are divided by the same number their value is not altered. As an example in the general expression  $\frac{ma}{mb}$ , if both numerator and denominator be divided by the number  $m$ , we obtain the fraction  $\frac{a}{b}$ , which has before been seen to be equal to  $\frac{ma}{mb}$ .

557. From the above, then, it is evident that to reduce a fraction to its least terms, we

have only to find a number which will divide the numerator and denominator, and this number is called a *common divisor*, which if we can find, the fraction may be reduced to a lower form; but if we cannot find such a number, and unity is the only common divisor that can be found, the fraction is already in its simplest form. Thus, taking the fraction  $\frac{96}{360}$ , we may immediately perceive that 2 will divide both the terms, whereof the result is  $\frac{48}{180}$ ; this result is again divisible by 2, by which the fraction is reduced to  $\frac{24}{90}$ , in which we again find 2 as a common divisor, and the result of that is  $\frac{12}{45}$ . In this we may perceive that, as 2 will no longer divide the terms, another number must be sought, and by trial that number will be seen to be 3, by using which we obtain the fraction  $\frac{4}{15}$ , the simplest expression to which it can be reduced, for 1 is the only common divisor of the numbers 4 and 15, and division by unity will not reduce those numbers. This property of the invariable value of fractions leads to the conclusion that in the addition and subtraction of them, the operations are performed with difficulty, unless they are reduced to expressions wherein the denominators are equal. And here it will be useful to observe that all integers are capable of being represented by fractions; for it is manifest that 9 and  $\frac{9}{1}$  are the same, 9 divided by 1 giving a quotient of 9; which last number may also be equally represented by  $\frac{18}{2}$ ,  $\frac{36}{4}$ ,  $\frac{72}{8}$ ,  $\frac{144}{16}$ , &c. &c.

#### ADDITION AND SUBTRACTION OF FRACTIONS.

558. When the denominators of fractions are equal they are easily added to and subtracted from one another: thus,  $\frac{3}{8} + \frac{5}{8}$  is equal to  $\frac{8}{8}$  or 1, and  $\frac{5}{8} - \frac{3}{8}$  is equal to  $\frac{2}{8}$  or  $\frac{1}{4}$ . In this case, either for addition or subtraction, it is only necessary to change the numerators and place the common denominator under the result, thus:—

$$\begin{aligned}\frac{3}{11} - \frac{2}{11} + \frac{5}{11} - \frac{4}{11} &= \frac{7}{11} \text{ or } \frac{1}{2} \\ \frac{9}{13} - \frac{4}{13} - \frac{1}{13} + \frac{2}{13} &= \frac{6}{13} \\ \frac{1}{4} + \frac{6}{4} &= \frac{7}{4} \text{ or } 1 \\ \frac{3}{5} - \frac{4}{5} + \frac{1}{5} &= \frac{0}{5} \text{ or nothing.}\end{aligned}$$

If fractions have not the same denominator, they must, for the purpose in question, be changed into others that are in that condition. For an example, let us take the fractions  $\frac{1}{2}$  and  $\frac{1}{3}$ ; it is evident that  $\frac{1}{2}$  is the same as  $\frac{3}{6}$ , and that  $\frac{1}{3}$  is equivalent to  $\frac{2}{6}$ ; the fractions for adding together therefore become  $\frac{3}{6} + \frac{2}{6}$ , whose sum is  $\frac{5}{6}$ . If the latter is to be subtracted from the former, or, in other words, to be united by the sign  $-$ , as  $\frac{1}{2} - \frac{1}{3}$ , we shall have  $\frac{3}{6} - \frac{2}{6}$ , or  $\frac{1}{6}$ .

559. It often becomes necessary to reduce a number of fractions to a common denominator: thus, suppose we have the fractions  $\frac{1}{2}$ ,  $\frac{2}{3}$ ,  $\frac{3}{4}$ ,  $\frac{4}{5}$ . We have here only to find a number divisible by all the denominators of those fractions. In the above case, that number will, by trial, be seen to be 60, which therefore will be the common denominator. Substituting this, we shall have  $\frac{30}{60}$  instead of  $\frac{1}{2}$ ;  $\frac{40}{60}$  instead of  $\frac{2}{3}$ ;  $\frac{45}{60}$  instead of  $\frac{3}{4}$ ;  $\frac{48}{60}$  instead of  $\frac{4}{5}$ ; and  $\frac{50}{60}$  instead of  $\frac{5}{6}$ . The addition of all these fractions thus becomes simple enough, for we have only to add the numerators together, and place under that sum the common denominator, that is to say, we shall have  $\frac{213}{60}$ , which is equal to  $3\frac{33}{60}$  or  $3\frac{11}{20}$ . Thus, all that is necessary is to change two fractions whose denominators are unequal into two others whose denominators are equal. For the performance of this generally, if  $\frac{a}{d}$  and  $\frac{c}{b}$  be the fractions, first multiply both the terms of the first fraction by  $d$ , and we shall have  $\frac{ad}{bd}$  equal to  $\frac{c}{b}$ ; then multiply both the terms of the second fractions by  $b$ , and we have its equivalent value in  $\frac{bc}{bd}$  whereby also the two denominators are become equal. The sum of these fractions is now readily obtained, being  $\frac{ad+bc}{bd}$ , and their difference is evidently  $\frac{ad-bc}{bd}$ . Suppose the fractions  $\frac{2}{3}$  and  $\frac{1}{4}$  proposed, we have in their stead  $\frac{40}{60}$  and  $\frac{15}{60}$ , whereof the sum is  $\frac{55}{60}$ , and the difference  $\frac{25}{60}$ . It is by the method just mentioned that we are enabled to ascertain which is the greater and which the less; thus, in the two fractions  $\frac{2}{3}$  and  $\frac{1}{4}$ , it is evident that the last is smaller than the first, for, reduced to the same denominator, the first is  $\frac{40}{60}$ , and the second  $\frac{15}{60}$ , whence it is evident that  $\frac{1}{4}$  is less than  $\frac{2}{3}$  by  $\frac{25}{60}$ .

560. To subtract a fraction from an integer, it is only necessary to change one of its units into a fraction having the same denominator as that which is to be subtracted: thus to subtract  $\frac{2}{3}$  from 1 we write  $\frac{3}{3}$  instead of 1, from which if  $\frac{2}{3}$  be taken  $\frac{1}{3}$  remain. Again, suppose  $\frac{2}{3}$  is to be subtracted from 2, we may either write  $\frac{4}{2}$  or  $1\frac{1}{2}$ , from which  $\frac{2}{3}$  subtracted leave  $\frac{5}{6}$  or  $1\frac{1}{2}$ . It is only necessary to divide the numerator by the denominator, to see how many integers it contains. We have nearly the same operation to perform in adding numbers composed of integers and fractions; thus, let it be proposed to add  $5\frac{1}{2}$  to  $3\frac{1}{3}$ , then taking  $\frac{1}{2}$  and  $\frac{1}{3}$  or, which is the same,  $\frac{3}{6}$  and  $\frac{2}{6}$  their sum is  $\frac{5}{6}$ ; the sum total, therefore, will be  $8\frac{5}{6}$ .

MULTIPLICATION AND DIVISION OF FRACTIONS.

561. For the multiplication of a fraction by an integer, or whole number, the rule is to multiply the numerator only by the given number, the denominator remaining unchanged : thus —

- 2 times or twice  $\frac{1}{2}$  makes  $\frac{2}{2}$  or 1 integer,
- 2 times or twice  $\frac{1}{3}$  makes  $\frac{2}{3}$ ,
- 3 times or thrice  $\frac{1}{3}$  makes  $\frac{3}{3}$  or  $\frac{1}{1}$ ,
- 4 times  $\frac{1}{12}$  makes  $\frac{4}{12}$  or  $1\frac{1}{3}$  or  $1\frac{2}{3}$ .

But when it can be done, it is preferable to divide the denominator by the integer, inasmuch as the operation is shortened by it ; for example, in multiplying  $\frac{2}{3}$  by 3, by the rule above given, we have  $\frac{2 \times 3}{3}$ , which is reduced then to  $\frac{6}{3}$ , and, lastly, to  $2\frac{0}{3}$ . But if the numerator remain and the denominator is divided by the integer, we have at once  $\frac{2}{1}$  or  $2\frac{0}{1}$  for the product sought. Likewise  $\frac{1}{12}$  multiplied by 5 gives  $\frac{5}{12}$  or  $3\frac{1}{4}$ , that is  $3\frac{1}{4}$ .

562. Generally, then, the product of the multiplication of a fraction  $\frac{a}{b}$  by  $c$  is  $\frac{ac}{b}$ , and it is to be observed that when the integer is exactly equal to the denominator, the product must be equal to the numerator. So that —

- $\frac{1}{2}$  taken twice gives 1,
- $\frac{2}{3}$  taken thrice gives 2,
- $\frac{3}{4}$  taken 4 times gives 3.

and, generally, if the fraction  $\frac{a}{b}$  be multiplied by the number  $b$ , the product, as has already been seen, must be  $a$ , for as  $\frac{a}{b}$  represents a quotient resulting from the division of the dividend  $a$  by the divisor  $b$ , and since we have seen that the quotient multiplied by the divisor will give the dividend, it is evident that  $\frac{a}{b}$  multiplied by  $b$  must produce  $a$ . We are next to consider how a fraction can be divided by an integer before proceeding to the multiplication of fractions by fractions. It is evident, if I have to divide the fraction  $\frac{2}{3}$  by 3, the result is  $\frac{2}{9}$ , and that the quotient of  $\frac{2}{3}$  divided by 4 is  $\frac{1}{6}$  : the rule is therefore to divide the numerator by the integer, and leave the denominator unchanged. Thus —

- $\frac{1}{3}$  divided by 2 gives  $\frac{1}{6}$ ,
- $\frac{1}{3}$  divided by 7 gives  $\frac{1}{21}$ , &c. &c.

563. The rule is easily applied if the numerator be divisible by the number proposed ; as this is not always the case, it is to be observed that a fraction may be transformed into an infinite number of similar expressions, in some of which the numerator might be divided by the given integer. Thus, for example, to divide  $\frac{2}{3}$  by 2, we may change the fraction into  $\frac{4}{6}$ , in which the numerator may be divided by 2, and the quotient is therefore  $\frac{2}{6}$ .

564. In general, to divide the fraction  $\frac{a}{b}$  by  $c$ , it is changed into  $\frac{ac}{bc}$ , and then dividing the numerator  $ac$  by  $c$ , write  $\frac{a}{bc}$  for the quotient sought.

565. Hence, when a fraction  $\frac{a}{b}$  is to be divided by an integer  $c$ , it is necessary merely to multiply the denominator by that number, leaving the numerator as it is. Thus,  $\frac{5}{6}$  divided by 3 gives  $\frac{5}{18}$ , and  $\frac{7}{8}$  divided by 6 gives  $\frac{7}{48}$ . When, however, the numerator is divisible by the integer, the operation is still simpler. Thus,  $\frac{9}{10}$  divided by 3 would give according to the first given rule  $\frac{3}{10}$ , but by this last rule we at once obtain  $\frac{3}{10}$ , an expression equivalent to, but more simple than,  $\frac{9}{30}$ .

566. We now perceive, then, in what way one fraction  $\frac{a}{b}$  may be multiplied by another  $\frac{c}{d}$ . Here  $\frac{c}{d}$  means that  $c$  is to be divided by  $d$ , and on this principle we must first multiply  $\frac{a}{b}$  by  $c$ , the result whereof is  $\frac{ac}{b}$ , after which we divide by  $d$ , which gives  $\frac{ac}{bd}$ . From this arises the rule for multiplying fractions, which is, to multiply the numerators and denominators separately. Thus —

- $\frac{1}{2}$  multiplied by  $\frac{1}{6}$  gives the product  $\frac{1}{12}$ ,
- $\frac{2}{3}$  multiplied by  $\frac{1}{12}$  produces  $\frac{2}{36}$ ,
- $\frac{3}{4}$  multiplied by  $\frac{1}{10}$  produces  $\frac{3}{40}$ , &c. &c.

567. We are now to see how one fraction may be divided by another. And, first, it is to be observed, that if the two fractions have similar denominators, the division is performed only with respect to the numerators, for it is manifest that  $\frac{3}{12}$  are as many times contained in  $\frac{9}{12}$  as 3 in 9, that is, three times ; and in the same manner in order to divide  $\frac{7}{10}$  by  $\frac{9}{10}$ , we have only to divide 7 by 9 which is  $\frac{7}{9}$ . So we shall have  $\frac{6}{20}$  in  $\frac{18}{20}$  3 times,  $\frac{10}{100}$  in  $\frac{40}{100}$  4 times.

568. If the denominators of the fractions are not equal, they must, by the method before given, be reduced to a common denominator. Thus, if the fraction  $\frac{a}{b}$  is to be divided by  $\frac{c}{d}$ , we have  $\frac{ad}{bd}$  to be divided by  $\frac{bc}{db}$ ; whence it becomes evident that the quotient will be represented simply by the division of  $ad$  by  $bc$  or  $\frac{ad}{bc}$ . Hence the following rule: multiply the numerator of the dividend by the denominator of the divisor, and the denominator of the dividend by the numerator of the divisor, the first product will be the numerator of the quotient and the second its denominator.

569. If this rule be applied to the division of  $\frac{3}{4}$  by  $\frac{7}{8}$  we have  $\frac{24}{32}$  or  $1\frac{1}{8}$ , and  $\frac{28}{32}$  by  $\frac{5}{8}$  gives  $\frac{140}{256}$  or  $\frac{35}{64}$ .

570. There is a rule which operates the same results, and is more easily recollected; it is, to invert the fraction which is the divisor, that is, place the denominator for the numerator and the numerator for the denominator; then multiply the numerators together for a new numerator, and the denominators for a new denominator, and the product will be the quotient sought. Thus,  $\frac{1}{4}$  divided by  $\frac{3}{8}$  is the same as  $\frac{1}{4}$  multiplied by  $\frac{8}{3}$ , which make  $\frac{8}{12}$ . Also  $\frac{5}{8}$  divided by  $\frac{3}{8}$  is the same as  $\frac{5}{8}$  multiplied by  $\frac{8}{3}$ , which is  $\frac{40}{24}$ ; that is, in general terms, to divide by the fraction  $\frac{1}{2}$  is the same as to multiply by  $\frac{2}{1}$  or 2, that division by  $\frac{1}{4}$  is the same as multiplication by  $\frac{4}{1}$  or by 4.

571. Thus, the number 100 divided by  $\frac{1}{2}$  is 200, and 1000 divided by  $\frac{1}{3}$  will give 3000. So also if 1 be divided by  $\frac{1}{1000}$  the quotient would be 1000; and 1 divided by  $\frac{1}{100000}$  gives 100,000. This view is useful in enabling us to conceive that, when any number is divided by 0, the result must be a number infinitely great; for the division of 1 by the small fraction  $\frac{1}{1000000}$  gives for a quotient 1,000,000,000.

572. As every number, when divided by itself, produces unity, a fraction divided by itself must also give 1 for a quotient. For to divide  $\frac{3}{4}$  by  $\frac{3}{4}$ , we must, by the rule, multiply  $\frac{3}{4}$  by  $\frac{4}{3}$ , by which we obtain  $\frac{12}{12}$ , or 1; and if it be required to divide  $\frac{a}{b}$  by  $\frac{a}{b}$ , we multiply  $\frac{a}{b}$  by  $\frac{b}{a}$ ; now the product  $\frac{ab}{ab}$  is equal to 1.

573. There remains to explain an expression in frequent use, — such, for instance, as the half of  $\frac{3}{10}$ : this signifies that we must multiply  $\frac{1}{10}$  by  $\frac{3}{2}$ , which is  $\frac{3}{20}$ . So, if it be required to know the value of  $\frac{1}{10}$  of  $\frac{3}{4}$ , they are to be multiplied together, which produces  $\frac{3}{40}$ ; and  $\frac{3}{4}$  of  $\frac{3}{10}$  is the same as  $\frac{9}{10}$  multiplied by  $\frac{3}{4}$ , which produces  $\frac{27}{40}$ .

574. We have, in a previous section, laid down for integers the signs of + and −, and the same rule holds with regard to fractions. Thus  $+\frac{1}{2}$  multiplied by  $-\frac{1}{3}$  makes  $-\frac{1}{6}$ ; and  $-\frac{2}{3}$  multiplied by  $-\frac{4}{5}$  gives  $+\frac{8}{15}$ . Further,  $-\frac{1}{4}$  divided by  $+\frac{2}{3}$  makes  $-\frac{3}{8}$ , or  $-1\frac{1}{8}$ ; and  $-\frac{1}{4}$  divided by  $-\frac{1}{4}$  makes  $+\frac{28}{28}$ , or  $3\frac{1}{4}$ , that is,  $3\frac{1}{4}$ .

#### SQUARE NUMBERS.

575. If a number be multiplied by itself, the product is called a *square*, in relation to which the number itself is called a *square root*. Thus, if we multiply 12 by 12, the product 144 is a square whose root is 12. The origin of this term is borrowed from geometry, by which we learn that the contents of a square are found by multiplying its side by itself.

576. Square numbers, therefore, are found by multiplying the root by itself. Thus, 1 is the square of 1; since 1 multiplied by 1 makes 1. So 25 is the square of 5, and 64 the square of 8. 7, also, is the root of 49, and 9 is the root of 81. Beginning with the squares of natural numbers, we subjoin a small table, in the first line whereof the roots or numbers are ranged, and on the second their squares.

Numbers . . .	1	2	3	4	5	6	7	8	9	10	11	12	13
Squares . . .	1	4	9	16	25	36	49	64	81	100	121	144	169

577. A singular property will be immediately perceived in this table, which is, that in the series of square numbers, if the preceding one be subtracted from that following, the remainders always increase by 2, forming the following series, —

3, 5, 7, 9, 11, 13, 15, 17, 19, 21, &c.,

which is that of the odd numbers.

578. The squares of fractions are found in the same manner as those of whole numbers, that is, by multiplying any given fraction by itself; thus the square of  $\frac{1}{2}$  is  $\frac{1}{4}$ .

$$\text{The square of } \left\{ \begin{array}{c} \frac{1}{2} \\ \frac{3}{8} \\ \frac{4}{9} \\ \frac{5}{12} \end{array} \right\} \text{ is } \left\{ \begin{array}{c} \frac{1}{4} \\ \frac{9}{64} \\ \frac{16}{81} \\ \frac{25}{144} \end{array} \right\}$$

Hence we have only to divide the square of the numerator by that of the denominator, and the fraction expressing that division is the square of the given fraction. Thus  $\frac{49}{81}$  is the square of  $\frac{7}{9}$ , and, reciprocally,  $\frac{9}{7}$  is the root of  $\frac{49}{81}$ .

579. If the square of a mixed number, or one that is composed of an integer and a fraction, be sought, no more is necessary than to reduce it to a single fraction, and then take the square of that fraction. Thus, to find the square of  $2\frac{1}{4}$ , it must first be expressed by the fraction  $\frac{9}{4}$ ; and, taking its square, we have  $\frac{81}{16}$ , or  $5\frac{1}{16}$  for the value of the square of  $2\frac{1}{4}$ . And so of any similar numbers. The squares of the numbers between 3 and 4, supposing them to increase by one fourth, are as follow : —

Numbers . .	3	$3\frac{1}{4}$	$3\frac{1}{2}$	$3\frac{3}{4}$	4
Squares . .	9	$10\frac{9}{16}$	$12\frac{1}{4}$	$14\frac{1}{16}$	16

From this small tabular view it may be inferred that if a root contain a fraction, its square also contains one. Thus, let the root be  $1\frac{3}{16}$ , its square is  $\frac{441}{256}$ , or  $1\frac{171}{256}$ , that is, rather more than half as great again as the integer 1.

580. Generally, when the root is  $a$  the square must be  $aa$ ; if the root be  $2a$  the square will be  $4aa$ ; from which it is evident that by doubling the root the square becomes 4 times greater; for if the root be  $4a$ , the square is  $16aa$ . If the root be  $ab$ , the square is  $aabb$ ; if  $abc$ , the square is  $aabccb$ .

581. Thus, then, if the root be composed of more factors than one, their squares must be multiplied together; and, reciprocally, if a square be composed of more than one factor whereof each is a square, it is only necessary to multiply the roots of these squares to obtain the complete square of the root proposed. Thus, as 5184 is equal to  $9 \times 16 \times 36$ , the square root of it is  $3 \times 4 \times 6$ , or 72; and 72, it will be seen, is the true square root of 5184; for  $72 \times 72$  gives 5184.

582. Here we must for a moment stop to see how the signs + and - affect our operations: and, first, it cannot be doubted that if the root is a positive quantity, that is, with the sign + before it, its square must be a positive quantity; for + by + makes +: thus, the square of + $a$  will be + $aa$ . So, also, if the root be a negative number, as - $a$ , the square will still be positive, for it is + $aa$ ; from which it follows that of + $a$ , as well as - $a$ , the square is + $aa$ ; hence every square has two roots, one positive and the other negative. For example, the square of 16 is both +4 and -4, because -4 multiplied by -4 gives 16, as well as +4 by +4.

#### SQUARE ROOTS, AND THE IRRATIONAL NUMBERS THAT RESULT FROM THEM.

583. In the last section it has been seen that the square root of any number is but one whose square is equal to the given number, and that to those roots the positive or negative sign may be prefixed; so that if we could remember a sufficient number of squares, their roots would at the same time present themselves to our mind. Thus, if 144 were the given number, we should at once recollect that its square root is 12.

584. For the same reason fractions would be easily managed; for we at once see that  $\frac{4}{9}$  is the square root of  $\frac{16}{81}$ , inasmuch as we have only to take the square root of the numerator and that of the denominator to be convinced of it.

If we have to deal with a mixed number, we have only to put it in the shape of a single fraction: for example,  $12\frac{1}{4}$  is equivalent to  $\frac{49}{4}$ ; and we see by inspection that  $\frac{7}{2}$  or  $3\frac{1}{2}$  must be the square root of  $12\frac{1}{4}$ . But when the given number is not a square, as, for example, 12, it is not possible to extract its square root, that is, to find a number multiplied by itself whose product is 12. It is, however, clear that the square root of 12 is greater than 3; for  $3 \times 3$  produces only 9; and it must be less than 4, because  $4 \times 4$  produces 16, which is greater than 12. From the table just given we may see that the square of  $3\frac{1}{2}$  or  $\frac{7}{2}$  is  $12\frac{1}{4}$ ; hence the root must be less than  $3\frac{1}{2}$ . We may, however, come nearer to this root by comparing it with  $3\frac{7}{13}$ ; for the square of  $3\frac{7}{13}$ , or of  $\frac{52}{13}$ , is  $\frac{2704}{169}$ , or  $12\frac{4}{13}$ , a fraction only greater by  $\frac{1}{13}$  than the root required. Now, as  $3\frac{1}{2}$  and  $3\frac{7}{13}$  are both greater than the root of 12, it might be possible to add to 3 a fraction a little less than  $\frac{7}{13}$ , precisely such that the square of such sum should be exactly equal to 12. Trying, therefore, with  $3\frac{3}{7}$ ,  $\frac{3}{7}$  being a little less than  $\frac{7}{13}$ , we have  $3\frac{3}{7}$  equal to  $\frac{24}{7}$ , whose square is  $\frac{576}{49}$ , and consequently less than 12 by  $\frac{48}{49}$ ; because 12 may be expressed by  $\frac{588}{49}$ . Hence we perceive that  $3\frac{3}{7}$  is less and  $3\frac{7}{13}$  is greater than the root required. Trying a number,  $3\frac{5}{17}$ , which is a little greater than  $3\frac{3}{7}$ , but less than  $3\frac{7}{13}$ , its equivalent is  $\frac{38}{17}$ , and it will have for its square  $\frac{1444}{289}$ ; and as 12 reduced to the same denominator is  $\frac{1428}{289}$ , we thus find that  $3\frac{5}{17}$  is as yet less by  $\frac{8}{121}$  than the root of 12. If for  $\frac{5}{17}$  the fraction  $\frac{6}{13}$ , which is a little greater, be substituted, we have the square of  $3\frac{6}{13}$  equal to  $\frac{2025}{169}$ ; and 12 reduced to the same denominator, or multiplied by 169, equal to  $\frac{2029}{169}$ ; so that  $3\frac{6}{13}$  is yet too small, though only by  $\frac{4}{169}$ , whilst  $3\frac{7}{13}$  has been found too great. From this it is evident that whatever fraction be joined to 3, the

square of that sum will always contain a fraction, and will not be equal exactly to the integer 12. For, knowing that the square root of 12 is greater than  $3\frac{2}{3}$ , and less than  $3\frac{7}{10}$ , we are nevertheless unable to assign between the two an intermediate fraction, which, added to 3, precisely expresses the square root of 12. But it must not therefore be said that the square root of 12 cannot be absolutely determined, but only that it cannot be expressed by fractions.

585. We hence find that there exists a species of numbers which, though not expressible by fractions, are yet determinate quantities, and of this the square root of 12 furnishes an example. This species of numbers are termed *irrational numbers*, and occur as often as we attempt to find the square root of a number which is not a square. Thus, 2 not being a perfect square, its square root, or the number which, multiplied by itself, would produce 2, is an irrational quantity. Such numbers are also called *surd quantities*, or *incommensurables*; and though they cannot be expressed by fractions, they are, nevertheless, magnitudes of which an accurate idea may be formed. In the case of the number 12, for example, though its square root is not apparent, we know that it is a number which, multiplied by itself, would exactly produce 12; and this is a property which, by the power of approximating to it, is enough to enable us to form some idea of it.

586. Having now obtained a distinct idea of the nature of these irrational numbers, we must introduce to the reader the use of the sign  $\sqrt{\phantom{x}}$  (square root), which is used to express the square roots of all numbers that are not perfect squares. Thus  $\sqrt{12}$  signifies or represents the square root of 12, or that number which, multiplied by itself, produces 12. So  $\sqrt{2}$  represents the square root of 2,  $\sqrt{\frac{2}{3}}$  that of  $\frac{2}{3}$ , and, generally,  $\sqrt{a}$  represents the square root of the number  $a$ . If, therefore, we have at any time to express the square root of a number, all that is necessary is, to prefix to it the sign  $\sqrt{\phantom{x}}$ . This explanation of irrational numbers enables us to apply to them the known methods of calculation. For, inasmuch as the square root of 2 multiplied by itself must produce 2, we know that  $\sqrt{2} \times \sqrt{2}$  will produce 2, and that  $\sqrt{\frac{2}{3}} \times \sqrt{\frac{2}{3}}$  makes  $\frac{2}{3}$ ; and so of any other number, and, generally, that  $\sqrt{a} \times \sqrt{a}$  produces  $a$ .

587. When, however, it is required to multiply  $\sqrt{a}$  by  $\sqrt{b}$ , the product is  $\sqrt{ab}$ , for it has been heretofore shown that when a square has two or more factors, its root is composed of the roots of those factors. Hence we find the square root of the product  $ab$ , which is  $\sqrt{ab}$ , by multiplying the square root of  $a$ , or  $\sqrt{a}$ , by the square root of  $b$ , or  $\sqrt{b}$ . And from this it is evident that if  $b$  were equal to  $a$ ,  $\sqrt{aa}$  would be the product of  $\sqrt{a}$  by  $\sqrt{b}$ . Now, there can be no doubt that  $\sqrt{aa}$  must be  $a$ , for  $aa$  is the square of  $a$ .

588. In division, if it be required to divide  $\sqrt{a}$  by  $\sqrt{b}$ , the quotient must be  $\sqrt{\frac{a}{b}}$ , in which it may be, that the irrational number may vanish in the quotient. Thus, in the case of dividing  $\sqrt{18}$  by  $\sqrt{8}$ , the quotient is  $\sqrt{\frac{18}{8}}$ , which is reduced to  $\sqrt{\frac{9}{4}}$ , and, consequently, to  $\frac{3}{2}$ ,  $\frac{9}{4}$  being the square of  $\frac{3}{2}$ .

589. When the number to which the radical sign  $\sqrt{\phantom{x}}$  is prefixed happens to be a square, the expression of the root follows the ordinary course. Thus,  $\sqrt{4}$  is equivalent to 2;  $\sqrt{9}$  is the same as 3;  $\sqrt{81}$  the same as 9; and  $12\frac{1}{4}$  the same as  $\frac{5}{2}$  or  $3\frac{1}{4}$ ; in which instances the irrationality is but apparent, and vanishes.

590. No difficulty occurs in multiplying irrational by ordinary numbers. Thus 2 multiplied by  $\sqrt{5}$  produces  $2\sqrt{5}$ , and 3 multiplied by  $\sqrt{2}$  produces  $3\sqrt{2}$ . In the last instance, however, as 3 is equal to  $\sqrt{9}$ , the expression is also 3 times  $\sqrt{2}$  by  $\sqrt{9}$  multiplied by  $\sqrt{2}$  or by  $\sqrt{18}$ . In the same way of considering this matter,  $2\sqrt{a}$  is the same as  $\sqrt{4a}$ , and  $3\sqrt{a}$  is equivalent to  $\sqrt{9a}$ . Generally,  $b\sqrt{a}$  is equivalent to the square root of  $bba$  or  $\sqrt{abb}$ ; and, reciprocally, when the number preceded by the radical sign contains a square, the root of the square may be prefixed to the sign, as in writing  $b\sqrt{a}$  instead of  $\sqrt{bba}$ . From this it will be easy to comprehend the following expressions:—

$$\left. \begin{array}{l} \sqrt{8} \text{ or } \sqrt{2 \cdot 4} \\ \sqrt{12} \text{ or } \sqrt{3 \cdot 4} \\ \sqrt{18} \text{ or } \sqrt{2 \cdot 9} \\ \sqrt{24} \text{ or } \sqrt{6 \cdot 4} \\ \sqrt{32} \text{ or } \sqrt{2 \cdot 16} \\ \sqrt{75} \text{ or } \sqrt{3 \cdot 25} \end{array} \right\} \text{ is equivalent to } \left\{ \begin{array}{l} 2\sqrt{2} \\ 2\sqrt{3} \\ 3\sqrt{2} \\ 2\sqrt{6} \\ 4\sqrt{2} \\ 5\sqrt{3} \end{array} \right.$$

On the foregoing principles the operations of division are based, for  $\sqrt{a}$  divided by  $\sqrt{b}$  must be  $\frac{\sqrt{a}}{\sqrt{b}}$  or  $\sqrt{\frac{a}{b}}$ , and thus—

$$\left\{ \begin{array}{l} \frac{\sqrt{8}}{\sqrt{2}} \\ \frac{\sqrt{18}}{\sqrt{2}} \\ \frac{\sqrt{2}}{\sqrt{2}} \\ \frac{\sqrt{12}}{\sqrt{3}} \end{array} \right\} \text{ is equal to } \left\{ \begin{array}{l} \sqrt{\frac{8}{2}} \text{ or } \sqrt{4}, \text{ that is, } 2 \\ \sqrt{\frac{18}{2}} \text{ or } \sqrt{9}, \text{ that is, } 3 \\ 1 \\ \sqrt{\frac{12}{3}} \text{ or } \sqrt{4}, \text{ that is, } 2 \end{array} \right.$$

And again —

$$\left. \begin{array}{l} \sqrt[2]{2} \\ \sqrt[3]{3} \\ \sqrt[6]{6} \end{array} \right\} \text{ is equal to } \left\{ \begin{array}{l} \sqrt[4]{4} \text{ or } \sqrt[2]{2} \text{ or } \sqrt{2} \\ \sqrt[9]{9} \text{ or } \sqrt[3]{3} \text{ or } \sqrt[3]{9} \\ \sqrt[144]{144} \text{ or } \sqrt[6]{144} \text{ or } \sqrt[6]{24} \text{ or } \sqrt[6]{6 \times 4} \text{ or, lastly, } 2\sqrt[6]{6}. \end{array} \right.$$

591. It is unnecessary to follow this out in division and subtraction, because the numbers are merely connected by the signs + and -. For example,  $\sqrt{2}$  added to  $\sqrt{3}$  is expressed  $\sqrt{2} + \sqrt{3}$ ; and  $\sqrt{6}$  subtracted from  $\sqrt{10}$  is written  $\sqrt{10} - \sqrt{6}$ .

592. For the purpose of distinguishing these numbers from all others not similarly circumstanced, the latter, as well integral as fractional, are denominated *rational numbers*; and thence, when we speak of rational numbers, it is to be understood that we speak of integers or fractions.

#### IMPOSSIBLE OR IMAGINARY QUANTITIES.

593. The squares of numbers, whether negative or positive, as we have shown above, are always affected by the + or positive sign, for it has been seen that  $-a$  multiplied by  $-a$  produces  $+aa$ , in the same way as  $+a$  by  $+a$  produces the same result; and it was on this account that in the preceding section all the numbers whose roots were to be extracted were considered positive. If, however, the root of a negative number is to be extracted, a difficulty arises, because there is no assignable number whose square would be a negative quantity. If, for instance, we wanted the root of  $-4$ , we have to search for a number which, multiplied by itself, will produce  $-4$ . This number can be neither  $+2$  nor  $-2$ , because the squares of both will be  $+4$ , and not  $-4$ . Hence we must conclude that the square root of a negative number is neither positive nor negative, inasmuch as that the squares of negative numbers are affected by the sign +. The root must, therefore, belong to a species of numbers entirely distinct from all others, for it cannot be placed among either positive or negative numbers.

594. It has been observed that all positive numbers are greater than 0, and that all negative numbers are less than 0; hence whatever exceeds 0 is a positive number, and that which is less than 0 must be expressed by negative numbers. Thus the square roots of negative numbers are neither greater nor less than nothing. But they are not 0, because the product of 0 multiplied by 0 is 0, and does not, therefore, produce a negative number. But as all conceivable numbers are greater or less than 0, or are 0 itself, the square root of a negative number cannot be ranked among possible numbers; hence it is said to be an impossible quantity; and it is this which leads us to an idea of numbers which are naturally impossible. They are usually called *imaginary quantities*, from their existing only in imagination. Such expressions, therefore, as  $\sqrt{-1}$ ,  $\sqrt{-2}$ ,  $\sqrt{-3}$ ,  $\sqrt{-4}$ , &c. are impossible or imaginary numbers, because they represent roots of negative quantities; and of such numbers it may be said that they are neither nothing nor greater nor less than nothing; they are, therefore, imaginary or impossible. Though existing only in our imagination, we may form a sufficient idea of them, for we know that  $\sqrt{-4}$  expresses a number which, multiplied by itself, produces  $-4$ . For this reason there is nothing to prevent, in calculation, the use of these imaginary numbers.

595. The most obvious idea on the above matter is, that the square of  $\sqrt{-3}$ , for instance, or the product of  $\sqrt{-3}$  by  $\sqrt{-3}$  will be  $-3$ ; that the product of  $\sqrt{-1}$  by  $\sqrt{-1}$  is  $-1$ ; and, in general, that by multiplying  $\sqrt{-a}$  by  $\sqrt{-a}$  we obtain  $-a$ . Now  $-a$  is equal to  $+a$  multiplied by  $-1$ , and as the square root of a product is found by multiplying together the roots of its factors, it follows that the root of  $a$  multiplied by  $-1$  or  $\sqrt{-a}$  is equal to  $\sqrt{a}$  multiplied by  $\sqrt{-1}$ . But  $\sqrt{a}$  is a possible or real number, consequently the whole impossibility of an imaginary quantity may be always reduced to  $\sqrt{-1}$ . Thus  $\sqrt{-4}$  is equal to  $\sqrt{4}$  multiplied by  $\sqrt{-1}$ , and equal also to  $2\sqrt{-1}$ , for the  $\sqrt{4}$  is equal to 2; and so also  $\sqrt{-9}$  is reduced to  $\sqrt{9} \times \sqrt{-1}$  or  $3\sqrt{-1}$ , and similarly  $\sqrt{-16}$  is equal  $4\sqrt{-1}$ . Thus, also, as  $\sqrt{a}$  multiplied by  $\sqrt{b}$  produces  $\sqrt{ab}$ , we have  $\sqrt{b}$  for the value of  $\sqrt{-2}$  multiplied by  $\sqrt{-3}$ ; and  $\sqrt{4}$  or 2 for the value of the product of  $\sqrt{-1}$  by  $\sqrt{-4}$ . Hence we see how two imaginary numbers multiplied together produce one which is real or possible. But, on the other hand, a possible number multiplied by an impossible one always produces an imaginary product: thus,  $\sqrt{-3}$  by  $\sqrt{+5}$  gives  $\sqrt{-15}$ .

596. The same species of results prevail in division; for, as  $\sqrt{a}$  divided by  $\sqrt{b}$  makes  $\frac{\sqrt{a}}{\sqrt{b}}$ , it is clear that  $\sqrt{-4}$  divided by  $\sqrt{-1}$  will make  $\sqrt{+4}$  or 2, that  $\sqrt{+3}$  divided by  $\sqrt{-3}$  gives  $\sqrt{-1}$ ; and that 1 divided by  $\sqrt{-1}$  gives  $\sqrt[+1]{-1}$  or  $\sqrt{-1}$ , because 1 is equal to  $\sqrt{+1}$ . It has been already stated that the square root of a number has universally two values, one positive and the other negative; that  $\sqrt{4}$ , for example, is both  $+2$  and  $-2$ ; and that, generally,  $-\sqrt{a}$  as well as  $+\sqrt{a}$  exhibit equally the square root of  $a$ . It is

the same in the case of imaginary numbers, for the square root of  $-a$  is both  $+\sqrt{-a}$  and  $-\sqrt{-a}$ , but the signs  $+$  and  $-$  before the radical sign  $\sqrt{\phantom{x}}$  must not be confounded with the signs that come after it.

597. However, on first view, it may seem idle speculation thus to dwell on impossible numbers, the calculation of imaginary quantities is of the greatest importance, for questions constantly arise wherein it is impossible to say whether anything real or possible is or is not included, and when the solution of such a question leads to imaginary quantities, we are certain that what is required is impossible. Thus, suppose it were required to divide the number 12 into two such parts that the product of them may be 40. In resolving this question by the ordinary rules we find, for the parts sought,  $6+\sqrt{-4}$  and  $6-\sqrt{-4}$ , both imaginary numbers; hence we know that it is impossible to resolve the question. The difference is manifest in supposing the question had been to divide 12 into two parts whose product should produce 35, for it is evident that those parts must be 7 and 5.

598. A number twice multiplied by itself, or its square multiplied by the root, produces a cube or cubic number. Thus the cube of  $a$  is  $aaa$ , for it is the product of  $a$  multiplied by  $a$ , and that square  $aa$  again multiplied by  $a$ .

The cubes of the natural numbers are placed in the subjoined table:—

Numbers	1	2	3	4	5	6	7	8	9	10
Cubes	1	8	27	64	125	216	343	512	729	1000

Analysing the differences of these cubes, as we did those of the squares, by subtracting each cube from that following, the following series of numbers occur:—

7, 19, 37, 61, 91, 127, 169, 217, 271,

And in these there does not appear any regularity; but, taking the differences of these, we shall have the following series:—

12, 18, 24, 30, 36, 42, 48, 54, 60;

On the inspection of which it will be seen that the terms increase regularly by 6.

599. From the definition of a cube the cubes of fractional numbers are easily found: thus,  $\frac{1}{8}$  is the cube of  $\frac{1}{2}$ ,  $\frac{1}{27}$  is the cube of  $\frac{1}{3}$ , and  $\frac{8}{27}$  is the cube of  $\frac{2}{3}$ . Thus, also, we have only to take the cube of the numerator and that of the denominator separately, and for the cube of  $\frac{2}{3}$  we have  $\frac{8}{27}$ . To find the cube of a mixed number it must be reduced, first to a single fraction, and the process is then conducted in a similar manner. Thus, to find the cube of  $1\frac{1}{2}$  we must take the cube of  $\frac{3}{2}$ , which is  $\frac{27}{8}$  or  $3\frac{3}{8}$ , and the cube of  $1\frac{1}{2}$  is that of  $\frac{3}{2}$ , or  $\frac{27}{8}$ , or  $3\frac{3}{8}$ .

As  $aaa$  is the cube of  $a$ , that of  $ab$  will be  $aaabbb$ ; from which we learn, that if a number has two or more factors, its cube may be found by multiplying together the cubes of those factors. For instance, as 12 is equal to  $3 \times 4$ , the cube of 3, which is 27, if multiplied by the cube of 4, which is 64, gives us 1728, the cube of 12. Again, the cube of  $2a$  is  $8aaa$ , that is to say, 8 times greater than the cube of  $a$ ; so the cube of  $4a$  is  $64aaa$ , that is to say, 64 times greater than the cube of  $a$ .

600. The cube of a positive number will, of course, be positive: thus, that of  $+a$  will be  $+aaa$ ; but the cube of a negative will be negative, for  $-a$  by  $-a$  gives  $+aa$ , and that again multiplied by  $-a$  gives  $-aaa$ . So that it is not the same as with squares, for these are always positive.

#### CUBE ROOTS AND THE IRRATIONAL NUMBERS THAT RESULT FROM THEM.

601. As we can, by the mode above given, find the cube of any given number, so may we find one which, multiplied twice by itself, will produce that number. With relation to the cube this is called the *cube root*, or that whose cube is equal to the given number. When the number proposed is a real cube the solution is easy enough. For there is no difficulty in seeing that the cube of 1 is 1, that that of 2 is 8, that of 4 is 64, and so on: and equally that the cube root of  $-27$  is  $-3$ , and that of  $-216$  is  $-6$ . Similarly, if the proposed number be a fraction, as  $\frac{8}{125}$ , the cube root is  $\frac{2}{5}$ , and that of  $\frac{27}{343}$  is  $\frac{3}{7}$ . And last, in the case of a mixed number, as  $2\frac{10}{27}$ , the cube root will be  $\frac{2}{3}$  or  $1\frac{1}{3}$ , because  $2\frac{10}{27}$  is equal to  $\frac{54}{27}$ .

602. If, however, the proposed number be not a cube, its cube root cannot be expressed either in integers or fractional numbers. Thus, 43 is not a cube number; hence it is impossible to assign any number, integer or fractional, whose cube shall be exactly 43. We may, however, assert that the cube root of that number is greater than 3, for the cube of 3 is only 27, and less than 4, because the cube of 4 is 64. The cube root required lies, therefore, between 3 and 4. The cube root of 43 being greater than 3, by adding a fraction to 3 we may approach nearer to the value of the root, but we shall never be able to express the value exactly, because the cube of a mixed number can never be exactly equal to an integer, as 43 for instance. If we suppose  $3\frac{1}{2}$  or  $\frac{7}{2}$  to be the cube root required,

the error would be  $\frac{1}{8}$  for the cube of  $\frac{7}{8}$  is only  $\frac{343}{512}$  or  $42\frac{7}{8}$ . Thus we see that the cube root of 43 can be expressed neither by integers nor fractions. We obtain, however, a distinct notion of its magnitude, and, for the purpose of representing it, a sign  $\sqrt[3]{}$  is placed before the number which is read *cube root*, to distinguish it from the square root, which is frequently merely called the root. Thus  $\sqrt[3]{43}$  expresses the cube root of 43, that is, the number whose cube is 43.

603. It is evident that such expressions cannot belong to rational quantities, and that, indeed, they form a particular species of irrational quantities. Between them and square roots there is nothing in common, and it is impossible to express such a cube root by a square root, as, for example, by  $\sqrt{12}$ , for the square of  $\sqrt{12}$  being 12, its cube will be  $12\sqrt{12}$ , consequently irrational, and such cannot be equal to 43.

604. If the proposed number be a real cube the expressions become rational:  $\sqrt[3]{1}$  is equal to 1;  $\sqrt[3]{8}$  is equal to 2;  $\sqrt[3]{27}$  is equal to 3; and, generally,  $\sqrt[3]{aaa}$  is equal to  $a$ .

605. If it be proposed to multiply one cube root by another,  $\sqrt[3]{a}$ , for example, by  $\sqrt[3]{b}$ , the product must be  $\sqrt[3]{ab}$ ; for it has already been seen that the cube root of a product  $ab$  is found by multiplying together the cube root of its factors. Whence, also, if  $\sqrt[3]{a}$  be divided by  $\sqrt[3]{b}$ , the quotient will be  $\sqrt[3]{\frac{a}{b}}$ . And, further,  $2\sqrt[3]{a}$  is equal to  $\sqrt[3]{8a}$ , for 2 is the same as  $\sqrt[3]{8}$ ;  $3\sqrt[3]{a}$  is equal to  $\sqrt[3]{27a}$ , and  $b\sqrt[3]{a}$  is the same as  $\sqrt[3]{abbb}$ . So, reciprocally, when the number under the radical sign has a factor which is a cube, we may always get rid of it by placing its cube root before the sign. Thus, instead of  $\sqrt[3]{64a}$  we may write  $4\sqrt[3]{a}$ , and  $7\sqrt[3]{a}$  instead of  $\sqrt[3]{343a}$ . Hence  $\sqrt[3]{16}$  is equal to  $2\sqrt[3]{2}$ , because 16 is equal to  $8 \times 2$ . When a number proposed is negative, its cube root is not subject to the difficulties which we observed in speaking of square roots; for, as the cubes of negative numbers are negative, it follows that their cube roots are but negative. Thus  $\sqrt[3]{-8}$  is equal to  $-2$ , and  $\sqrt[3]{-27}$  to  $-3$ . So also  $\sqrt[3]{-12}$  is the same as  $-\sqrt[3]{12}$ , and  $\sqrt[3]{-a}$  may be expressed by  $-\sqrt[3]{a}$ . From which it may be deduced that the sign  $-$ , though found after the sign of the cube root, might have been as well placed before it. Hence we do not herein fall upon impossible or imaginary quantities, as we did in considering the square roots of negative numbers.

OF POWERS IN GENERAL.

606. A *power* is that number which is obtained by multiplying a number several times by itself. A square arises from the multiplication of a number by itself, a cube by multiplying it twice by itself, and these are powers of the number. In the former case we say the number is raised to the second degree or to the second power; and in the latter, the number is raised to the third degree or to the third power.

607. These powers are distinguished from one another by the number of times that the given number has been multiplied by itself. Thus the square is called the second power, because it has been removed to the second product by multiplication by itself; another multiplication by itself brings it to the third power or cube. When multiplied again by itself it becomes the fourth power, which is commonly called the *bi-quadrate*. From this will be readily comprehended what is meant by the fifth, sixth, seventh, &c. power of a number. After the fourth degree the names of the powers have only numeral distinctions. For the purpose of illustration, we may observe, that the powers of 1 must always be 1, because how often soever we multiply 1 into itself the product must be 1. The following table shows the powers of 2 and 3.

Powers.	Of the number 2.	Of the number 3.
I	2	3
II	4	9
III	8	27
IV	16	81
V	32	243
VI	64	729
VII	128	2187
VIII	256	6561
IX	512	19683
X	1024	59049
XI	2048	177147
XII	4096	531441
XIII	8192	1594323
XIV	16384	4782969
XV	32768	14348907
XVI	65536	43046721
XVII	131072	129140163
XVIII	262144	387420489

608. Of powers, those of the number 10 are the most remarkable, as being the foundation of our system of arithmetic. We will range in order a few of them, as under:—

I, II, III, IV, V, VI,  
10, 100, 1000, 10000, 100000, 1000000, &c.

To consider which more generally, we may take the powers of any number  $a$ , as placed in the following order:—

I, II, III, IV, V, VI,  
 $a$ ,  $aa$ ,  $aaa$ ,  $aaaa$ ,  $aaaaa$ ,  $aaaaaa$ , &c.

But in this mode of writing powers there is much inconvenience, because of the trouble of counting the figures and letters; for the purpose of ascertaining the powers intended to be represented, as, for example, the inconvenience of representing the hundredth power would be so great as to incumber almost to impossibility the expression of it. To avoid this inconvenience, an expedient has been devised which is sufficiently convenient, and which we have now to explain. To express, for example, the hundredth power of  $a$ , we write just above it to the right the power in question; thus,  $a^{100}$  means, conventionally,  $a$  raised to the hundredth power. The number thus written above that whose power or degree it represents is called an *exponent*, from its expounding the power or degree to which the number is to be raised, which, in the example we have adduced, is 100. Thus, then,  $a^2$  represents the square or second power of  $a$ , which, as we have seen, may be also represented by  $aa$ , either of these expressions being understood with equal facility. To express the cube or third power of  $a$  or  $aaa$ ,  $a^3$  is written, by which mode less room is occupied. So  $a^4$ ,  $a^5$ ,  $a^6$ , &c. respectively represent the fourth, fifth, and sixth powers of  $a$ . We may in this manner represent  $a$  by  $a^1$ , which, in fact, shows nothing more than that this letter is to be written only once. Such a series of powers as we here have noticed is called also a *geometrical progression*, because each term is once greater than the preceding.

609. As in this series of powers each term increases by multiplying the preceding term by  $a$ , thereby increasing the exponent by 1, so where any term is given the preceding one may be found if we divide by  $a$ , because it diminishes the exponent by 1: thus showing that the first term  $a^1$  must necessarily be  $\frac{a}{a}$  or 1; hence, if we proceed according to the exponents, we immediately perceive that the term which precedes the first must be  $a^0$ , from which follows this remarkable property, that  $a^0$  is always equal to 1, however great or small the value of the number  $a$  may be, even if  $a$  be nothing.

610. The series of powers may be continued in a retrograde order, and in two different ways: first, by dividing continually by  $a$ ; and, secondly, by diminishing the exponent by unity. In either mode the terms will be equal. The decreasing series, exhibited in both forms, is shown in the subjoined table, which is to be read from right to left.

	1	1	1	1	1	1	1	$a$
	$aaaaaa$	$aaaaa$	$aaaa$	$aaa$	$aa$	$a$		
First	$\frac{1}{a^6}$	$\frac{1}{a^5}$	$\frac{1}{a^4}$	$\frac{1}{a^3}$	$\frac{1}{a^2}$	$\frac{1}{a}$		
Second	$a^{-6}$	$a^{-5}$	$a^{-4}$	$a^{-3}$	$a^{-2}$	$a^{-1}$	$a^0$	$a^1$

Thus we come to the knowledge of powers whose exponents are negative, and are able to assign the precise value of those powers. And hence, from what has been said, it will be apparent that

$$\left. \begin{array}{l} a^0 \\ a^{-1} \\ a^{-2} \\ a^{-3} \\ a^{-4} \end{array} \right\} \text{ is equal to } \left\{ \begin{array}{l} 1 \\ \frac{1}{a} \\ \frac{1}{aa} \\ \frac{1}{a^3} \\ \frac{1}{a^4} \end{array} \right. \text{ or } \frac{1}{a^2} \text{ \&c.}$$

This gives us the facility of finding the powers of a product  $ab$ ; for they must be evidently  $ab$ , or  $a^1b^1$ ,  $a^2b^2$ ,  $a^3b^3$ ,  $a^4b^4$ ,  $a^5b^5$ , &c.; and the powers of fractions are found in the same manner; for example, those of  $\frac{a}{b}$  are

$$\frac{a^1}{b^1}, \frac{a^2}{b^2}, \frac{a^3}{b^3}, \frac{a^4}{b^4}, \frac{a^5}{b^5}, \frac{a^6}{b^6}, \text{ \&c.}$$

The only matter remaining, then, is the consideration of the powers of negative numbers. Take, for example, the powers of  $-a$ , and they will form the following series: —

$$-a, +aa, -a^3, +a^4, -a^5, +a^6, \&c.;$$

in which we immediately perceive that those powers are negative whose exponents are odd numbers, and that the powers with even numbers for exponents are positive. Thus the third, fifth, seventh, ninth, &c. powers have the sign  $-$ ; and the second, fourth, sixth, eighth, &c. powers are affected by the sign  $+$ .

#### CALCULATION OF POWERS.

611. The addition and subtraction of powers is effected by means of the signs  $+$  and  $-$  when the powers are different; for example,  $a^3 + a^2$  is the sum of the third and second powers of  $a$ ; and  $a^5 - a^4$  is the remainder when the fourth power of  $a$  is subtracted from the fifth; neither of which results can be abridged. If the powers are of the same kind or degree it is not necessary to connect them by signs, thus  $a^3 + a^3$  makes  $2a^3$ , &c.

612. But in the multiplication of powers, we must observe, first, that any power of  $a$  multiplied by  $a$ , gives the succeeding power, that is to say, the power whose exponent is one unit greater. Thus  $a^2$  multiplied by  $a$  produces  $a^3$ ; and  $a^3$  multiplied by  $a$  produces  $a^4$ . Similarly, if it be required to multiply by  $a$ , the powers of that number having negative exponents, 1 must be added to the exponent. Thus,  $a^{-1}$  multiplied by  $a$  produces  $a^0$  or 1; and this becomes most clearly seen by considering that  $a^{-1}$  is equal to  $\frac{1}{a}$  and that the product of  $\frac{1}{a}$  being  $\frac{a}{a}$ , it is consequently equal to 1. So  $a^{-2}$  multiplied by  $a$  produces  $a^{-1}$  or  $\frac{1}{a}$ ; and  $a^{-5}$  multiplied by  $a$  produces  $a^{-4}$ , and so on.

613. If it be required to multiply a power of  $a$  by  $aa$  or the second power, the exponent then becomes greater by 2. Thus the product of  $a^2$  by  $a^2$  is  $a^4$ ; that of  $a^2$  by  $a^3$  is  $a^5$ ; that of  $a^2$  by  $a^4$  is  $a^6$ ; and, generally,  $a^n$  multiplied by  $a^2$  makes  $a^{n+2}$ . In the case of negative exponents,  $a^{-1}$  or  $\frac{1}{a}$  is the product of  $a^{-1}$  by  $a^2$ . For  $a^{-1}$  being the same as  $\frac{1}{a}$ , it is just the same as if we had divided  $aa$  by  $a$ ; hence the product required is  $\frac{aa}{a}$  or  $a$ . In the same way,  $a^{-2}$  multiplied by  $a^2$  produces  $a^0$  or 1, and  $a^{-3}$  multiplied by  $a^2$  produces  $a^{-1}$ . It is equally clear that to multiply any power of  $a$  by  $a^3$ , its exponent must be increased by three units, consequently the product of  $a^n$  by  $a^3$  is  $a^{n+3}$ . And as often as it is required to multiply two powers of  $a$ , the product must be a power of  $a$  whose exponent is equal to the sum of those of the two given powers. For instance,  $a^4$  multiplied by  $a^5$  will make  $a^9$ , and  $a^{12}$  multiplied by  $a^7$  produces  $a^{19}$ , &c.

614. On the principles here exhibited, it is easy to determine the highest powers. Thus, to find the twenty-fourth power of 2, multiply the twelfth power by the twelfth power; because  $2^{24}$  is equal to  $2^{12} \times 2^{12}$ . But we have already seen that  $2^{12}$  is equal to 4096; hence the number 16777216, being the product of 4096 by 4096, is  $2^{24}$ , or the required power of 2.

615. In division we must observe that to divide a power of  $a$  by  $a$  the exponent must be diminished by unity. Thus  $a^3$  divided by  $a$  gives  $a^2$ ;  $a^0$  or 1 divided by  $a$  is equal to  $a^{-1}$  or  $\frac{1}{a}$ ;  $a^{-3}$  divided by  $a$  gives  $a^{-4}$ . So, if we have to divide a given power of  $a$  by  $a^2$ , the exponent must be diminished by 2, and if by  $a^3$ , three units must be subtracted from the exponent of the power proposed; and, generally, if it be required to divide any power of  $a$  by any other power of  $a$ , the rule is to subtract the exponent of the second from the exponent of the first of those powers. Thus  $a^{16}$  divided by  $a^9$  gives  $a^7$ ;  $a^5$  divided by  $a^6$  will give  $a^{-1}$ . So  $a^{-3}$  divided by  $a^4$  will give  $a^{-7}$ .

616. It is not difficult, then, from what has been said, to find the powers of powers, for it is effected by multiplication. Thus, if we have to seek the square or second power of  $a^3$ , we find  $a^6$ , and for the cube or third power of  $a^4$  we have  $a^{12}$ . To obtain the square of a power it is only necessary to double the exponent; for its cube, to triple the exponent, and so on. Thus  $a^{2n}$  is the square of  $a^n$ ,  $a^{3n}$  is the cube of  $a^n$ , and the seventh power of  $a^n$  is  $a^{7n}$ . The square of  $a^2$ , or square of the square of  $a$ , being  $a^4$ , is hence called *biquadrate*. The square of  $a^3$  is  $a^6$ ; hence the sixth power has received the name of the square-cube. To conclude, the cube of  $a^3$  being  $a^9$ , the ninth power has received the name of the *cubo-cube*.

#### ROOTS RELATIVELY TO POWERS IN GENERAL.

617. The square root of a given number is a number whose square is equal to that number; the cube root, that whose cube is equal to the given number: hence, whatever number be given, such roots of it will exist that their fourth, their fifth, or any other power, will be equal to the given number. For distinction sake, we shall call the square

root the *second root*, the cube root the *third root*, the bi-quadrato the *fourth root*, and so on. As the square or second root is marked by the sign  $\sqrt{\phantom{x}}$ , and the cubic or third root by the sign  $\sqrt[3]{\phantom{x}}$ ; so the fourth and fifth roots are respectively marked by the signs  $\sqrt[4]{\phantom{x}}$  and  $\sqrt[5]{\phantom{x}}$ , and so on. It is evident, according to this method of expression, the sign of the square root should be  $\sqrt[2]{\phantom{x}}$ ; but by common consent the figure is always left out; and we are to recollect that when a radical sign has no number prefixed to it, the square root is always meant. To give a still better explanation, we here subjoin some different roots of the number  $a$ , with their respective values:—

$$\left. \begin{array}{l} \sqrt{a} \\ \sqrt[3]{a} \\ \sqrt[4]{a} \\ \sqrt[5]{a} \\ \sqrt[6]{a} \end{array} \right\} \text{ is the } \left\{ \begin{array}{l} 2^{\text{d}} \\ 3^{\text{d}} \\ 4^{\text{th}} \\ 5^{\text{th}} \\ 6^{\text{th}} \end{array} \right\} \text{ root of } \left\{ \begin{array}{l} a \\ a \\ a \\ a \\ a \end{array} \right. \text{ and so on.}$$

And so, conversely,

$$\left. \begin{array}{l} \text{The } 2^{\text{d}} \\ \text{The } 3^{\text{d}} \\ \text{The } 4^{\text{th}} \\ \text{The } 5^{\text{th}} \\ \text{The } 6^{\text{th}} \end{array} \right\} \text{ power of } \left\{ \begin{array}{l} \sqrt{a} \\ \sqrt[3]{a} \\ \sqrt[4]{a} \\ \sqrt[5]{a} \\ \sqrt[6]{a} \end{array} \right\} \text{ is equal to } \left\{ \begin{array}{l} a \\ a \\ a \\ a \\ a \end{array} \right. \text{ and so on.}$$

618. Whether  $a$  be a small or a great number, we know what value to affix to all these roots of different degrees. If unity be substituted for  $a$  the roots remain constantly 1; for all powers of 1 have unity for their value. But if the number  $a$  be greater than 1, the roots will also all exceed unity; and further, if  $a$  represent a less number than 1, all the roots will be less than unity.

619. When the number  $a$  is positive, from what has been before said of square and cube roots, we know that all the other roots may be determined, and that they will be real and possible numbers. But if the number  $a$  is negative, its second, fourth, sixth, and all even roots become impossible, or imaginary numbers; because all the powers of an even order, whether of positive or of negative numbers, are affected by the sign +; whereas the third, fifth, seventh, and all odd roots become negative, but rational, because the odd powers of negative numbers are also negative. Hence an inexhaustible source of new kinds of surd or irrational quantities; for, whenever the number  $a$  is not a power represented by some one of the foregoing indices, it is impossible to express the root either in whole numbers or fractions, and it must therefore be ranked among the numbers called irrational.

#### THE REPRESENTATION OF POWERS BY FRACTIONAL EXPONENTS.

620. In the preceding subsections we have seen that the square of any power is found by doubling its exponent, and that in general the square or second power of  $a^n$  is  $a^{2n}$ . Hence the converse, that the square root of the power  $a^{2n}$  is found by dividing the exponent of that power by 2. Thus the square root of  $a^2$  is  $a^1$ ; that of  $a^6$  is  $a^3$ ; and as this is general, the square root of  $a^3$  is necessarily  $a^{\frac{3}{2}}$ , and that of  $a^7$  is  $a^{\frac{7}{2}}$ . Thus we have  $a^{\frac{1}{2}}$  for the square root of  $a^1$ , and hence  $a^{\frac{1}{2}}$  is equal to  $\sqrt{a}$ ; a new method of expressing the square root, which requires our particular attention.

621. To find the cube of a power, as  $a^n$ , we have already shown that its exponent must be multiplied by 3, hence its cube becomes  $a^{3n}$ ; and, conversely, to find the third or cube root of the power  $a^{3n}$ , we have only to divide the exponent by 3; hence the root is  $a^n$ . Thus, also,  $a^1$  or  $a$  is the cube root of  $a^3$ ,  $a^2$  that of  $a^6$ ,  $a^4$  that of  $a^{12}$ , and so on. The same reasoning is applicable to those cases in which the exponent is not divisible by 3; for it is evident that the cube root of  $a^2$  is  $a^{\frac{2}{3}}$ , as the cube root of  $a^4$  is  $a^{\frac{4}{3}}$  or  $a^{1\frac{1}{3}}$ . Hence the third or cube root of  $a$  or  $a^1$  will be  $a^{\frac{1}{3}}$ , which is the same as  $\sqrt[3]{a}$ .

622. The application is the same with roots of a higher degree: thus the fourth root of  $a$  will be  $a^{\frac{1}{4}}$ , which expression is of the same value as  $\sqrt[4]{a}$ . The fifth root of  $a$  will be  $a^{\frac{1}{5}}$ , which is equivalent to  $\sqrt[5]{a}$ , and so on in roots of higher degree. It would be possible, therefore, to dispense altogether with the radical signs, and to substitute fractional exponents for them; but as custom has sanctioned the signs, and as they are met with in all works on algebra, it would be wrong to banish them altogether from calculation. There is, however, sufficient reason to employ, as is frequently done, the other method of calculation; because it clearly corresponds with the nature of the thing. Thus, in fact, it is manifest that  $a^{\frac{1}{2}}$  is the square root of  $a$ , because we know that its square is equal to  $a^1$  or  $a$ .

623. What has been said will be sufficient to show how we are to understand fractional exponents; thus, if  $a^{\frac{1}{4}}$  should occur, it means that we are first to take the fourth power of  $a$  and then extract its cube or third root, and hence  $a^{\frac{1}{4}}$  is the same as  $\sqrt[3]{a^4}$ . Again, to find

the value of  $a^{\frac{3}{4}}$  the cube or third power of  $a$  or  $a^3$  must first be taken, and the fourth root of that power extracted, so that  $a^{\frac{3}{4}}$  is the same as  $\sqrt[4]{a^3}$ . So  $a^{\frac{4}{5}}$  is the same as  $\sqrt[5]{a^4}$ , &c. But when the fraction which represents the exponent is greater than unity, the value of the given quantity may be otherwise expressed. Let it, for instance, be  $a^{\frac{5}{2}}$ ; now this quantity is equivalent to  $a^{\frac{1}{2}}$  which is the product of  $a^2$  by  $a^{\frac{1}{2}}$ . Now  $a^{\frac{1}{2}}$  is equal to  $\sqrt{a}$ , wherefore  $a^{\frac{5}{2}}$  is equal to  $a^2 \sqrt{a}$ . So  $a^{\frac{10}{3}}$ , or  $a^{\frac{2}{3}}$ , is equal to  $a^3 \sqrt[3]{a}$ ; and  $a^{\frac{7}{3}}$ , that is,  $a^{\frac{1}{3}}$ , expresses  $a^3 \sqrt[3]{a^2}$ . From these examples the use of fractional exponents may be properly appreciated. This, however, extends also to fractional numbers, as follows.

624. Suppose  $\frac{1}{\sqrt{a}}$  is given, we know that it is equal to  $\frac{1}{a^{\frac{1}{2}}}$ ; now we have already seen that a fraction of the form  $\frac{1}{a^n}$  may be expressed by  $a^{-n}$ ; and instead of  $\frac{1}{\sqrt{a}}$ , we may use the expression  $a^{-\frac{1}{2}}$ . Also,  $\frac{1}{\sqrt[3]{a}}$  is equal to  $a^{-\frac{1}{3}}$ . So let the quantity  $\frac{a^2}{\sqrt[3]{a}}$  be proposed, it is transformable into  $\frac{a^2}{a^{\frac{1}{3}}}$ , which is the product of  $a^2$  by  $a^{-\frac{1}{3}}$ , and this is equivalent to  $a^{\frac{5}{3}}$ , or to  $a^{1\frac{2}{3}}$ , or, lastly, to  $\sqrt[3]{a^5}$ . These reductions will be facilitated by a little practice.

625. Each root may be variously represented, for  $\sqrt{a}$  is the same as  $a^{\frac{1}{2}}$ , and  $\frac{1}{2}$  being equivalent to the fractions  $\frac{2}{4}$ ,  $\frac{3}{6}$ ,  $\frac{4}{8}$ ,  $\frac{5}{10}$ ,  $\frac{6}{12}$ , &c., it is clear that  $\sqrt{a}$  is equal to  $\sqrt[4]{a^2}$ , to  $\sqrt[6]{a^3}$ , to  $\sqrt[8]{a^4}$ , and so on. Similarly,  $\sqrt[3]{a}$  is equal to  $a^{\frac{1}{3}}$ , and to  $\sqrt[6]{a^2}$ , to  $\sqrt[9]{a^3}$ , and to  $\sqrt[12]{a^4}$ . It is, moreover, manifest, that the number  $a$ , or  $a^1$  might be represented by the following radical expressions :

$$\sqrt[2]{a^2}, \sqrt[3]{a^3}, \sqrt[4]{a^4}, \sqrt[5]{a^5}, \&c.$$

a property of great use in multiplication and division; for, suppose we have to multiply  $\sqrt[3]{a}$  by  $\sqrt[4]{a}$ , we write  $\sqrt[12]{a^4}$  for  $\sqrt[3]{a}$ , and  $\sqrt[12]{a^3}$  instead of  $\sqrt[4]{a}$ , thus obtaining the same radical sign for both, and the multiplication being now performed, gives the product  $\sqrt[12]{a^7}$ . A similar result arises from  $a^{1\frac{1}{2}}$ , the product of  $a^{\frac{1}{2}}$  multiplied by  $a^1$ , for  $\frac{1}{2} + \frac{1}{2}$  is  $\frac{1}{1}$ , and, consequently, the product required is  $a^{\frac{3}{2}}$ , or  $\sqrt[2]{a^3}$ . If it were required to divide  $\sqrt{a}$  or  $a^{\frac{1}{2}}$  by  $\sqrt[3]{a}$  or  $a^{\frac{1}{3}}$ , we should have for the quotient  $a^{\frac{1}{2} - \frac{1}{3}}$ , or  $a^{\frac{1}{6}}$ , that is,  $a^{\frac{1}{6}}$ , or  $\sqrt[6]{a}$ .

#### METHODS OF CALCULATION AND THEIR MUTUAL CONNECTION.

626. In the foregoing passages have been explained the different methods of calculation in addition, subtraction, multiplication, and division, the involution of powers, and the extraction of roots. We here propose to review the origin of the different methods, and to explain the connection subsisting among them, in order that we may ascertain if it be possible or not for other operations of the same kind to exist; an inquiry which will illustrate the subjects that have been considered. We shall, for this purpose, here introduce a new sign =, which means that equality exists between the quantities it is used to join, and is read *equal to*. Thus, if I write  $a=b$ , it means that  $a$  is equal to  $b$ ; and so  $3 \times 8 = 24$ .

627. Addition, the process by which we add two numbers together and find their sum, is the first mode of calculation that presents itself to the mind. Thus if  $a$  and  $b$  be two given numbers whose sum is expressed by  $c$ , we shall have  $a+b=c$ . So that, knowing the two numbers  $a$  and  $b$ , we are taught by addition how to find the number  $c$ . Recollecting this comparison  $a+b=c$ , the question may be reversed by asking in what way  $b$  can be found when we know the numbers  $a$  and  $c$ . Let us, then, ascertain what number must be added to  $a$  that the sum may be  $c$ . Now, suppose, for instance,  $a=3$ , and  $c=8$ , it is evident we must have  $3+b=8$ , and  $b$  will be found by subtracting 3 from 8. So, generally, to find  $b$ , we must subtract  $a$  from  $c$ , whence arises  $b=c-a$ ; for, by adding  $a$  to both sides again, we have  $b+a=c-a+a$ , that is, as was supposed,  $=c$ . And this is the origin of subtraction, being, indeed, nothing more than an inversion of the question from which addition arises. Now it is possible that it may be required to subtract a greater from a lesser number; as, for example, 9 from 5. In this case we are furnished with the idea of a new kind of numbers, which are called negative numbers, because  $5-9=-4$ .

628. If several equal numbers are to be added together, their sum is found by multiplication, and is called a product. Thus  $ab$  expresses the product of the multiplication of  $a$  by  $b$ , or from  $a$  being added to itself  $b$  times. If this product be represented by  $c$ , we have  $ab=c$ , and we may, by the use of multiplication, determine the number  $c$  where the numbers  $a$  and  $b$  are known. Suppose, for example,  $a=3$ , and  $c=15$ , so that  $3b=15$ , we have to ascertain what number  $b$  represents, merely to find by what number  $b$  is to be multiplied, in order that the product may be 15, for to that is the question reduced: and this is division; for the number sought is found by dividing 15 by 3; hence, in general, the number  $b$  is found by dividing  $c$  by  $a$ , whence results the equation  $b=\frac{c}{a}$ .

But, frequently, the number  $c$  cannot be actually divided by the number  $a$ , the letter  $b$  having a determinate value; hence a new kind of numbers, called fractions, arises. For, suppose  $a=4$ ,  $c=3$ , so that  $4b=3$ , in this case  $b$  cannot be an integer, but must be a fraction, and we shall find that  $b$  can be no more than  $\frac{3}{4}$ . Multiplication, then, as we have seen, arises from the addition of equal quantities; so, from the multiplication of several equal quantities together, powers are derived, and they are represented in a general manner by the expression  $a^b$ , which signifies that the number  $a$  must be multiplied by itself as often as is pointed out by the number  $b$ , which is called the exponent, whilst  $a$  is called the root, and  $a^b$  the power. If this power be represented by the letter  $c$ , we have  $a^b=c$ , an equation in which are found the letters  $a$ ,  $b$ ,  $c$ . In treating of powers, it has been shown how to find the power itself, that is, the letter  $c$ , when the root  $a$  and its exponent  $b$  are given. Suppose, for instance,  $a=4$ , and  $b=3$ , we shall have  $c=4^3$ , or the third power of 4, which is 64, whence  $c=64$ . If we wish to reverse this question, we shall find that there are two modes of doing it. Let, for instance, two of the three numbers  $a$ ,  $b$ , and  $c$  be given. If it be required to find the third, it is clear that the question admits of three different suppositions, and hence, also, of three solutions. The case has been considered in which  $a$  and  $b$  were the numbers given; we may therefore suppose, further, that  $c$  and  $a$  or  $c$  and  $b$  are known, and that it is required to determine the third letter. Now, it must be observed, that between involution and the two operations which lead to it there is a great difference. For when, in addition, we reverse the question, there was only one way of doing it, and it was of no consequence whether we took  $c$  and  $a$  or  $c$  and  $b$  for the given numbers, for it is quite indifferent to the result whether we write  $a+b$  or  $b+a$ . And it is quite the same with multiplication; the letters  $a$  and  $b$  might be placed in each other's places at pleasure, the equation  $ab=c$  being exactly the same as  $ba=c$ . But in the calculation of powers, we cannot change the places of the letters; for instance, we could on no account write  $b^a$  for  $a^b$ . This we will illustrate by one example. Thus, let  $a=4$ , and  $b=3$ , we have  $a^b=4^3=64$ . But  $b^a=3^4=81$ , two very different results.

629. We may propose two more questions; one to find the root  $a$  by means of the given power  $c$ , and the exponent  $b$ ; the other to find the exponent  $b$ , the power  $c$  and the root  $a$  being known. The former of these questions has been answered in the subsection which treats of the extractions of roots: since, if  $b=2$ , and  $a^2=c$ , we know that  $a$  is a number whose square is equal to  $c$ , and consequently  $a=\sqrt{c}$ . So, if  $b=3$  and  $a^3=c$ , we know that the cube of  $a$  is equal to the given number  $c$ , and hence that  $a=\sqrt[3]{c}$ . We conclude, generally, from this, how the letter  $a$  may be determined by means of the letters  $c$  and  $b$ ; for  $a$  must necessarily be  $=\sqrt[b]{c}$ .

630. We have already seen that if the given number is not a real power (a contingency of frequent occurrence), the required root  $a$  can be expressed neither by integers nor fractions; nevertheless, as it must have a determinate value, the same consideration led us to the numbers called *surd* or *irrational numbers*, which, on account of the great variety of roots, are divisible into an infinite number of kinds. We were also, by the same enquiry, led to the knowledge of imaginary numbers.

631. Upon the second question, that of determining the exponent by means of the power  $c$  and the root  $a$ , is founded the very important theory of logarithms; an invention so important that without them scarcely any long calculation could be effected.

#### LOGARITHMS.

632. Resuming, then, the equation  $a^b=c$ , we in the doctrine of logarithms assume for the root a number taken at pleasure, but supposed to preserve its assumed value without variation. This being the case, the exponent  $b$  is taken, such that the power  $a^b$  becomes equal to a given number  $c$ , and this exponent  $b$  is said to be the *logarithm* of the number  $c$ . To express this, we shall use the letter  $L$  or the initial letters *log*. Thus, by  $b=L.c$  or  $b=\log.c$ , we mean that  $b$  is equal to the logarithm of the number  $c$ , or that the logarithm of  $c$  is  $b$ .

633. If the value of the root  $a$  is once established, the logarithm of any number  $c$  is but the exponent of that power of  $a$  which is equal to  $c$ . So that  $c$  being  $=a$ ,  $b$  is the logarithm of the power of  $a$ . If we suppose  $b=1$ , we have 1 for the logarithm of  $a^1$ ; hence  $L.a=1$ . Suppose  $b=2$ , we have 2 for the logarithm of  $a^2$ ; that is  $L.a^2=2$ . Similarly,  $L.a^3=3$ ,  $L.a^4=4$ ,  $L.a^5=5$ , and so on.

634. If  $b$  be made  $=0$ , 0 must be the logarithm of  $a^0$ ; but  $a^0=1$ ; consequently,  $L.1=0$ , whatever the value of the root  $a$ . If  $b=-1$ , then  $-1$  will be the logarithm of  $a^{-1}$ . Now  $a^{-1}=\frac{1}{a}$ ; therefore,  $L.\frac{1}{a}=-1$ . So, also,  $L.\frac{1}{a^2}=-2$ ;  $L.\frac{1}{a^3}=-3$ ;  $L.\frac{1}{a^4}=-4$ ; &c.

635. Thus, then, may be represented the logarithms of all the powers of  $a$ , and even those of fractions wherein unity is the numerator, and the denominator a power of  $a$ . We see, also, that, in all those cases, the logarithms are integers: but if  $b$  were a fraction it would be the logarithm of an irrational number. For suppose  $b=\frac{1}{2}$ , then  $\frac{1}{2}$  is the logarithm of  $a^{\frac{1}{2}}$ , or of  $\sqrt{a}$ ; consequently we have  $L.\sqrt{a}=\frac{1}{2}$ ; and in the same way,  $L.\sqrt[3]{a}=\frac{1}{3}$ ,  $L.\sqrt[4]{a}=\frac{1}{4}$ , &c.

636. If it be required to find the logarithm of another number  $c$ , it will be readily seen that it can neither be an integer nor a fraction. However, there must be such an exponent  $b$ , that the power  $a^b$  may become equal to the number proposed; we have, therefore,  $b = L.c$ , and, generally,  $a^{L.c} = c$ .

637. If we consider another number  $d$ , whose logarithm is represented in a similar manner by  $L.d$ ; then  $a^{L.d} = d$ ; and multiplying this expression by the preceding one  $a^{L.c} = c$ , we have  $a^{L.c + L.d} = cd$ . The exponent being always the logarithm of the power  $L.c + L.d = L.cd$ . If, instead of multiplying, we divide the former expression by the latter, we obtain  $a^{L.c - L.d} = \frac{c}{d}$ ; hence  $L.c - L.d = L.\frac{c}{d}$ .

638. From this we are led to the two principal properties of logarithms which are contained in the equations  $L.c + L.d = L.cd$ , and  $L.c - L.d = L.\frac{c}{d}$ : by the former whereof we learn that the logarithm of a product, as  $cd$ , is found by adding together the logarithms of the factors; by the last, that the logarithm of a fraction is determined by the subtraction of the logarithm of the denominator from that of the numerator. Whence it follows that to multiply or divide two numbers by one another, we have only to add or subtract their logarithms. This constitutes the immense advantage of logarithms in calculation; for when a question is incumbered with large quantities, it is, of course, much easier to add or subtract than to multiply and divide. In the involution of powers and the extraction of roots, logarithms are yet more useful. Thus, if  $d=c$ , we have by the first property  $L.c + L.c = L.cc$ ; consequently,  $L.cc = 2L.c$ . Similarly, we have  $L.c^3 = 3L.c$ ,  $L.c^4 = 4L.c$ , and, generally,  $L.c^n = nL.c$ .

Substituting fractional numbers for  $n$ , we shall have, for example,  $L.c^{\frac{1}{2}}$ , that is  $L.\sqrt{c} = \frac{1}{2}L.c$ . Lastly, if  $n$  represents negative numbers, we have  $L.c^{-1}$  or  $L.\frac{1}{c} = -L.c$ ;  $L.c^{-2}$  or  $L.\frac{1}{c^2} = 2L.c$ , and so on. For this not only follows from the equation  $L.c^n = nL.c$ , but also from  $L.1 = 0$ , as we have before shown.

In tables of logarithms which are calculated for all numbers, great assistance is rendered in performing the most prolix calculations. Suppose, for instance, the square root of the number  $c$  is sought, having found the logarithm of  $c$ , which is  $L.c$ , we have only to divide it by 2, that is, take the  $\frac{1}{2}$  of it, and we have the logarithm of the square root required; and the number in the table answering to that logarithm is the number required.

We have seen that the numbers 1, 2, 3, 4, 5, 6, &c., that is, all positive numbers, are logarithms of the root  $a$ , and of its positive powers, and consequently logarithms of numbers greater than unity; and, on the other hand, that negative numbers,  $-1, -2$ , &c., are logarithms of the fractions  $\frac{1}{a}, \frac{1}{aa}$ , &c., which are less than unity, but, nevertheless, greater than nothing; from whence it follows, that if the logarithm be positive, the number is always greater than unity, but, if negative, the number, though less than one, is yet greater than 0. Thus we cannot express the logarithms of negative numbers, and must conclude that they are impossible, and belong to the class of imaginary quantities. That this may be better understood, let us fix on a determinate number for the root  $a$ , such, for instance, as the number 10, on which the common logarithmic tables are formed, and which is, moreover, the basis of our arithmetic. Any other number, however, provided it be greater than unity, would answer the same purpose. The reason why the  $a=1$  would not suit is, that all the powers would be but equal to unity.

#### LOGARITHMIC TABLES NOW USED.

639. We set out with the supposition that the root  $a=10$ . Then the logarithm of any number  $c$  is the exponent to which the number 10 must be raised, so that the power resulting from it may be equal to the number  $c$ ; or if we denote the logarithm of  $c$  by  $L.c$ , we shall always have  $10^{L.c} = c$ .

The reader will recollect that the logarithm of 1 is always 0, and we have  $10^0 = 1$ . Hence—

$L.1 = 0$ ,  $L.10 = 1$ ,  $L.100 = 2$ ,  $L.1000 = 3$ ,  $L.10000 = 4$ ,  $L.100000 = 5$ ,  $L.1000000 = 6$ , &c.

Further, that

$L.\frac{1}{10} = -1$ ,  $L.\frac{1}{100} = -2$ ,  $L.\frac{1}{1000} = -3$ ,  $L.\frac{1}{10000} = -4$ ,  $L.\frac{1}{100000} = -5$ ,  $L.\frac{1}{1000000} = -6$ , &c.

The logarithms of the principal numbers are therefore readily determined; but those between them, as inserted in the tables, are not so easy to find. Our object here, however, is only a general view of the subject, with which we shall proceed. And, first, since  $L.1 = 0$  and  $L.10 = 1$ , it is manifest that the logarithms of all numbers between 1 and 10 lie between 0 and 1, that is greater than 0 and less than 1. Let us, then, consider the number 2, whose logarithm is certainly greater than 0, and yet less than unity. Now, if we represent this logarithm by the letter  $x$ , so that  $L.2 = x$ , the value of  $x$  must be such as

to give exactly  $10x=2$ . We immediately see that  $x$  must be considerably less than  $\frac{1}{2}$ , or, which is the same thing,  $10^{\frac{1}{2}}$  is greater than 2. For, squaring both sides, the square of  $10^{\frac{1}{2}}=10^1$ , and that of  $2=4$ , which latter is much less than the former. So  $\frac{1}{2}$  is still too great a value of  $x$ , that is to say,  $10^{\frac{1}{2}}$  is greater than 2; for the cube of  $10^{\frac{1}{2}}$  is 10, and that of 2 only 8. On the contrary, by making  $x=\frac{1}{3}$  we give it too small a value; for the fourth power of 10 being 10, and that of 2 being 16, it is evident that  $10^{\frac{1}{3}}$  is less than 2:  $x$  then, or  $L.2$ , is less than  $\frac{1}{3}$  and yet greater than  $\frac{1}{4}$ . In the same way we may determine, with respect to every fraction contained between  $\frac{1}{4}$  and  $\frac{1}{3}$ , whether it be too great or too small.

Trying, for example, with  $\frac{2}{7}$ , which is a trifle less than  $\frac{1}{3}$ , and greater than  $\frac{1}{4}$ ;  $10^{\frac{2}{7}}$  or  $10^{\frac{2}{7}}$  must = 2, or the seventh power of  $10^{\frac{2}{7}}$ , that is to say,  $10^2$  or 100 must be equal to the seventh power of 2; now the latter = 128, and is consequently greater than the former.

Hence we infer that  $10^{\frac{2}{7}}$  is also less than 2, and therefore that  $\frac{2}{7}$  is less than  $L.2$ , and that  $L.2$ , which was found less than  $\frac{1}{3}$ , is, however, greater than  $\frac{2}{7}$ . We might proceed in this investigation, but it is here unnecessary; because, from what has been shown, we prove that  $L.2$  has a determinate value; but continuing to represent it by  $x$ , so that  $L.2=x$ , we will show that when once known, the logarithms of an infinity of other numbers may be deduced. For this purpose we will use the equation already mentioned,  $L.cd=L.c+L.d$ , which comprehends the property, that the logarithm of a product is found by adding the logarithms of the factors.

640. First, as  $L.2=x$  and  $L.10=1$ , we have  $L.20=x+1$ ;  $L.200=x+2$ ,  $L.2000=x+3$ ;  $L.20000=x+4$  and  $L.200000=x+5$ , &c.

Further, as  $L.c^2=2L.c$ , and  $L.c^3=3L.c$ , and  $L.c^4=4L.c$ , &c., we have  $L.4=2x$ ;  $L.8=3x$ ;  $L.16=4x$ ;  $L.32=5x$ ;  $L.64=6x$ , &c.; and from this it follows, that  $L.40=2x+1$ ;  $L.400=2x+2$ ;  $L.4000=2x+3$ ;  $L.40000=2x+4$ , &c. Also,  $L.80=3x+1$ ,  $L.800=3x+2$ ,  $L.8000=3x+3$ ,  $L.80000=3x+4$ , &c. So  $L.160=4x+1$ ,  $L.1600=4x+2$ ,  $L.16000=4x+3$ , &c. Resuming the other fundamental equation  $L.\frac{c}{d}=L.c-L.d$ , let us suppose  $c=10$ , and  $d=2$ . Since  $L.10=1$ , and  $L.2=x$ , we shall have  $L.\frac{10}{2}$  or  $L.5=1-x$ , from which the following equations are deduced:—

$$L.50=2-x; L.500=3-x; L.5000=4-x, \&c.$$

$$L.25=2-2x; L.125=3-3x; L.625=4-4x, \&c.$$

$$L.250=3-2x; L.2500=4-2x; L.25000=5-2x, \&c.$$

$$L.1250=4-3x; L.12500=5-3x; L.125000=6-3x, \&c.$$

$$L.6250=5-4x; L.62500=6-4x; L.625000=7-4x, \&c.$$

and so on.

If we knew the logarithm of 3, we could determine another vast number of logarithms. For example: let the  $L.3$  be expressed by  $y$ . Then  $L.30=y+1$ ;  $L.300=y+2$ ;  $L.3000=y+3$ , &c.; and  $L.9=2y$ ;  $L.27=3y$ ;  $L.81=4y$ ;  $L.243=5y$ , &c.: as also  $L.6=x+y$ ;  $L.12=2x+y$ ;  $L.18=x+2y$ , and  $L.15=L.3+L.5=y+1-x$ .

From all this it is evident, that once knowing the logarithms of the prime numbers, the logarithms of all other numbers may be found by simple addition. Take, for example, the number 210, which is formed by the factors 2, 3, 5, 7, its logarithms will be  $L.2+L.3+L.5+L.7$ . In the same manner the number  $360=2 \times 2 \times 2 \times 3 \times 3 \times 5=2^3 \times 3^2 \times 5$ ; hence the  $L.360=3L.2+2L.3+L.5$ . It is therefore to the logarithms of the prime numbers that we must first apply ourselves, if we desire to construct tables of logarithms.

#### METHOD OF EXPRESSING LOGARITHMS.

641. It has been shown that the logarithm of 2 is greater than  $\frac{3}{10}$  and less than  $\frac{1}{2}$ , and that therefore the exponent of 10 lies between those two fractions, in order that the power may become = 2. But, although this is known to us, whatever fraction is assumed on this condition, the power resulting from it will always be an irrational number greater or less than 2; the logarithm, therefore, of 2 cannot be accurately expressed by such a fraction: hence we must be content with such an approximation to it as will render the error of no importance. For this purpose *decimal fractions* are used, which we shall now explain.

642. In the ordinary way of writing numbers by means of the ten figures or characters

0, 1, 2, 3, 4, 5, 6, 7, 8, 9,

the first figure on the right hand is the only one which has its natural signification; the figures in the second place have ten times the value they would have had in the first; those in the third place have a hundred times the value, and those in the fourth a thousand times, and so on; so that in proportion as they advance towards the left, they acquire a value ten times greater than they had in the preceding rank. Thus, in the number 1849, the figure 9 is in the first place on the right, and is just equal to 9. That in the second place is 4, but this figure, instead of 4, represents  $10 \times 4$  or 40. The figure 8 in the third

place is equal to  $100 \times 8$ , or 800. Lastly, the 1, which is the fourth to the left, is equal to 1000, hence the number is read as follows, —

*One thousand eight hundred and forty-nine.*

643. As the value of figures becomes in each rank always ten times greater as we go from the right towards the left, and as it continually becomes less as we proceed from the left to the right, we may by this law advance still further towards the right, and obtain figures whose value may continually decrease and become ten times less; but where this occurs, the place where the figures cease to have their natural value will continue to become ten times less. In this case, however, the place where the figures have their natural value is marked by a point placed after that rank. Thus, if, for instance, we meet with the number 54·76938, it must be thus understood: — the figure 4 in the first place has its natural value, and the second 5 means 50; but the figure 7 which comes after the point expresses only  $\frac{7}{10}$ ; the figure 6 is equal only to  $\frac{6}{100}$ ; the figure 9 is equal to  $\frac{9}{1000}$ ; the figure 3 to  $\frac{3}{10000}$ ; and the figure 8 to  $\frac{8}{100000}$ ; thus the more these figures advance towards the right, the more their values diminish, till at last those values become so small, that they may at last be considered as nothing. This species of numbers, then, are what are called *decimal fractions*, and in this way logarithms are represented in the tables. Thus the logarithm of 2 is expressed by 0·3010300, wherein we perceive, as the logarithm does not contain an integer, that its value is  $\frac{3}{10} + \frac{0}{100} + \frac{0}{1000} + \frac{0}{10000} + \frac{3}{100000} + \frac{0}{1000000} + \frac{0}{10000000}$ . The last two ciphers might have been omitted; they, however, serve to show that the logarithm quoted contains no parts which have 1000000 and 10000000 for the denominator. It is possible, however, that by continuing the series, smaller parts might have been found, which are neglected, except in extraordinary cases, on account of their extreme minuteness.

644. The logarithm of 3 is known by the tables to be 0·4771213, and, containing no integer, consists of the following fractions: —  $\frac{4}{10} + \frac{7}{100} + \frac{7}{1000} + \frac{1}{10000} + \frac{2}{100000} + \frac{1}{1000000} + \frac{3}{10000000}$ . This logarithm is, however, not expressed with the utmost exactness; we are only certain that the error is less than  $\frac{1}{10000000}$ , one so small, that there are few calculations in which it may not be neglected.

645. By this method of expressing logarithms, that of 1 will be represented by 0·0000000, since it is really = 0. The logarithm of 10 is 1·0000000, or exactly = 1. The logarithm of 100 is 2·0000000, or exactly = 2. Hence the logarithms of all numbers between 10 and 100, and, consequently consisting of only two figures, must be comprehended between 1 and 2, and are, therefore, expressed by 1 + a decimal fraction. Thus  $L.50 = 1·6989700$ ; its value, therefore, is unity added to  $\frac{6}{10} + \frac{9}{100} + \frac{8}{1000} + \frac{9}{10000} + \frac{7}{100000}$ . So it must be evident that between 100 and 1000 the logarithms of numbers are expressed by two integers with a decimal fraction; the logarithms of numbers between 10000 and 100000 by four integers joined to a decimal fraction, and so on. The *log.* 600, for example, is = 2·7781513; that of 2460 is 3·3909351, &c. But the logarithms of numbers less than 10, or those expressed by a single figure, do not contain an integer, and for this reason we find an 0 before the point. Hence there are two parts of a logarithm which require consideration: the former, that which precedes the point, and denoting the integers, if any; the other, the decimal fractions to be added to the integers. The first part, or integer, of a logarithm, usually called the *characteristic*, is easily determined from what has been already shown, — that is, it is 0 for all the numbers having but one figure; 1 for those which have two; 2 for those which have three, and generally less by one unit than the number of figures. Hence, if the logarithm of 5682 be required, we immediately perceive that the first part, or that of the integers, must be 3. So, reciprocally, when we see the integers of a logarithm, since the number it expresses is greater by one unit than the integer of the logarithm, we know, at once, the number answering to it. Thus, having 4·7771213 for the logarithm of an unknown quantity, it is evident that the number must have five figures, and exceed 10000. Now this number is 30000 for *log.* 30000 =  $L.3 + L.10000$ . Now the logarithm of 3 is known to be equal 0·4771213, and the logarithm of 10000 = 4, and the sum of those logarithms = 4·4771213.

646. From this it will be seen that the first object in considering a logarithm is the decimal fraction following the point, because, when that is known, it will serve for several numbers. For the proof whereof let us take the number 456. Its first part must be 2; and if we represent the decimal fraction which follows it by  $x$ , we have  $L.456 = 2 + x$ . If we continue to multiply by 10, we find  $L.4560 = 3 + x$ ;  $L.45600 = 4 + x$ ;  $L.456000 = 5 + x$ , and so on. But, if we divide instead of multiply by 10, we shall have  $45·6 = 1 + x$ ;  $L.45·6 = 0 + x$ ;  $L.0·456 = -1 + x$ ;  $L.0·0456 = -2 + x$ ;  $L.0·00456 = -3 + x$ , and so on.

647. Thus, all the numbers arising from the figures 456, whether preceded or followed by ciphers, have the same decimal fraction for the second part of the logarithm, and their differences lie in the integer before the point, which becomes negative when the number is less than 1. As ordinary calculators have difficulty in the use of negative numbers, it is customary to increase the integers of the logarithm by 10, or to write 10

instead of 0 before the point : by which process, instead of  $-1$  we have 9 ; instead of  $-2$  we have 8 ; instead of  $-3$  we have 7, &c. But, under these circumstances, it must be recollected that the characteristic has been made ten units too great ; nor must we assume that the number consists of ten, nine, or eight figures. We may easily see, in the case in question, that if the characteristic be less than 10, the figures of the number must be written after a point. If the characteristic be 9, we must begin at the first place after a point ; if it be 8, we must also place a cipher in the first row, and not begin to write the figures till the second. Thus 9·6589648 would be the logarithm of 0·456, and 8·6589648 the logarithm of 0·0456. This manner of using logarithms is, however, chiefly confined to the use of tables of sines.

648. Ordinary tables do not carry the decimals of logarithms further than seven places or figures, the last whereof must consequently represent the  $\frac{1}{10000000}$ th part, and we know that they do not err even by so small a part ; the error, therefore, is of no importance in ordinary cases. But there are cases, though of no importance in our application of their use, in which still greater exactness is required, and in such cases ordinary tables are not suited to the case.

649. From the circumstance of the characteristic being known at a glance, the tables never give it, but are restricted to the seven figures of the decimal fractions. There are tables wherein the logarithms of all numbers from 1 to 100000 and even those of greater numbers are given, by means of small additional tables, showing what is to be added in proportion to the figures which the proposed numbers have more than those in the tables. But from what has been said, we think the use of them will not be difficult ; and, supposing such tables before the reader, we propose the multiplication of the numbers 2401 and 343. The addition of the logarithms of these numbers will, from what has been shown, give the product, as follows :—

$$\begin{array}{r} \text{L. } 343 = 2.5352941 \\ \text{L. } 2401 = 3.3803922 \end{array} \left. \vphantom{\begin{array}{r} \text{L. } 343 \\ \text{L. } 2401 \end{array}} \right\} \text{added,}$$

$$\begin{array}{r} 5.9156863 \\ \underline{6847} \end{array} \left. \vphantom{\begin{array}{r} 5.9156863 \\ 6847 \end{array}} \right\} \text{subtracted,}$$

$$\underline{\hspace{1.5cm}} 16$$

Hence the number sought is 823543. For the sum is the logarithm of the product required, and its characteristic 5 exhibits a product composed of 6 figures, and they are found, by the decimal product and the fraction, to be 823543.

650. But it is in the extraction of roots that logarithms are most serviceable ; for example, if we have to extract the square root of 10, we have only to divide the logarithm of 10, which is 1·0000000, by 2, the quotient 0·5000000 is the logarithm of the root required, which, in the tables, answers so nearly to 3·16228, whose square answers to 10 so nearly, that it is only one hundred thousandth part too great.

651. The operation, in addition, of expressions consisting of several terms is frequently represented merely by signs, each expression being placed between two parentheses and connected with the rest by means of the sign +. Thus, to add the expressions  $a + b + c$  and  $d + e + f$  the sum is thus represented :—

$$(a + b + c) + (d + e + f).$$

This, however, is rather representing than performing addition ; but, if the parentheses are left out it is then actually performed ; for, as the number  $d + e + f$  is to be added to the other, it is to be done by joining to it +  $d$ , then +  $e$ , and then +  $f$ . If any term is affected by the sign  $-$ , it must be joined in the proper way with that sign. To illustrate this, let us consider an example in pure numbers ; for example,  $16 - 9$  to  $13 - 5$ . If we begin by adding 16, we shall have  $13 - 5 + 16$ . But this was adding too much, since what was to be added was  $16 - 9$ , and it is therefore clear that we have added too much by 9 ; we must, therefore, take away the 9 by writing it with the negative sign, and thus we shall have the true sum—

$$13 - 5 + 16 - 9,$$

which shows that the sums result from writing all the terms each with its proper sign.

652. If, therefore, it were required to add the expression  $d - e - f$  to  $a - b + c$ , the sum must be expressed as under :—

$$a - b + c + d - e - f ;$$

wherein it is of no importance in what order we write the terms, if their proper signs be preserved ; the sum, for example, might be written

$$c - e + a - f + d - b.$$

Hence it will be seen that addition is attended with no difficulty, be the forms of the terms to be added together what they may. Thus, suppose we wished to add the expressions  $2a^3 + 6\sqrt{b} - 4L.c$ , and  $5\sqrt{a} - 7c$ , they would be written

$$2a^3 + 6\sqrt{b} - 41c + 5\sqrt{a} - 7c,$$

or in any other order, provided the proper signs are retained.

653. But it is often possible to abridge the representation of these, as when two or more terms destroy each other; thus, if in the same sum are found the terms  $+a-a$ , or  $3a-4a+a$ , or when two or more terms may be reduced to one: thus,—

$$3a+2a=5a; \quad 7b-3b=+4b;$$

$$-6c+10c=+4c;$$

$$5a-8a=-3a; \quad -7+b=-6b;$$

$$-3c-4c=-7c;$$

$$2a-5a+a=-2a; \quad -3b-5b+2b=-6b.$$

If, therefore, two or more terms are the same with regard to letters, their sum may be abridged; but such cases must not be confounded with such as  $2aa+3a$  or  $2b^3-b^4$ , which cannot be abridged.

654. By considering some more examples of reduction, we shall be led to the discovery of an important point,—namely, that if we add together the sum of two numbers  $a+b$  and their difference  $a-b$ , we obtain twice the greater of those two numbers. For, in adding  $a+b$  and  $a-b$ , our rule gives  $a+b+a-b$ . Now  $a+a=2a$  and  $b-b=0$ ; the sum, therefore, is  $2a$ . We here subjoin two examples:—

$$\begin{array}{r} 3a-2b-c \\ 5b-6c+a \\ \hline \text{Sum} \dots 4a+3b-7c \end{array}$$

$$\begin{array}{r} a^3-2aab+2abb \\ -aab+2abb+b^3 \\ \hline \text{Sum} \dots a^3-3aab+4abb+b^3 \end{array}$$

#### THE SUBTRACTION OF COMPOUND QUANTITIES.

655. To represent subtraction each expression is inclosed within two parentheses joining, by the sign  $-$ , the expression to be subtracted to that from which it is to be subtracted. Thus, if  $d-e+f$  is to be subtracted from  $a-b+c$ , the remainder is written thus:—

$$(a-b+c)-(d-e+f);$$

and this method sufficiently shows which of the two expressions is to be subtracted from the other.

656. But if actual subtraction is to be performed, we must observe, first, that when we subtract a positive quantity  $+b$  from another quantity  $+a$ , we obtain  $a-b$ ; and, secondly, when we subtract a negative quantity  $-b$  from  $a$ , we obtain  $a+b$ ; for, to discharge the debt of a person is the same as to give him something. Suppose the expression  $b-d$  is to be subtracted from the expression  $a-c$ , we must first take away  $b$ , which gives  $a-c-b$ . We have, however, taken away too much by the quantity  $d$ . Since we had to subtract only  $b-d$ , restoring, then, the value of  $d$ , we shall have

$$a-c-b+d;$$

from which it is evident that the terms of the expression to be subtracted must change their signs, and with such contrary signs be joined to the terms of the other expressions.

657. It is therefore, by means of this rule, easy to perform subtraction; for it is only necessary to write the expression from which we are to subtract, and join the other to it, without any change but that of the signs. Thus, in the first example, where it was required to subtract the expression  $d-e+f$  from  $a-b+c$ , we obtain  $a-b+c-d+e-f$ . This will be rendered quite clear by an example in numbers. If, for example, we subtract  $5-3+6$  from  $7-2+3$ , we obtain

$$7-2+3-5+3-6;$$

for  $7-2+3=8$ , also  $5-3+6=8$ , now  $8-8=0$ .

658. Subtraction being then thus easily performed, we have only to observe that if, in the remainder, two or more terms are found entirely similar with regard to the letters, the remainder may be reduced to an abridged form by the rules for a similar purpose given in addition. Suppose we have to subtract from  $a+b$  or the sum of two quantities their difference, or  $a-b$ , we shall have  $a+b-a+b$ : now  $a-a=0$  and  $b+b=2b$ ; the remainder is therefore  $2b$ , that is to say, double the least of the quantities. The following examples will further illustrate what we have said:—

$$\begin{array}{r} aa+ab+bb \\ bb+a-b-aa \\ \hline +2aa \end{array} \quad \begin{array}{r} 3a-4b+5c \\ 2b+4c-6a \\ \hline 9a-6b+c \end{array} \quad \begin{array}{r} a^3+3aab+3abb+b^3 \\ a^3-3aab+3abb-b^3 \\ \hline 6aab+2b^3 \end{array} \quad \begin{array}{r} \sqrt{a}+2\sqrt{b} \\ \sqrt{a}-3\sqrt{b} \\ \hline +5\sqrt{b} \end{array}$$

#### THE MULTIPLICATION OF COMPOUND QUANTITIES.

659. Merely to represent compound quantities, each of the expressions to be multiplied together is placed within parentheses, and they are then to be joined together either with

or without the sign  $\times$  between them. Thus, to represent the product of the two expressions  $a-b+c$  and  $d-e+f$  when multiplied together, we write

$$(a-b+c) \times (d-e+f);$$

and this mode of expressing products is much used, because it shows the factors whereof they are composed. To show, however, how any multiplication is to be actually conducted, let us take for example such a quantity as  $a-b+c$  to be multiplied by 2; here each term is separately multiplied by that number, so that for the product we have

$$2a-2b+2c;$$

and the same takes place with all other numbers. Suppose, for example,  $d$  had been the number by which we had been required to multiply,

$$ad-bd+cd$$

would have been the product obtained.

660. We have here supposed that  $d$  was a positive number, but had the factor been negative, as  $-e$ , the rule formerly given must have been applied, namely, that unlike signs multiplied together produce  $-$ , and like signs produce  $+$ . We should therefore have had

$$-ae+be-ce.$$

661. To show the mode of multiplying a quantity  $A$  by a compound quantity  $d-e$ , it will be convenient to take for example one in common numbers: let  $A$ , for instance, be multiplied by  $7-3$ . Here it is manifest we have to take  $4A$ ; for if we first take  $A$  seven times, it will be necessary to subtract  $3A$  from that product. In general, therefore, if we have to multiply by  $d-e$ ,  $A$  must be first multiplied by  $d$  and then by  $e$ , and the last product must be subtracted from the first, whence we shall have  $dA-eA$ . Suppose  $A=a-b$ , and that this quantity is to be multiplied by  $d-e$ , we shall have

$$\begin{array}{l} dA=ad-bd \\ eA=ae-be \end{array}$$

$$\text{The product required} = ad-bd-ae+be.$$

Since, then, we know without doubt the product  $(a-b) \times (d-e)$ , we may now give the same example of multiplication under a different form; thus

$$\begin{array}{r} a-b \\ d-e \\ \hline ad-bd-ae+be; \end{array}$$

from which we learn that each term of the upper expression must be multiplied by each term of the lower; and that, with regard to the signs, the rule often before given must be strictly observed. From what has been said, we presume no difficulty will arise in calculating the following example, namely, to multiply  $a+b$  by  $a-b$ .

$$\begin{array}{r} a+b \\ a-b \\ \hline aa+ab \\ -ab-bb \end{array}$$

$$\text{Product} = aa-bb$$

For  $a$  and  $b$  any determinate numbers may be substituted, so that out of the above examples arises the following theorem; viz. the product of the sum of two numbers multiplied by their difference is equal to the difference of the squares of those numbers; which may be thus expressed—

$$(a+b) \times (a-b)=aa-bb$$

From this last follows another theorem; namely, the difference of two square numbers is always a product, and divisible both by the sum and the difference of the roots of those two squares, consequently the difference of two squares can never be a prime number. We will now present to the reader some other examples:—

$$\begin{array}{r} \text{(I.) } 2a-3 \\ a+2 \\ \hline 2aa-3a \\ +4a-6 \\ \hline 2aa+a-6 \end{array}$$

$$\begin{array}{r} \text{(II.) } 4aa-6a+9 \\ 2a+3 \\ \hline 8a^3-12aa+18a \\ -12aa-18a+27 \\ \hline 8a^3+27 \end{array}$$

$$\begin{array}{r} \text{(III.) } 3aa-2ab-bb \\ 2a-4b \\ \hline 6a^3-4aab-2abb \\ -12aab+8abb+4b^3 \\ \hline 6a^3-16aab+6abb+4b^3 \end{array}$$

$$(IV.) \begin{array}{r} aa + 2ab + 2bb \\ aa - 2ab + 2bb \\ \hline a^4 + 2a^3b + 2aabb \\ - 2a^3b - 4aabb - 4ab^3 \\ + 2aabb + 4ab^3 + 4b^4 \\ \hline a^4 + 4b^4 \end{array}$$

$$(V.) \begin{array}{r} 2aa - 3ab - 4bb \\ 3aa - 2ab + bb \\ \hline 6a^4 - 9a^3b - 12aabb \\ - 4a^3b + 6aabb + 8ab^3 \\ + 2aabb - 3ab^3 - 4b^4 \\ \hline 6a^4 - 13a^3b - 4aabb + 5ab^3 - 4b^4 \end{array}$$

$$(VI.) \begin{array}{r} aa + bb + cc - ab - ac - bc \\ a + b + c \\ \hline a^3 + abb + acc - aab - aac - abc \\ + aab + b^3 + bcc - abb - abc - bbc \\ + aac + bcc + c^3 - abc - acc - bcc \\ \hline a^3 - 3abc + b^3 + c^3 \end{array}$$

When more than two quantities are to be multiplied together, it will be obvious that, having multiplied two of them together, their product must be multiplied by one of the remaining ones, and so on. The order in which they are multiplied is a matter of no importance. Thus, suppose in common numbers the four following factors:—

$$\begin{array}{cccc} (I.) & (II.) & (III.) & (IV.) \\ (1+2) & (1+2+4) & (2-1) & (2+1+4) \end{array}$$

Multiplying the factors I. and II., we have  $3 \times 7 = 21$ . From factors III. and IV. we have  $1 \times 7 = 7$ . Now, multiplying the product of I. and II. by the second product of III. and IV., we have  $21 \times 7 = 147$ . Let us now change the order by multiplying first I. and III. together, and then II. and IV. The first product will be that of  $3 \times 1 = 3$ , the second that of  $7 \times 7 = 49$ . Then  $3 \times 49 = 147$ , as in the first operation: and the same result will be produced in whatever order they are multiplied.

#### THE DIVISION OF COMPOUND QUANTITIES.

662. To represent division, we either use the ordinary mark of fractions, which is to separate by a line the dividend or numerator from the divisor or denominator: thus, to divide  $a+b$  by  $c+d$ , the quotient is thus represented  $\frac{a+b}{c+d}$ ; or, the two quantities being enclosed within parentheses, we place two points between the divisor and the dividend: thus,  $(a+b) : (c+d)$ . Each of these expressions is read  $a+b$  divided by  $c+d$ .

663. If it be required to divide a compound quantity by a simple one, each term must be divided separately. Thus,  $10a - 6b + 8c$  divided by 2 gives  $5a - 3b + 4c$ ; and  $(aa - 4ab) : (a)$  gives  $a - 4b$ . So, also,  $(a^3 - 2aab + 3abb) : (a) = aa - 2ab + 3bb$ ;  $(4aab - 6aac + 8abc) : (2a) = 2ab - 3ac + 4bc$ ;  $(9abc - 12abbc + 15abcc) : (3abc) = 3a - 4b + 5c$ , &c.

664. If a term in the dividend is not divisible by the divisor, the quotient is represented by a fraction, as in the division of  $a+b$  by  $a$  the quotient is  $1 + \frac{b}{a}$ ; so also,

$$(aa - ab + bb) : (aa) = 1 - \frac{b}{a} + \frac{bb}{aa}.$$

Likewise, if we divide  $2a+b$  by 2, we obtain the quotient of  $a + \frac{b}{2}$ ; and here we must observe, that, instead of  $\frac{b}{2}$  we may write  $\frac{1}{2}b$ , because  $\frac{1}{2}$  times  $b$  is equal to  $\frac{b}{2}$ . And, similarly,  $\frac{b}{3}$  is the same as  $\frac{1}{3}b$ , and  $\frac{2b}{3}$  the same as  $\frac{2}{3}b$ , &c.

665. When the divisor is a compound quantity, division is not so easily performed; and when it cannot be so performed, we can do no more than represent the quotient by a fraction in the manner already described. We will, however, begin with some examples in which actual division will succeed. Suppose we have to divide  $ac - bc$  by  $a - b$ : the quotient must, of course, be such that, when multiplied by the divisor  $a - b$ , it will produce the dividend  $ac - bc$ . Now, this quotient must contain  $c$ , for, without it, we could not obtain  $ac$ . In order, then, to try whether  $c$  is the whole quotient, we have only to multiply it by the divisor. Now, in the present case, if we multiply  $a - b$  by  $c$ , we have  $ac - bc$ , which is the exact dividend, so that  $c$  is the whole quotient. It is equally clear that  $(aa + ab) : (a + b) = a$ ;  $(3aa - 2ab) : (3a - 2b) = a$ ;  $(6aa - 9ab) : (2a - 3b) = 3a$ , &c. Thus, then, we cannot fail to find a part of the quotient; and if what we have found when multiplied by the divisor does not exhaust the dividend, we have only to divide the remainder by the divisor, to obtain a second part of the quotient; and so proceed till we have found the whole of it.

666. Let us, as an example, divide  $aa + 3ab + 2bb$  by  $a + b$ . In the first place, it is clear that the quotient will contain  $a$ , for without that term we could not obtain  $aa$ . Multiply-

ing, then, the divisor  $a + b$  by  $a$ , we have  $aa + ab$ , which quantity subtracted from the dividend leaves the remainder  $2ab + 2bb$ . Dividing this by  $a + b$ , it is evident the quotient must contain the term  $2b$ . Now,  $2b$  multiplied by  $a + b$  produces exactly  $2ab + 2bb$ , and therefore  $a + 2b$  is the quotient required, which, multiplied by the divisor  $a + b$ , ought to produce the dividend  $aa + 3ab + 2bb$ . Below, the operation will be seen more strikingly.

$$\begin{array}{r}
 (a+b)aa+3ab+2bb(a+2b \\
 aa+ab \\
 \hline
 2ab+2bb \\
 2ab+2bb \\
 \hline
 0
 \end{array}$$

The operation is facilitated by choosing one of the terms of the divisor to be written first, and then, in arranging the terms of the dividend, begin with the highest powers of the first term of the divisor. This term was  $a$  in the preceding example; and in the following examples it will be seen that the system is followed.

$$(I.) \quad (a-b)a^3 - 3aab + 3abb - b^3 (aa - 2ab + bb)$$

$$\begin{array}{r}
 a^3 - aab \\
 \hline
 -2aab + 3abb \\
 -2aab + 2abb \\
 \hline
 abb - b^3 \\
 abb - b^3 \\
 \hline
 0
 \end{array}$$

$$(II.) \quad (a+b)aa - bb(a-b)$$

$$\begin{array}{r}
 aa + ab \\
 \hline
 -ab - bb \\
 -ab - bb \\
 \hline
 0
 \end{array}$$

$$(III.) \quad 3a - 2b) 18aa - 8bb (6a + 4b)$$

$$\begin{array}{r}
 18aa - 12ab \\
 \hline
 12ab - 8bb \\
 12ab - 8bb \\
 \hline
 0
 \end{array}$$

$$(IV.) \quad (a+b)a^3 + b^3 (aa - ab + bb)$$

$$\begin{array}{r}
 a^3 + aab \\
 \hline
 -aab + b^3 \\
 -aab - abb \\
 \hline
 +abb + b^3 \\
 +abb + b^3 \\
 \hline
 0
 \end{array}$$

$$(V.) \quad 2a - b) 8a^3 - b^3 (4aa + 2ab + bb)$$

$$\begin{array}{r}
 8a^3 - 4aab \\
 \hline
 4aab - b^3 \\
 4aab - 2abb \\
 \hline
 2abb - b^3 \\
 2abb - b^3 \\
 \hline
 0
 \end{array}$$

$$(VI.) \quad aa - 2ab + bb) a^4 - 4a^3b + 6aabb - 4ab^3 + b^4 (aa - 2ab + bb)$$

$$\begin{array}{r}
 a^4 - 2a^3b + aabb \\
 \hline
 -2a^3b + 5aabb - 4ab^3 \\
 -2a^3b + 4aabb - 2ab^3 \\
 \hline
 aabb - 2ab^3 + b^4 \\
 aabb - 2ab^3 + b^4 \\
 \hline
 0
 \end{array}$$

$$(VII.) \quad aa - 2ab + 4bb) a^4 + 4aabb + 16b^4 (aa + 2ab + 4bb)$$

$$\begin{array}{r}

 \underline{3xx - 6x^3 + 3x^4} \\
 -x^3 + 2x^4 - x^5 \\
 \underline{-x^3 + 2x^4 - x^5} \\
 0
 \end{array}$$

## THE RESOLUTION OF FRACTIONS INTO INFINITE SERIES.

667. We have already said that when the dividend is not divisible by the divisor, the quotient is expressed by a fraction. Thus, if we have to divide 1 by  $1-a$ , we obtain the fraction  $1 - \frac{1}{a}$ . We may, however, attempt the division and continue it at pleasure according to the rules given, and, though under other forms, the true quotient will be found. Thus —

$$\begin{array}{rcl}
 \text{(I.) } 1-a) 1 & (1 + \frac{a}{1-a} & \text{(II.) or } 1-a) 1 \quad (1 + a + \frac{aa}{1-a} \\
 \underline{1-a} & & \underline{1-a} \\
 \text{remainder } a & & a \\
 & & \underline{a - aa} \\
 & & \text{remainder } aa
 \end{array}$$

To find a greater number of forms we need only continue dividing  $aa$  by  $1-a$ .

$$\begin{array}{rcl}
 \text{(III.) } 1-a) aa & (aa + \frac{a^3}{1-a} & \text{(IV.) then } 1-a) a^3 \quad (a^3 + \frac{a^4}{1-a} \\
 \underline{aa - a^3} & & \underline{a^3 + a^4} \\
 a^3 & & a^4 \\
 \text{(V.) and, again, } 1-a) a^4 & (a^4 + \frac{a^5}{1-a} & \\
 \underline{a^4 - a^5} & & \\
 a^5 & & 
 \end{array}$$

All which shows that the fraction is equally represented under the following forms:

(I.)  $1 + \frac{1}{1-a}$ ; (II.)  $1 + a + \frac{aa}{1-a}$ ; (III.)  $1 + a + aa + \frac{a^3}{1-a}$ ; (IV.)  $1 + a + aa + a^3 + \frac{a^4}{1-a}$ , (V.)  $1 + a + aa + a^3 + a^4 + \frac{a^5}{1-a}$ , &c. Now, considering the first of these expressions, which is  $1 + \frac{a}{1-a}$ , and remembering that 1 is the same as  $\frac{1-a}{1-a}$  we have

$$1 + \frac{a}{1-a} = \frac{1-a}{1-a} + \frac{a}{1-a} = \frac{1-a+a}{1-a} = \frac{1}{1-a};$$

and following the same process with respect to the second expression,  $1 + a + \frac{aa}{1-a}$ , that is, if we reduce the integer part  $1 + a$  to the same denominator  $1-a$ , we have  $\frac{1-aa}{1-a}$ , to which if  $+\frac{aa}{1-a}$  be added, we shall have  $\frac{1-aa+aa}{1-a}$ , that is  $\frac{1}{1-a}$ .

668. In the third expression,  $1 + a + aa + \frac{a^3}{1-a}$  the integer reduced to the denominator  $1-a$  make  $\frac{1-a^3}{1-a}$ , and if to that be added the fraction  $\frac{a^3}{1-a}$  we have  $\frac{1}{1-a}$ ; whence all these expressions are equal in value to  $\frac{1}{1-a}$ , the proposed fraction. Hence, without the trouble of further division, we may continue the series to any extent, for we shall have  $\frac{1}{1-a} = 1 + a + aa + a^3 + a^4 + a^5 + a^6 + a^7 + \frac{a^8}{1-a}$ ; it may, indeed, be continued without end. On

this account it may be said that the proposed fraction has been resolved into an infinite series; and we arrive at the same time at the conclusion, that the value of this infinite series is the same as that of the fraction  $\frac{1}{1-a}$ . However astonishing this may seem, upon the consideration of some particular cases, it will be easily understood. Let us suppose that  $a=1$ . The series will then become  $1+1+1+1+1+1+1$ , &c., and the fraction  $\frac{1}{1-1}$ , to which it must be equal, become  $\frac{1}{0}$ , which, we have before seen, is a number infinitely great, and herein it is satisfactorily confirmed. If  $a$  be equal to 2, the series becomes  $=1+2+4+8+16+32+64$ , &c. to infinity, and its value must be  $\frac{1}{1-2}$ , that is to say  $\frac{1}{-1}=-1$ , which will perhaps appear absurd, until it is recollected that if we want to stop at any term of the series we must join the fraction which remains. Thus, if we stop at 64, after having written  $1+2+4+8+16+32+64$ , we must join the fraction  $\frac{128}{1-2}$ , or  $\frac{128}{-1}$ , or  $-128$ ; we should therefore have  $127-128$ , which is  $-1$ .

669. These properties must be therefore considered when for  $a$  numbers greater than unity are assumed. But when  $a$  is less than 1 the whole becomes more intelligible. Thus, let  $a=\frac{1}{2}$ , we then have  $\frac{1}{1-a}=\frac{1}{1-\frac{1}{2}}=\frac{1}{\frac{1}{2}}=2$ , which will be equal to the following series,  $1+\frac{1}{2}+\frac{1}{4}+\frac{1}{8}+\frac{1}{16}+\frac{1}{32}+\frac{1}{64}+\frac{1}{128}$ , &c. to infinity. Now, taking only two terms of this series, we have  $1+\frac{1}{2}$ , and it wants  $\frac{1}{2}$  that it may be equal to  $\frac{1}{1-a}=2$ . Take three terms, and it will want  $\frac{1}{4}$ , for the sum is then  $1\frac{3}{4}$ . Taking four terms, we have  $1\frac{7}{8}$ , and the deficiency is only  $\frac{1}{8}$ . Hence it is evident the more terms taken the less the difference becomes, and that if we continued on to infinity no difference would exist between the sum of the series and 2, the value of the fraction  $\frac{1}{1-a}$ .

670. Let  $a=\frac{1}{3}$ ; the fraction  $\frac{1}{1-a}$  will be  $=\frac{1}{1-\frac{1}{3}}=\frac{3}{2}=1\frac{1}{2}$ , which, reduced to an infinite series, becomes  $1+\frac{1}{3}+\frac{1}{9}+\frac{1}{27}+\frac{1}{81}+\frac{1}{243}$ , &c., and to which  $\frac{1}{1-a}$  is consequently equal. Taking two terms, we have  $1\frac{1}{3}$ ,  $\frac{1}{9}$  being still wanting. If three terms are taken, we have  $1\frac{4}{9}$ , and  $\frac{1}{27}$  will still be wanting. Four terms give us  $1\frac{13}{27}$ , and the difference is  $\frac{1}{34}$ . Since, then, the error continually becomes three times less, it will vanish at last.

671. Let  $a=\frac{2}{3}$ ; we shall have  $\frac{1}{1-a}=\frac{1}{1-\frac{2}{3}}=3$ , and the series is  $1+\frac{2}{3}+\frac{4}{9}+\frac{8}{27}+\frac{16}{81}+\frac{32}{243}$ , &c. Taking  $1\frac{2}{3}$ , the error is  $\frac{1}{3}$ ; if we take three terms, which are equal to  $2\frac{1}{3}$ , the error is  $\frac{2}{9}$ ; with four terms, or  $2\frac{11}{27}$ , the error is  $\frac{1}{27}$ .

672. If  $a=\frac{1}{4}$  the fraction is  $\frac{1}{1-\frac{1}{4}}=\frac{4}{3}=1\frac{1}{3}$ , and the series is  $1+\frac{1}{4}+\frac{1}{16}+\frac{1}{64}+\frac{1}{256}$ , &c. The two first terms  $=1+\frac{1}{4}$  give  $\frac{1}{12}$  for the error, and if we take one term more we have  $1\frac{5}{16}$ , or an error of only  $\frac{1}{48}$ .

673. In the same manner, the fraction  $\frac{1}{1+a}$  may be resolved into an infinite series by an actual division of the numerator 1 by the denominator  $1+a$ , as follows:—

$$\begin{array}{r}
 1+a) \overline{1} \quad (1-a+aa-a^3+a^5 \\
 \underline{1+a} \\
 -a \\
 \underline{-a-aa} \\
 aa \\
 \underline{aa+a^3} \\
 -a^3 \\
 \underline{-a^3-a^4} \\
 a^4 \\
 \underline{a^4+a^5} \\
 -a^5, \text{ \&c.}
 \end{array}$$

So that the fraction  $\frac{1}{1+a}$  is equal to the series  $1-a+aa-a^3+a^5-a^6-a^7$ , &c.

674. If  $a=1$ , we have the following singular result:  $\frac{1}{1+a}=\frac{1}{2}=1-1+1-1+1-1+1-1$ , &c. to infinity. The result appears contradictory, because, if we stop at  $-1$ , the series gives 0, and if we finish by  $+1$ , it gives 1. This, however, solves the difficulty, for as we must neither stop at  $-1$  nor  $+1$ , the sum can neither be 0 nor 1, but some quantity lying between these two, and therefore  $=\frac{1}{2}$ .

675. If we make  $a=\frac{1}{5}$ , the fraction will be  $\frac{1}{1+\frac{1}{5}}=\frac{5}{6}$ , which, consequently, expresses the value of the series,  $1-\frac{1}{5}+\frac{1}{4}-\frac{1}{8}+\frac{1}{16}-\frac{1}{32}+\frac{1}{64}$ , &c. to infinity. If we take only the two leading terms of this series, we have  $\frac{4}{5}$ , which is too small by  $\frac{1}{5}$ . If three terms be taken, we

$$\begin{array}{r}
 1-a+aa \quad 1 \quad (1+a-a^3-a^4+a^6+a^7, \&c. \\
 \hline
 1-a+aa \\
 a-aa \\
 \hline
 a-aa+a^3 \\
 \hline
 -a^3 \\
 \hline
 -a^3+a^4-a^5 \\
 \hline
 -a^4+a^5 \\
 \hline
 -a^4+a^5-a^6 \\
 \hline
 a^6 \\
 \hline
 a^6-a^7+a^8 \\
 \hline
 a^7-a^8 \\
 \hline
 a^7-a^8+a^9 \\
 \hline
 -a^9
 \end{array}$$

Hence we have the equation  $\frac{1}{1-a+aa} = 1 + a - a^3 - a^4 + a^6 + a^7 - a^9 - a^{10}$ , &c.; in which, if we make  $a=1$ , we have  $1=1+1-1+1+1-1+1+1$ , &c., which series contains twice that of  $1-1+1-1+1$ , &c. found above; and as that has been found equal to  $\frac{1}{2}$ , it is to be expected that we should find  $\frac{2}{3}$ , or 1 for the value of that just determined. If

$a=\frac{1}{2}$  we shall have the equation  $\frac{1}{1-a+aa} = 1\frac{1}{2} - \frac{1}{8} - \frac{1}{16} + \frac{1}{64} - \frac{1}{128} + \frac{1}{256}$ , &c. If  $a=\frac{1}{3}$  we shall have the equation  $\frac{1}{1-a+aa} = 1 + \frac{1}{3} - \frac{1}{27} - \frac{1}{81} + \frac{1}{729}$ , &c., of which series, if the four leading terms be taken, we have  $\frac{109}{81}$ , which is only  $\frac{1}{387}$  less than  $\frac{2}{3}$ . Again, if  $a=\frac{2}{3}$ , we have  $\frac{1}{1-a+aa} = 1 + \frac{2}{3} - \frac{8}{27} - \frac{16}{81} + \frac{64}{729}$ , &c., a series which is equal to the preceding one, and subtracting one from the other,  $\frac{1}{3} - \frac{2}{27} - \frac{16}{81} + \frac{64}{729}$ , &c. must = 0. The four terms added together make  $-\frac{2}{81}$ .

679. The method of resolving generally all fractions into infinite series which has been above given, is often of great utility, and though it never ceases, an infinite series may have a determinate value. Many discoveries of the highest importance have been derived from this branch of mathematics, which, on that account, well deserves the study and comprehension of the reader.

#### THE SQUARES OF COMPOUND QUANTITIES.

680. To find the square of a compound quantity, it is only necessary to multiply by itself, and it is the square required; thus the square of  $a+b$  is found in the following manner:—

$$\begin{array}{r}
 a+b \\
 a+b \\
 \hline
 aa+ab \\
 ab+bb \\
 \hline
 aa+2ab+bb
 \end{array}$$

From which we learn that the square of any number comprising two terms consists, first, of the squares of each term, namely  $aa$  and  $bb$ , and twice the product of the two terms, that is  $2ab$ . In figures, suppose  $a=12$  and  $b=4$ , that is, let it be required to find the square of 16, we have  $144+96+16$ , or 256. This formula then gives us the power of finding the squares of numbers, however great, if we divide them into two parts. Thus, to find the square of 49, recollecting that this number is equal to  $40+9$ , its square is  $=1600+720+81=2401$ . From the same cause it is evident that the square of  $a+1$  will be  $aa+2a+1$ ; and since the square of  $a$  is  $aa$ , we find the square of  $a+1$  by adding to it  $2a+1$ , wherein it is observable that this  $2a+1$  is the sum of the two roots  $a$  and  $a+1$ . Hence, the square of 10 being 100, that of 11 will be  $100+21$  (that is,  $100+2 \times 10+1$ ). The square of 49 being 2401, that of 50 is  $2401+99=2500$ ; the square of 50 being 2500, that of 51  $=2500+101=2601$ , &c.

681. The square of a compound quantity, as  $a+b$ , is thus represented  $(a+b)^2$ . We have then  $(a+b)^2=aa+2ab+bb$ , whence result the following equations:—

$$\begin{array}{l}
 (a+1)^2=aa+2a+1; \quad (a+2)^2=aa+4a+4; \quad (a+3)^2=aa+6a+9; \\
 (a+4)^2=aa+8a+16, \&c.
 \end{array}$$

682. If the root is  $a-b$ , the square of it is  $aa-2ab+bb$ , which also contains the squares of the two terms, but in such a manner, that from their sum must be taken twice the product of those terms; thus, let  $a=10$  and  $b=-1$ , the square of 9 will be found to be  $100-20+1=81$ .

683. Having then the equation  $(a-b)^2 = aa - 2ab + bb$ , we shall have  $(a-1)^2 = aa - 2a + 1$ . From which it is evident that the square of  $a-1$  is found by subtracting from  $aa$  the sum of the two roots  $a$  and  $a-1$ , that is,  $2a-1$ . Let  $a=50$ , then  $aa=2500$ ; and  $a-1=49$ ; hence  $49^2 = 2500 - 99 = 2401$ .

684. The rule is moreover confirmed and illustrated by fractions; for, taking as the root  $\frac{2}{3} + \frac{2}{3}$  (which make 1), the square will be

$$\frac{9}{25} + \frac{4}{25} + \frac{12}{25} = \frac{25}{25}, \text{ that is, } 1.$$

And further, the square of  $\frac{1}{2} - \frac{1}{2}$  (or of  $\frac{1}{2}$ ) will be  $\frac{1}{4} - \frac{1}{2} + \frac{1}{4} = \frac{0}{4}$ .

685. If the root consists of a greater number of terms, the square is determined in a similar manner; take, for instance, the square of  $a+b+c$ .

$$\begin{array}{r} a+b+c \\ a+b+c \\ \hline aa+ab+ac \quad +bc \\ \quad ab+ac \quad +bb+bc+cc \\ \hline aa+2ab+2ac+bb+2bc+cc \end{array}$$

686. It will be perceived that the product includes the square of each term of the roots, and, besides that, the double products of those terms multiplied two by two. To exhibit this in figures, divide the number 345 into three parts,  $300+40+5$ ; its square will then be composed of the following parts:—

$$\begin{array}{r} 345 \\ 345 \\ \hline 90000 = 300^2 \\ 1600 = 40^2 \\ 25 = 5^2 \\ 24000 = 2 \times 300 \times 40 \\ 3000 = 2 \times 300 \times 5 \\ 400 = 2 \times 40 \times 5 \\ \hline 119025 \end{array}$$

119025, which is equal to the product of  $345 \times 345$ .

687. Though some of the terms of the root be negative, the rule still holds good, only that we must be careful in prefixing the signs to the double products. For instance, the square of  $a-b-c$  being  $aa+bb+cc-2ab-2ac+2bc$ , if the number 345 be represented by  $400-50-5$ , we shall have

Positive parts.	Negative parts.
+ 160000	- 40000
2500	4000
500	
25	- 44000
+ 163025	
- 44000	
<hr/> 119025	

119025, the square of 345, as before.

#### EXTRACTION OF ROOTS OF COMPOUND QUANTITIES.

688. For the extraction of the roots of compound quantities, and the rule by which the operation is guided, we must consider with attention the square of the root  $a+b$ , which is  $aa+2ab+bb$ . It will be seen that it is composed of several terms; and that, therefore, the root will comprise more than one term, and that if the square be written so that the powers of one of the letters, as  $a$ , may continually diminish, the first term will be the first square of the root; and as, in the instance adduced, the first term of the square is  $aa$ , it is certain that the first term of the root is  $a$ . Having thus found the first term of the root, that is,  $a$ , we have to consider the rest of the square, namely  $2ab+bb$ , and endeavour to ascertain from it the second part of the root, which is  $b$ . Now as the remainder  $2ab+bb$ , which may be represented by the product  $(2a+b)b$ , has two factors,  $2a+b$  and  $b$ , it is evident that the latter  $b$ , which is the second part of the root, will be found by dividing the remainder  $2ab+bb$  by  $2a+b$ . The quotient then arising from the division of the above remainder by  $2a+b$ , is the second term of the root required. In the division, it is to be observed that  $2a$  is the double of the first term  $a$ , which is already determined, and as the second term is yet unknown, though for the present its place must be left empty, the division may be attempted, since in it we attend only to the first term  $2a$ . When, however, the quotient is found, which is here  $b$ , it must be put in the empty place, by which the division is rendered complete. The operation is thus represented:—

$$\begin{array}{r}
 aa + 2ab + bb \ (a + b) \\
 aa \\
 \hline
 2a + b) \ 2ab + bb \\
 \underline{2ab + bb} \\
 0
 \end{array}$$

689. In a similar manner may be found the square root of other compound quantities, provided they are squares, as may be seen by the following examples.

$$\begin{array}{lll}
 \text{(I.) } aa + 6ab + 9bb \ (a + 3b) & \text{(II.) } 4aa - 4ab + bb \ (2a - b) & \text{(III.) } 9pp + 24pq + 16qq \ (3p + 4q) \\
 aa & 4aa & 9pp \\
 \hline
 2a + 3b) \ 6ab + 9bb & 4a - b) \ -4ab + bb & 6p + 4q) \ 24pq + 16qq \\
 \underline{6ab + 9bb} & \underline{-4ab + bb} & \underline{24pq + 16qq} \\
 0 & 0 & 0
 \end{array}$$

$$\begin{array}{r}
 \text{(IV.) } 25xx - 60x + 36 \ (5x - 6) \\
 25xx \\
 \hline
 10x - 6) \ -60x + 36 \\
 \underline{-60x + 36} \\
 0
 \end{array}$$

690. If a remainder occurs after division, it proves that the root is composed of more than two terms. In which case, the two terms already found are considered as forming the first part, and we must try to obtain the other from the remainder in the same manner as the second part of the root was found. The following examples will show the mode of operation.

$$\begin{array}{ll}
 \text{(I.) } aa + 2ab - 2ac - 2bc + bb + cc \ (a + b + c) & \text{(II.) } a^4 + 2a^3 + 3aa + 2a + 1 \ (aa + a + 1) \\
 aa & a^4 \\
 \hline
 2a + b) \ 2ab - 2ac - 2bc + bb + cc & 2aa + a) \ 2a^3 + 3aa \\
 \underline{2ab} & \underline{2a^3 + aa} \\
 2a + b - c) \ -2ac - 2bc + cc & 2aa + 2a + 1) \ 2aa + 2a + 1 \\
 \underline{-2ac - 2bc + cc} & \underline{2aa + 2a + 1} \\
 0 & 0
 \end{array}$$

$$\begin{array}{l}
 \text{(III.) } a^6 - 6a^5b + 15a^4bb - 20a^3b^3 + 15aab^4 - 6ab^5 + b^6 \ (a^3 - 3aab + 3abb - b^3) \\
 a^6 \\
 \hline
 2a^3 - 3aab) \ -6a^5b + 15a^4bb \\
 \underline{-6a^5b + 9a^4bb} \\
 2a^3 - 6aab + 3abb) \ 6a^4bb - 20a^3b^3 + 15aab^4 \\
 \underline{6a^4bb - 18a^3b^3 + 9aab^4} \\
 2a^3 - 6aab + 6abb - b^3) \ -2a^3b^3 + 6aab^4 - 6ab^5 + b^6 \\
 \underline{-2a^3b^3 + 6aab^4 - 6ab^5 + b^6} \\
 0
 \end{array}$$

691. From this method of extracting the square root, it is easy to deduce the rule given for that purpose in common books of arithmetic; as in the following examples in numbers.

$$\begin{array}{llll}
 \begin{array}{r}
 529(23 \\
 4 \\
 \hline
 43)129 \\
 129 \\
 \hline
 0
 \end{array} &
 \begin{array}{r}
 9409(97 \\
 81 \\
 \hline
 187)1309 \\
 1309 \\
 \hline
 0
 \end{array} &
 \begin{array}{r}
 15129(123 \\
 1 \\
 \hline
 22) \ 51 \\
 44 \\
 \hline
 243) \ 729 \\
 729 \\
 \hline
 0
 \end{array} &
 \begin{array}{r}
 1522756(1234 \\
 1 \\
 \hline
 2\cdot2) \ 52 \\
 44 \\
 \hline
 243) \ 827 \\
 729 \\
 \hline
 2464) \ 9856 \\
 9856 \\
 \hline
 0
 \end{array}
 \end{array}$$

692. If there be a remainder after the whole operation, it proves that the number is not an exact square, and therefore its root cannot be assigned. When this is the case, the radical sign before mentioned must be written before the quantity, and the quantity itself is placed between parentheses, or under a line. Thus, the square root of  $aa + bb$  is represented by

$\sqrt{(aa+bb)}$ , or by  $\sqrt{aa+bb}$ , and  $\sqrt{(1-xx)}$  or  $\sqrt{1-xx}$  expresses the square root of  $1-xx$ . Instead of the radical sign the fractional exponent  $\frac{1}{2}$  may be used, thus  $(aa+bb)^{\frac{1}{2}}$  to  $aa+bb$   $^{-\frac{1}{2}}$  equally represent the square root of  $aa+bb$ .

CALCULATION OF IRRATIONAL QUANTITIES.

693. The addition of two or more irrational quantities is performed by writing all the terms in succession, each with its proper sign. They may often be abbreviated thus: for  $\sqrt{a} + \sqrt{a}$  we may write  $2\sqrt{a}$ , and  $\sqrt{a} - \sqrt{a} = 0$ , because the terms destroy one another. Thus the quantities  $3 + \sqrt{2}$  and  $1 + \sqrt{2}$  added together, make  $4 + 2\sqrt{2}$  or (590.)  $4 + \sqrt{8}$ . The sum of  $5 + \sqrt{3}$  and  $4 - \sqrt{3}$  is 9, and that of  $2\sqrt{3} + 3\sqrt{2}$  and  $\sqrt{3} - \sqrt{2}$  is  $3\sqrt{3} + 2\sqrt{2}$ .

694. Subtraction is equally simple, since we have only to change the signs of the numbers to be subtracted, and then add them together, thus:—

$$\begin{array}{r} \text{Subtract from } 4 - \sqrt{2} + 2\sqrt{3} - 3\sqrt{5} + 4\sqrt{6} \\ \text{The numbers } 1 + 2\sqrt{2} - 2\sqrt{3} - 5\sqrt{5} + 6\sqrt{4} \\ \hline 3 - 3\sqrt{3} + 4\sqrt{3} + 2\sqrt{5} + 2\sqrt{6} \end{array}$$

695. In multiplication it must be remembered that  $\sqrt{a}$  multiplied by  $\sqrt{a}$  produces  $a$ , and that if the numbers which follow the sign  $\sqrt{\phantom{a}}$  are different, as  $a$  and  $b$ , we have  $\sqrt{ab}$  for the product of  $\sqrt{a}$  multiplied by  $\sqrt{b}$ . From due observance of this, the following examples are easily calculated.

$$\begin{array}{r} 1 + \sqrt{2} \\ 1 + \sqrt{2} \\ \hline 1 + \sqrt{2} \\ + \sqrt{2} + 2 \\ \hline 1 + 2\sqrt{2} + 2 = 3 + 2\sqrt{2} \end{array} \qquad \begin{array}{r} 4 + 2\sqrt{2} \\ 2 - \sqrt{2} \\ \hline 8 + 4\sqrt{2} \\ - 4\sqrt{2} - 4 \\ \hline 8 - 4 = 4 \end{array}$$

The rules apply also to imaginary quantities, and it will only be necessary to mention that  $\sqrt{-a}$  multiplied by  $\sqrt{-a}$  produces  $-a$ .

696. To find the cube of  $-1 + \sqrt{-3}$ , we take the square of that number, and multiply such square by the number, as follows:—

$$\begin{array}{r} -1 + \sqrt{-3} \\ -1 + \sqrt{-3} \\ \hline 1 - \sqrt{-3} \\ - \sqrt{-3} - 3 \\ \hline 1 - 2\sqrt{-3} - 3 = -2 - 2\sqrt{-3} \\ -1 + \sqrt{-3} \\ \hline 2 + 2\sqrt{-3} \\ -2\sqrt{-3} + 6 \\ \hline 2 + 6 = 8 \end{array}$$

697. To divide surds, we have only to express the quantity in the form of a fraction, which may then be changed into another expression having a rational denominator. Thus, for instance, if the denominator be  $a + \sqrt{b}$ , and it as well as the numerator be multiplied by  $a - \sqrt{b}$ , the new denominator will be  $aa - b$ , in which no radical sign occurs. Let it, then, be required to divide  $3 + 2\sqrt{2}$  by  $1 + \sqrt{2}$ , we have  $\frac{3+2\sqrt{2}}{1+\sqrt{2}}$ . Multiplying both terms of the fraction by  $1 - \sqrt{2}$ , we have for the numerator, —

$$\begin{array}{r} 3 + 2\sqrt{2} \\ 1 - \sqrt{2} \\ \hline 3 + 2\sqrt{2} \\ - 3\sqrt{2} - 4 \\ \hline 3 - \sqrt{2} - 4 = -\sqrt{2} - 1; \end{array}$$

and for the denominator, —

$$\begin{array}{r} 1 + \sqrt{2} \\ 1 - \sqrt{2} \\ \hline 1 + \sqrt{2} \\ - \sqrt{2} - 2 \\ \hline 1 - 2 = -1. \end{array}$$

The new fraction is therefore  $\frac{\sqrt{2}-1}{-1}$ ; and if the terms be again multiplied by  $-1$ , we shall have for the numerator  $\sqrt{2}+1$ , and  $+1$  for the denominator. It is easy to show that  $\sqrt{2}+1$  is equal to the proposed fraction  $\frac{3+2\sqrt{2}}{1+\sqrt{2}}$ ; for  $\sqrt{2}+1$  being multiplied by the divisor  $1+\sqrt{2}$ , thus —

$$\begin{array}{r} 1 + \sqrt{2} \\ 1 + \sqrt{2} \\ \hline 1 + \sqrt{2} \\ + \sqrt{2} + 2 \end{array}$$

we have  $1 + 2\sqrt{2} + 2 = 3 + 2\sqrt{2}$ .

698. Fractions may be transformed into others which have rational denominators. Thus, in the fraction  $\frac{1}{5-2\sqrt{6}}$ , by multiplying both numerator and denominator by  $5+2\sqrt{6}$ , it becomes  $\frac{5+2\sqrt{6}}{1} = 5 + 2\sqrt{6}$ . When the denominator contains several terms, the radical signs may, in the same manner, be made to vanish one by one. Thus, in the fraction  $\frac{1}{\sqrt{10}-\sqrt{2}-\sqrt{3}}$ , the two terms may be multiplied by  $\sqrt{10}+\sqrt{2}+\sqrt{3}$ , by which is obtained the fraction  $\frac{\sqrt{10}+\sqrt{2}+\sqrt{3}}{5-2\sqrt{6}}$ . Then, multiplying its numerator and denominator by  $5+2\sqrt{6}$ , we have  $5\sqrt{10}+11\sqrt{2}+9\sqrt{3}+2\sqrt{60}$ .

#### OF CUBES, AND THE EXTRACTION OF THEIR ROOTS.

699. The cube of a root  $a+b$  is found by multiplying its square  $aa+2ab+bb$  again by  $a+b$ , thus: —

$$\begin{array}{r} aa+2ab+bb \\ a+b \\ \hline a^3+2aab+abb \\ aab+2abb+b^3 \\ \hline a^3+3aab+3abb+b^3 = \text{to the cube of } a+b. \end{array}$$

The cube, then, contains the cubes of the two parts of the root, and, besides that,  $3aab+3abb$ , a quantity equal to  $(3ab) \times (a+b)$ , that is, the triple product of the two parts  $a$  and  $b$  multiplied by their sum. From which we learn, that when a root is composed of two terms, its cube is easily found. Thus, the number  $5=3+2$ ; its cube, therefore, is  $27+8+18 \times 5=125$ .

700. When the cube, as  $a^3+3aab+3abb+b^3$ , is given to find the root, the following is the process, the cube being arranged according to the powers of one letter. By the first term  $a^3$  we perceive that  $a$ , whose cube is  $a^3$ , is the first term of the root; if, then, that cube be subtracted from the cube proposed, the remainder,  $3aab+3abb+b^3$ , will furnish the second term of the root. Now, knowing that the second term is  $+b$ , our object is to find how it may be derived from the above remainder. This remainder may be expressed by two factors, — namely,  $(3aa+3ab+bb) \times (b)$ ; if, therefore, we divide by the first of them, we obtain  $+b$ , the second part of the root required.

701. But the second term, as well as the divisor, are supposed to be unknown; we know, however, the first term of that divisor, — that is,  $3aa$ , or thrice the square of the first term, already found; and that is sufficient, for by that it is easy to find the other part  $b$ , and then complete the divisor before performing the division. For this purpose we must join to  $3aa$  thrice the product of the two terms, or  $3ab$  and  $bb$ , or the square of the second term of the root. We subjoin two examples: —

$$(I.) \begin{array}{r} a^3+12aa+48a+64(a+4) \\ a^3 \end{array}$$

$$\begin{array}{r} 3aa+12a+16)12aa+48a+64 \\ 12aa+48a+64 \\ \hline 0 \end{array}$$

$$(II.) \begin{array}{r} a^6-6a^5+15a^4-20a^3+15a^2-6a+1(aa-2a+1) \\ a^6 \end{array}$$

$$\begin{array}{r} 3a^4-6a^3+4aa) -6a^5+15a^4-20a^3 \\ -6a^5+12a^4-8a^3 \end{array}$$

$$\begin{array}{r} 3a^4-12a^3+12aa+3a^2-6a+1) 3a^4-12a^3+15a^2-6a+1 \\ 3a^4-12a^3+15a^2-6a+1 \\ \hline 0 \end{array}$$

On this analysis is founded the common rule for the extraction in numbers of the cube root. Take, for example, the number 4096.

$$\begin{array}{r}
 \begin{array}{rcl}
 & & 4096(10+6=16 \\
 & & 1000 \\
 3 \text{ times } 10^2 & = & 300 \\
 3 \text{ times } 10 \times 6 & = & 180 \\
 6^2 \text{ (second term)} & = & 36 \\
 \hline
 & 516 & \\
 \hline
 \end{array}
 \begin{array}{r}
 3096 \\
 3096 \\
 \hline
 0
 \end{array}
 \end{array}$$

We will further extract the cube root of 82881856.

$$\begin{array}{r}
 \begin{array}{rcl}
 & & 82881856(400+30+6 \\
 & & 64000000 \\
 3 \text{ times } 400^2 & - & = 480000 \\
 3 \text{ times } 400 \times 30 & - & = 36000 \\
 30^2 \text{ (square of second term)} & = & 900 \\
 \hline
 & 516900 & \\
 3 \text{ times } 430^2 & - & = 554700 \\
 3 \text{ times } 430 \times 6 & - & = 7740 \\
 6^2 \text{ (square of third term)} & = & 36 \\
 \hline
 & 562476 & \\
 \hline
 \end{array}
 \begin{array}{r}
 18881856 \\
 15502000 \\
 \hline
 13374856 \\
 \hline
 13374856 \\
 \hline
 0
 \end{array}
 \end{array}$$

THE HIGHER POWERS OF COMPOUND QUANTITIES.

702. Powers of a greater number of degrees than squares and cubes are now to be considered. We have already explained the method in which they are represented by exponents. It will be found convenient to keep in mind that, in dealing with a compound root, it is inclosed in a parenthesis. For instance,  $(a+b)^4$  signifies that  $a+b$  is to be raised to the fourth power or degree, and that  $(a-b)^7$  expresses the seventh power of  $a-b$ ; the subject of this section is to explain the nature of these powers, in which some peculiarities will be noticed.

703. If the root or first power be  $a+b$ , all the higher powers will be found by multiplying the last power found again by the root, as in the following example: —

$$\begin{array}{l}
 (a+b)^1 = a+b \\
 \quad \quad \quad a+b \\
 \quad \quad \quad \hline
 \quad \quad aa+ab \\
 \quad \quad \quad \quad + ab+bb \\
 \quad \quad \quad \quad \hline
 (a+b)^2 = aa+2ab+bb \\
 \quad \quad \quad a+b \\
 \quad \quad \quad \hline
 \quad \quad a^3+2aab+abb \\
 \quad \quad \quad \quad + aab+2abb+b^3 \\
 \quad \quad \quad \quad \hline
 (a+b)^3 = a^3+3aab+3abb+b^3 \\
 \quad \quad \quad a+b \\
 \quad \quad \quad \hline
 \quad \quad a^4+3a^3b+3aabb+ab^3 \\
 \quad \quad \quad \quad + a^3b+3aabb+3ab^2+b^4 \\
 \quad \quad \quad \quad \hline
 (a+b)^4 = a^4+4a^3b+6aabb+4ab^3+b^4 \\
 \quad \quad \quad a+b \\
 \quad \quad \quad \hline
 \quad \quad a^5+4a^4b+6a^3bb+4aab^3+ab^4 \\
 \quad \quad \quad \quad + a^3b+4a^3bb+6aab^3+4ab^4+b^5 \\
 \quad \quad \quad \quad \hline
 (a+b)^5 = a^5+5a^4b+10a^3bb+10aab^3+5ab^4+b^5 \\
 \quad \quad \quad a+b \\
 \quad \quad \quad \hline
 \quad \quad a^6+5a^5b+10a^4bb+10a^3b^3+5a^2b^4+ab^5 \\
 \quad \quad \quad \quad + a^5b+5a^4bb+10a^3b^3+10a^2b^4+5ab^5+b^6 \\
 \quad \quad \quad \quad \hline
 (a+b)^6 = a^6+6a^5b+15a^4bb+20a^3b^3+15a^2b^4+6ab^5+b^6, \&c.
 \end{array}$$

704. In a similar manner are found the powers of the root  $a-b$ , the only difference being that the even or 2d, 4th, 6th, &c. terms will be found to be affected by the sign minus.

$$\begin{aligned}
 (a-b)^1 &= \frac{a-b}{a-b} \\
 (a-b)^2 &= \frac{aa-2ab+bb}{a-b} \\
 (a-b)^3 &= \frac{a^3-3aab+3abb-b^3}{a-b} \\
 (a-b)^4 &= \frac{a^4-4a^3b+6a^2bb-4ab^3+b^4}{a-b} \\
 (a-b)^5 &= \frac{a^5-5a^4b+10a^3bb-10a^2b^3+5ab^4-b^5}{a-b} \\
 (a-b)^6 &= \frac{a^6-6a^5b+15a^4bb-20a^3b^3+15aab^4-6ab^5+b^6}{a-b}
 \end{aligned}$$

705. In this last example all the odd powers of  $b$  have the sign  $-$ , while the even powers retain the sign  $+$ . The reason is, that the powers of that letter ascend in the following series,  $-b, +bb, -b^3, +b^4, -b^5, +b^6$ , &c., which sufficiently indicates that the even powers must be affected by the sign  $+$ , and the odd ones by the sign  $-$ . The labour of the calculation being considerable, it is important to find a mode of performing the operation in an abridged manner. Now, if in the powers above determined we take away the numbers, or *coefficients* preceding each term, we shall observe the following order: first, in each succeeding term the powers of  $a$  decrease by unity, whereas the powers of  $b$  increase in the same proportion, so that the sum of the exponents of  $a$  and  $b$  is always the same, and always equal to the power of the exponent required; and, lastly, we find the term  $b$  by itself raised to the same power. Hence we know that if the tenth power of  $b$  were required, the terms without their coefficients would stand in the following order:  $a^{10}, a^9b, a^8b^2, a^7b^3, a^6b^4, a^5b^5, a^4b^6, a^3b^7, a^2b^8, ab^9, b^{10}$ . To determine the coefficients or numbers by which these are to be multiplied, we may observe that, with regard to the first term, its coefficient is always unity; and that, in respect of the second, its coefficient is always the exponent of the power; but the order of the other coefficients is not so manifest, though there is a law by which they are governed, which the following table will show.

Powers.	Coefficients.				Sum of the coefficients.			
I	-	-	-	1, 1	-	-	-	2 = 2 <sup>1</sup>
II	-	-	-	1, 2, 1	-	-	-	4 = 2 <sup>2</sup>
III	-	-	-	1, 3, 3, 1	-	-	-	8 = 2 <sup>3</sup>
IV	-	-	-	1, 4, 6, 4, 1	-	-	-	16 = 2 <sup>4</sup>
V	-	-	-	1, 5, 10, 10, 5, 1	-	-	-	32 = 2 <sup>5</sup>
VI	-	-	-	1, 6, 15, 20, 15, 6, 1	-	-	-	64 = 2 <sup>6</sup>
VII	-	-	-	1, 7, 21, 35, 35, 21, 7, 1	-	-	-	128 = 2 <sup>7</sup>
VIII	-	-	-	1, 8, 28, 56, 70, 56, 28, 8, 1	-	-	-	256 = 2 <sup>8</sup>
IX	-	-	-	1, 9, 36, 84, 126, 126, 84, 36, 9, 1	-	-	-	512 = 2 <sup>9</sup>
X	-	-	-	1, 10, 45, 120, 210, 252, 210, 120, 45, 10, 1	-	-	-	1024 = 2 <sup>10</sup>

From which we may see that the tenth power of  $a+b$  will be  $a^{10}+10a^9b+45a^8b^2+120a^7b^3+210a^6b^4+252a^5b^5+210a^4b^6+120a^3b^7+45a^2b^8+10ab^9+b^{10}$ .

706. The sum of the coefficients in each power is equal to the number 2 raised to the same power, as will be seen by reference to the above table, and they increase from the beginning to the middle, and then decrease in the same order. In the even powers the greatest coefficients are exactly in the middle, but in the odd powers two coefficients equal and greater than the others are found in the middle belonging to the mean terms. We shall hereafter touch upon the reason of the following rule for determining the coefficients

in all powers proposed. Let the power proposed be the seventh, then placing the exponent of the power as the numerator, and letting the denominator follow in the natural order of the numbers 1, 2, 3, 4, &c., we have the following fractions,  $\frac{7}{1}, \frac{6}{2}, \frac{5}{3}, \frac{4}{4}, \frac{3}{5}, \frac{2}{6}, \frac{1}{7}$ . Now, as the first coefficient is always 1, the first fraction gives the second coefficient, the product of the two first fractions multiplied together gives the third coefficient, the product of the three first fractions represents the fourth coefficient, and so on; thus, for instance, the fifth coefficient will be the product of  $\frac{7}{1} \times \frac{6}{2} \times \frac{5}{3} \times \frac{4}{4} = 35$ , &c. This rule renders it unnecessary to find the preceding coefficients, and enables us to discover immediately the coefficients which belong to any power; and we can, by its aid, express any power of  $a + b$  however high; thus, the hundredth power of  $a + b$ , will be  $(a + b)^{100} = a^{100} + \frac{100}{1} \times a^{99}b + \frac{100 \times 99}{1 \times 2} + a^{98}b^2 + \frac{100 \times 99 \times 98}{1 \times 2 \times 3} a^{97}b^3 + \frac{100 \times 99 \times 98 \times 97}{1 \times 2 \times 3 \times 4} a^{96}b^4 +$ , &c.; from which the law of the preceding terms is evident.

#### ON THE TRANSPOSITION OF LETTERS, WHEREON THE LAST RULE RESTS.

707. In the coefficients we have just been considering it will be found that each term is presented as many times as the letters whereof the term consists can be transposed; or, in other words, the coefficient of each term is equal to the number of transpositions that its letters admit. Thus, in the second power the term  $ba$  is taken twice, that is to say, its coefficient is 2, for the order of its letters  $ab$  or  $ba$  can be changed only twice. The term  $aa$ , whose letters can undergo no change, is hence only found once. In the third power of  $a + b$  the term  $aab$  can be written in three different ways,  $aab, aba, baa$ , and here the coefficient is 3. In the fourth power the coefficient of  $a^3b$  must be 4, because  $aaab$  admits of four different arrangements,  $aaab, aaba, abaa, baaa$ , and so on. It thence becomes desirable to know in how many different ways a given number of different letters may be arranged. Now, beginning with the simplest case, namely,  $a$  and  $b$ , we see at a glance that only two transpositions, namely  $ab$  and  $ba$ , can take place. If we have three letters, we see that each of the three may take the first place, while the two others admit of two transpositions. Thus, making  $a$  the first letter, we have  $abc, acb$ ; if  $b$  is the first, we have  $bac, bca$ ; but if  $c$  is made the first, we have  $cab, cba$ . Hence the whole number of arrangements is  $3 \times 2 = 6$ . If four letters,  $abcd$ , occur, each may be placed first, and we know the three others are capable of six different arrangements; hence the whole number of transpositions is  $4 \times 6 = 24$ , or  $4 \times 3 \times 2 \times 1$ . If the number of letters be five, we have  $5 \times 24 = 120$ , or  $5 \times 4 \times 3 \times 2 \times 1$ . Whatever, then, the number of letters, provided they be different, the number of transpositions is easily determined, and, up to the number ten, are subjoined in the following table:—

Number of letters.	Number of transpositions.
I - - - -	- - - - 1 = 1
II - - - -	- - - - 2 $\times$ 1 = 2
III - - - -	- - - - 3 $\times$ 2 $\times$ 1 = 6
IV - - - -	- - - - 4 $\times$ 3 $\times$ 2 $\times$ 1 = 24
V - - - -	- - - - 5 $\times$ 4 $\times$ 3 $\times$ 2 $\times$ 1 = 120
VI - - - -	- - - - 6 $\times$ 5 $\times$ 4 $\times$ 3 $\times$ 2 $\times$ 1 = 720
VII - - - -	- - - - 7 $\times$ 6 $\times$ 5 $\times$ 4 $\times$ 3 $\times$ 2 $\times$ 1 = 5040
VIII - - - -	- - - - 8 $\times$ 7 $\times$ 6 $\times$ 5 $\times$ 4 $\times$ 3 $\times$ 2 $\times$ 1 = 40320
IX - - - -	- - - - 9 $\times$ 8 $\times$ 7 $\times$ 6 $\times$ 5 $\times$ 4 $\times$ 3 $\times$ 2 $\times$ 1 = 362880
X - - - -	- - - - 10 $\times$ 9 $\times$ 8 $\times$ 7 $\times$ 6 $\times$ 5 $\times$ 4 $\times$ 3 $\times$ 2 $\times$ 1 = 3628800

The numbers, however, in this table can only be used when the letters are all different; and if two or more of them are alike, the number of transpositions becomes much less; as, if the letters were all alike, there could be but one arrangement. Our next object, then, will be to find how the numbers in the table diminish from similarity of letters. We have seen that when two similar letters occur, only one arrangement can be made, consequently the number above found is reduced one half, or must be divided by 2. If these letters are alike, the six transpositions are reduced to one, whence the number in the table must be divided by  $6 = 3 \times 2 \times 1$ . And, in the same way, when four letters are alike, we must divide the number in the table by  $24 = 4 \times 3 \times 2 \times 1$ , &c.

708. Thus there is no difficulty in ascertaining the number of transpositions the letters  $aaabbc$  may undergo; for, if they were all different, they would admit of  $6 \times 5 \times 4 \times 3 \times 2 \times 1$  transpositions. But as  $a$  occurs three times, we must divide the number of transpositions by  $3 \times 2 \times 1$ ; and as  $b$  occurs twice, we must again divide by  $2 \times 1$ ; the numbers required, therefore, will be  $\frac{6 \times 5 \times 4 \times 3 \times 2 \times 1}{3 \times 2 \times 1 \times 2 \times 1} = 5 \times 4 \times 3 = 60$ .

709. We shall now apply the rule in the example of the seventh power of  $a + b$ , or  $(a + b)^7$ . The first term is  $a^7$ , which only occurs once; and, as all the other terms have seven letters, the number of transpositions for each term would be  $7 \times 6 \times 5 \times 4 \times 3 \times 2 \times 1$  if the letters were all different. But the second term  $a^6b$  contains six letters alike, hence

the product last mentioned must be divided by  $6 \times 5 \times 4 \times 3 \times 2 \times 1$ , whence the coefficient will be  $\frac{7 \times 6 \times 5 \times 4 \times 3 \times 2 \times 1}{6 \times 5 \times 4 \times 3 \times 2 \times 1} = \frac{5040}{720} = 7$  or 7.

710. In the third term  $a^5bb$ , the same letter  $a$  occurs five times and the same letter  $b$  twice, the total number of letters being seven all through the power. We have here, then, to divide the number which seven transpositions give by  $5 \times 4 \times 3 \times 2 \times 1$ , and then by  $2 \times 1$ , whence we have the coefficient  $= \frac{7 \times 6 \times 5 \times 4 \times 3 \times 2 \times 1}{5 \times 4 \times 3 \times 2 \times 1 \times 2 \times 1} = \frac{5040}{240} = 21$  or 21. It will be unnecessary to proceed with the remaining terms, the mode of finding the coefficient must be obvious. From what has been already said we shall find that the above rule enables us to find all the powers of roots consisting of more than two terms. Let us, for instance, apply them to the third power of  $a + b + c$ , the terms whereof must be formed by all the possible combinations of the three letters, each term having for its coefficient the number of its transpositions as above. The third power of  $a + b + c$  will be found by multiplication to be  $a^3 + 3aab + 3aac + 3abb + 3abc + 3acc + b^3 + 3bb + 3bcc + c^3$ .

711. Now, suppose  $a=1$ ,  $b=1$ ,  $c=1$ , the cube of  $1+1+1$  or 3 will be  $1+3+3+3+6+3+1+3+3+1=27$ , and the rule is thereby confirmed.

#### THE EXPRESSION OF IRRATIONAL POWERS BY INFINITE SERIES.

712. If we had supposed  $a=1$ ,  $b=1$ , and  $c=-1$ , we should have found for the cube of  $1+1-1$ , that is, of  $1+3-3+3-6+3+1-3+3-1=1$ .

713. In subsection 705. we have shown the method of finding any power of  $a+b$ . Suppose the exponent undetermined, but expressed by  $n$ , we shall have the rule there laid down—

$$(a+b)^n = a^n + \frac{n}{1} a^{n-1} b + \frac{n}{1} \times \frac{n-1}{2} a^{n-2} b^2 + \frac{n}{1} \times \frac{n-1}{2} \times \frac{n-2}{3} a^{n-3} b^3 + \frac{n}{1} \times \frac{n-1}{2} \times \frac{n-2}{3} \times \frac{n-3}{4} a^{n-4} b^4 + \&c.$$

If the same power of the root  $a-b$  were required, we should have only to change the signs of the even terms, and should have

$$(a-b)^n = a^n - \frac{n}{1} a^{n-1} b + \frac{n}{1} \times \frac{n-1}{2} a^{n-2} b^2 - \frac{n}{1} \times \frac{n-1}{2} \times \frac{n-2}{3} a^{n-3} b^3 + \frac{n}{1} \times \frac{n-1}{2} \times \frac{n-2}{3} \times \frac{n-3}{4} a^{n-4} b^4, \&c.$$

714. These formulæ are useful from the facility they afford in expressing all kinds of radicals. It has already been seen that all irrational quantities may assume the form of powers whose exponents are fractional, and that  $\sqrt[n]{a} = a^{\frac{1}{n}}$ ;  $\sqrt[n]{a} = a^{\frac{1}{n}}$ ; and  $\sqrt[n]{a} = a^{\frac{1}{n}}$ . We have, also, then  $\sqrt[n]{(a+b)} = (a+b)^{\frac{1}{n}}$ ;  $\sqrt[n]{(a+b)} = (a+b)^{\frac{1}{n}}$ ; and  $\sqrt[n]{(a+b)} = (a+b)^{\frac{1}{n}}$ , &c. Whence, if the square root of  $a+b$  is required, we have only in the general formula to substitute the fraction  $\frac{1}{2}$  for the exponent  $n$ , and we shall have, first, for the coefficients—

$\frac{n}{1} = \frac{1}{2}$ ;  $\frac{n-1}{2} = -\frac{1}{4}$ ;  $\frac{n-2}{3} = -\frac{3}{8}$ ;  $\frac{n-3}{4} = -\frac{5}{16}$ ;  $\frac{n-4}{5} = -\frac{7}{32}$ ;  $\frac{n-5}{6} = -\frac{9}{64}$ . Then,  $a^n = a^{\frac{1}{2}} = \sqrt{a}$ , and  $a^{n-1} = \frac{1}{\sqrt{a}}$ ;  $a^{n-2} = \frac{1}{a\sqrt{a}}$ ;  $a^{n-3} = \frac{1}{aa\sqrt{a}}$ , &c. : or the powers of  $a$  may be expressed as follows:  $a^{n-1} = \frac{\sqrt{a}}{a}$ ;  $a^n = \frac{a^{\frac{1}{2}}}{a^{\frac{1}{2}}} = \frac{\sqrt{a}}{a^{\frac{1}{2}}}$ ;  $a^{n-3} = \frac{a^{\frac{1}{2}}}{a^{\frac{3}{2}}} = \frac{\sqrt{a}}{a^{\frac{3}{2}}}$ ;  $a^{n-4} = \frac{a^{\frac{1}{2}}}{a^{\frac{4}{2}}} = \frac{\sqrt{a}}{a^2}$ , &c.

The square root, then, of  $a+b$  may be expressed in the following manner,

$$\sqrt{a+b} = \sqrt{a} + \frac{1}{2} b \frac{\sqrt{a}}{a} - \frac{1}{2} \times \frac{1}{4} b^2 \frac{\sqrt{a}}{aa} + \frac{1}{2} \times \frac{1}{4} \times \frac{3}{8} b^3 \frac{\sqrt{a}}{a^3} - \frac{1}{2} \times \frac{1}{4} \times \frac{3}{8} \times \frac{5}{16} b^4 \frac{\sqrt{a}}{a^4}, \&c.$$

715. Hence, if  $a$  be a square number, the value of  $\sqrt{a}$  may be assigned, and the square root of  $a+b$  may also be expressed by an infinite series without any radical sign. Suppose, for instance,  $a=cc$ , we shall have  $\sqrt{a}=c$ ; then  $\sqrt{(cc+b)} = c + \frac{1}{2} \times \frac{b}{c} - \frac{1}{8} \frac{bb}{c^3} + \frac{1}{16} \times \frac{b^3}{c^5} - \frac{1}{128} \times \frac{b^4}{c^7}$ , &c. So that there is no number whose square root may not be extracted in the same way; for every number may be resolved into two parts, one whereof is a square, represented by  $cc$ . Thus, if we require the square root of 6, make  $6=4+2$ , then  $cc=4$ ,  $c=2$ ,  $b=2$ , whence results  $\sqrt{6} = 2 + \frac{1}{2} - \frac{1}{16} + \frac{1}{64} - \frac{5}{128}$ , &c.; and, taking only the two leading terms of this series, we find  $2\frac{1}{2} = \frac{5}{2}$ , whose square  $\frac{25}{4}$  is  $\frac{1}{4}$  greater than 6; but if we take three terms, we shall have  $2\frac{7}{8} = \frac{27}{8}$ , whose square  $\frac{729}{64}$  is still  $\frac{9}{64}$  too small. As  $\frac{5}{2}$  in this example approaches very nearly to the true value of  $\sqrt{6}$ , we will take for 6 its equivalent quantity  $\frac{25}{4} - \frac{1}{4}$ . Thus

$cc = \frac{25}{4}$ ;  $c = \frac{5}{2}$ ;  $b = \frac{1}{2}$ ; and using the two leading terms, we find  $\sqrt{6} = \frac{5}{2} + \frac{1}{4} \times \frac{-1}{\frac{5}{2}} = \frac{5}{2} - \frac{1}{4} \times \frac{2}{5} = \frac{5}{2} - \frac{1}{10} = \frac{24}{10} = \frac{12}{5}$ , and the square of this fraction being  $\frac{144}{25}$ , exceeds the  $\sqrt{6}$  only by  $\frac{1}{100}$ .

716. Now, taking  $6 = \frac{3601}{100} - \frac{1}{100}$ , so that  $c = \frac{60}{10}$  and  $b = \frac{1}{100}$ , and still confining ourselves to the two leading terms, we have  $\sqrt{6} = \frac{60}{10} + \frac{1}{2} \times \frac{-1}{\frac{60}{10}} = \frac{60}{10} - \frac{1}{2} \times \frac{10}{60} = \frac{60}{10} - \frac{1}{12} = \frac{719}{120}$ , the square whereof is  $\frac{51681}{14400}$ . Now 6, when reduced to the same denominator, is  $\frac{8640}{14400}$ ; the error, therefore, is only  $\frac{1}{384000}$ .

717. In a similar way may be expressed the cube root of  $a+b$  by an infinite series. For, as

$\sqrt[n]{a+b} = (a+b)^{\frac{1}{n}}$ , we shall have in the general formula  $n = \frac{1}{2}$ , and the coefficients will be  $\frac{n-1}{1} = -\frac{1}{2}$ ;  $\frac{n-2}{2} = -\frac{1}{2}$ ;  $\frac{n-3}{3} = -\frac{1}{2}$ ;  $\frac{n-4}{4} = -\frac{1}{2}$ ;  $\frac{n-5}{5} = -\frac{1}{2}$ , &c., and for the powers of  $a$  we have  $a^n = \sqrt[n]{a}$ ;  $a^{n-1} = \frac{\sqrt[n]{a}}{a}$ ;  $a^{n-2} = \frac{\sqrt[n]{a}}{a^2}$ ;  $a^{n-3} = \frac{\sqrt[n]{a}}{a^3}$ , &c. Then  $\sqrt[n]{a+b} = \sqrt[n]{a} + \frac{1}{2} \times b \frac{\sqrt[n]{a}}{a} + \frac{1}{2} \times b^2 \frac{\sqrt[n]{a}}{a^2} + \frac{1}{6} \times b^3 \frac{\sqrt[n]{a}}{a^3} - \frac{10}{243} \times b^4 \frac{\sqrt[n]{a}}{a^4}$ , &c. But if  $a$  be a cube or  $a = c^3$ , we have  $\sqrt[n]{a} = c$  and the radical signs will vanish, for we shall have  $\sqrt[n]{c^3+b} = c + \frac{1}{2} \times \frac{b}{c^2} - \frac{1}{2} \times \frac{b^2}{c^5} + \frac{5}{81} \times \frac{b^3}{c^8} - \frac{10}{243} \times \frac{b^4}{c^{11}} + \&c.$

718. Thus we arrive at a formula, enabling us by approximation, as it is called, to find the cube root of any number, because every number may be resolved into two parts, as  $c^3 + b$ , whereof the first is a cube. If, for example, we are required to determine the cube root of 2, we represent 2 by  $1 + 1$ , so that  $c = 1$  and  $b = 1$ , consequently  $\sqrt[3]{2} = 1 + \frac{1}{2} - \frac{1}{8} + \frac{5}{243}$ , &c. The two leading terms of which series make  $1\frac{1}{2} = \frac{3}{2}$ , the cube of which,  $\frac{27}{8}$ , is too great by  $\frac{19}{8}$ . Let us then make  $2 = \frac{64}{32} - \frac{10}{32}$ ; we shall now have  $c = \frac{4}{3}$ , and  $b = -\frac{10}{27}$ , and therefore  $\sqrt[3]{2} = \frac{4}{3} + \frac{1}{3} \times \frac{-10}{27} = \frac{4}{3} - \frac{10}{81} = \frac{112}{81}$ , the cube whereof is  $\frac{13728}{531441}$ . But  $2 = \frac{746496}{373248}$ ; so that the error is  $\frac{7075}{373248}$ . Thus we may approximate the root; and the faster, as a greater number of terms is taken.

RESOLUTION OF NEGATIVE POWERS.

719. It has already been seen that  $\frac{1}{a}$  may be expressed by  $a^{-1}$ . For the same reason,  $\frac{1}{a+b}$  may be represented by  $(a+b)^{-1}$ ; hence the fraction  $\frac{1}{a+b}$  may be considered as a power of  $a+b$ , namely, that whose exponent is  $-1$ ; hence we conclude that the series already found as the value of  $(a+b)^n$  will extend to this case.

720. As  $\frac{1}{a+b}$  is the same as  $(a+b)^{-1}$ , let us assume, in the general formula,  $n = -1$ ; then for coefficients we shall first have  $\frac{n-1}{1} = -1$ ;  $\frac{n-2}{2} = -1$ ;  $\frac{n-3}{3} = -1$ ;  $\frac{n-4}{4} = -1$ , &c. For the powers of  $a$  we shall then have  $a^n = a^{-1} = \frac{1}{a}$ ;  $a^{n-1} = a^{-2} = \frac{1}{a^2}$ ;  $a^{n-2} = \frac{1}{a^3}$ ;  $a^{n-3} = \frac{1}{a^4}$ , &c. So that  $(a+b)^{-1} = \frac{1}{a+b} = \frac{1}{a} - \frac{b}{a^2} + \frac{b^2}{a^3} - \frac{b^3}{a^4} + \frac{b^4}{a^5} - \frac{b^5}{a^6}$ , &c., which is the same series before found by division.

721. Now,  $\frac{1}{(a+b)^2}$  being the same as  $(a+b)^{-2}$ , let us reduce it to an infinite series; for which purpose we must suppose  $n = -2$ , and we have for the coefficients  $\frac{n-1}{1} = -2$ ;  $\frac{n-2}{2} = -\frac{3}{2}$ ;  $\frac{n-3}{3} = -\frac{4}{3}$ ;  $\frac{n-4}{4} = -\frac{5}{4}$ , &c. And for the powers of  $a$   $a^n = \frac{1}{a^2}$ ;  $a^{n-1} = \frac{1}{a^3}$ ;  $a^{n-2} = \frac{1}{a^4}$ ;  $a^{n-3} = \frac{1}{a^5}$ , &c. We therefore obtain  $(a+b)^{-2} = \frac{1}{(a+b)^2} = \frac{1}{a^2} - \frac{2}{a^3} + \frac{3}{a^4} - \frac{4}{a^5} + \frac{5}{a^6} - \frac{6}{a^7} + \frac{7}{a^8} - \frac{8}{a^9} + \frac{9}{a^{10}} - \frac{10}{a^{11}} + \frac{11}{a^{12}} - \frac{12}{a^{13}} + \frac{13}{a^{14}} - \frac{14}{a^{15}} + \frac{15}{a^{16}} - \frac{16}{a^{17}} + \frac{17}{a^{18}} - \frac{18}{a^{19}} + \frac{19}{a^{20}} - \frac{20}{a^{21}} + \frac{21}{a^{22}} - \frac{22}{a^{23}} + \frac{23}{a^{24}} - \frac{24}{a^{25}} + \frac{25}{a^{26}} - \frac{26}{a^{27}} + \frac{27}{a^{28}} - \frac{28}{a^{29}} + \frac{29}{a^{30}} - \frac{30}{a^{31}} + \frac{31}{a^{32}} - \frac{32}{a^{33}} + \frac{33}{a^{34}} - \frac{34}{a^{35}} + \frac{35}{a^{36}} - \frac{36}{a^{37}} + \frac{37}{a^{38}} - \frac{38}{a^{39}} + \frac{39}{a^{40}} - \frac{40}{a^{41}} + \frac{41}{a^{42}} - \frac{42}{a^{43}} + \frac{43}{a^{44}} - \frac{44}{a^{45}} + \frac{45}{a^{46}} - \frac{46}{a^{47}} + \frac{47}{a^{48}} - \frac{48}{a^{49}} + \frac{49}{a^{50}} - \frac{50}{a^{51}} + \frac{51}{a^{52}} - \frac{52}{a^{53}} + \frac{53}{a^{54}} - \frac{54}{a^{55}} + \frac{55}{a^{56}} - \frac{56}{a^{57}} + \frac{57}{a^{58}} - \frac{58}{a^{59}} + \frac{59}{a^{60}} - \frac{60}{a^{61}} + \frac{61}{a^{62}} - \frac{62}{a^{63}} + \frac{63}{a^{64}} - \frac{64}{a^{65}} + \frac{65}{a^{66}} - \frac{66}{a^{67}} + \frac{67}{a^{68}} - \frac{68}{a^{69}} + \frac{69}{a^{70}} - \frac{70}{a^{71}} + \frac{71}{a^{72}} - \frac{72}{a^{73}} + \frac{73}{a^{74}} - \frac{74}{a^{75}} + \frac{75}{a^{76}} - \frac{76}{a^{77}} + \frac{77}{a^{78}} - \frac{78}{a^{79}} + \frac{79}{a^{80}} - \frac{80}{a^{81}} + \frac{81}{a^{82}} - \frac{82}{a^{83}} + \frac{83}{a^{84}} - \frac{84}{a^{85}} + \frac{85}{a^{86}} - \frac{86}{a^{87}} + \frac{87}{a^{88}} - \frac{88}{a^{89}} + \frac{89}{a^{90}} - \frac{90}{a^{91}} + \frac{91}{a^{92}} - \frac{92}{a^{93}} + \frac{93}{a^{94}} - \frac{94}{a^{95}} + \frac{95}{a^{96}} - \frac{96}{a^{97}} + \frac{97}{a^{98}} - \frac{98}{a^{99}} + \frac{99}{a^{100}} - \frac{100}{a^{101}} + \frac{101}{a^{102}} - \frac{102}{a^{103}} + \frac{103}{a^{104}} - \frac{104}{a^{105}} + \frac{105}{a^{106}} - \frac{106}{a^{107}} + \frac{107}{a^{108}} - \frac{108}{a^{109}} + \frac{109}{a^{110}} - \frac{110}{a^{111}} + \frac{111}{a^{112}} - \frac{112}{a^{113}} + \frac{113}{a^{114}} - \frac{114}{a^{115}} + \frac{115}{a^{116}} - \frac{116}{a^{117}} + \frac{117}{a^{118}} - \frac{118}{a^{119}} + \frac{119}{a^{120}} - \frac{120}{a^{121}} + \frac{121}{a^{122}} - \frac{122}{a^{123}} + \frac{123}{a^{124}} - \frac{124}{a^{125}} + \frac{125}{a^{126}} - \frac{126}{a^{127}} + \frac{127}{a^{128}} - \frac{128}{a^{129}} + \frac{129}{a^{130}} - \frac{130}{a^{131}} + \frac{131}{a^{132}} - \frac{132}{a^{133}} + \frac{133}{a^{134}} - \frac{134}{a^{135}} + \frac{135}{a^{136}} - \frac{136}{a^{137}} + \frac{137}{a^{138}} - \frac{138}{a^{139}} + \frac{139}{a^{140}} - \frac{140}{a^{141}} + \frac{141}{a^{142}} - \frac{142}{a^{143}} + \frac{143}{a^{144}} - \frac{144}{a^{145}} + \frac{145}{a^{146}} - \frac{146}{a^{147}} + \frac{147}{a^{148}} - \frac{148}{a^{149}} + \frac{149}{a^{150}} - \frac{150}{a^{151}} + \frac{151}{a^{152}} - \frac{152}{a^{153}} + \frac{153}{a^{154}} - \frac{154}{a^{155}} + \frac{155}{a^{156}} - \frac{156}{a^{157}} + \frac{157}{a^{158}} - \frac{158}{a^{159}} + \frac{159}{a^{160}} - \frac{160}{a^{161}} + \frac{161}{a^{162}} - \frac{162}{a^{163}} + \frac{163}{a^{164}} - \frac{164}{a^{165}} + \frac{165}{a^{166}} - \frac{166}{a^{167}} + \frac{167}{a^{168}} - \frac{168}{a^{169}} + \frac{169}{a^{170}} - \frac{170}{a^{171}} + \frac{171}{a^{172}} - \frac{172}{a^{173}} + \frac{173}{a^{174}} - \frac{174}{a^{175}} + \frac{175}{a^{176}} - \frac{176}{a^{177}} + \frac{177}{a^{178}} - \frac{178}{a^{179}} + \frac{179}{a^{180}} - \frac{180}{a^{181}} + \frac{181}{a^{182}} - \frac{182}{a^{183}} + \frac{183}{a^{184}} - \frac{184}{a^{185}} + \frac{185}{a^{186}} - \frac{186}{a^{187}} + \frac{187}{a^{188}} - \frac{188}{a^{189}} + \frac{189}{a^{190}} - \frac{190}{a^{191}} + \frac{191}{a^{192}} - \frac{192}{a^{193}} + \frac{193}{a^{194}} - \frac{194}{a^{195}} + \frac{195}{a^{196}} - \frac{196}{a^{197}} + \frac{197}{a^{198}} - \frac{198}{a^{199}} + \frac{199}{a^{200}} - \frac{740}{a^{741}} + \frac{741}{a^{742}} - \frac{742}{a^{743}} + \frac{743}{a^{744}} - \frac{744}{a^{745}} + \frac{745}{a^{746}} - \frac{746}{a^{747}} + \frac{747}{a^{748}} - \frac{748}{a^{749}} + \frac{749}{a^{750}} - \frac{750}{a^{751}} + \frac{751}{a^{752}} - \frac{752}{a^{753}} + \frac{753}{a^{754}} - \frac{7$

$$\frac{1}{a} - \frac{b}{a^2} + \frac{b^2}{a^3} - \frac{b^3}{a^4} + \frac{b^4}{a^5} - \frac{b^5}{a^6} + \&c.$$

$$1 - \frac{b}{a} + \frac{b^2}{a^2} - \frac{b^3}{a^3} + \frac{b^4}{a^4} - \frac{b^5}{a^5} + \&c.$$

$$+ \frac{b}{a} - \frac{b^2}{a^2} + \frac{b^3}{a^3} - \frac{b^4}{a^4} + \frac{b^5}{a^5} - \&c.$$

1

725. It has also been shown that  $\frac{1}{(a+b)^2} = \frac{1}{aa} - \frac{2b}{a^3} + \frac{3bb}{a^4} - \frac{4b^3}{a^5} + \frac{5b^4}{a^6} - \frac{6b^5}{a^7} + \&c.$  If, as before, this series be multiplied by  $(a+b)^2$  or  $aa + 2ab + bb$ , the product will be found to be  $=1$ .

726. If the series found for the value of  $\frac{1}{(a+b)^2}$  be multiplied by  $a+b$  only, the product ought to be the fraction  $\frac{1}{a+b}$ , or be equal to the series already found, namely,  $\frac{1}{a} - \frac{b}{a^2} + \frac{bb}{a^3} - \frac{b^3}{a^4} + \frac{b^4}{a^5} + \&c.$ ; and that, on multiplication, will be found to be the case.

## ARITHMETICAL RATIO.

727. The relation which one quantity bears to another, with respect to magnitude, is called a *ratio*. It is evident that no relation can exist between quantities that are not of a similar kind; as, for example, a number must be compared with a number, a line with a line, &c. The magnitudes of quantities may be compared in two ways. In the first, they may be compared with regard to their *difference*; and then the question asked is, how much one quantity is greater or less than another? The relation in this respect, which quantities bear to each other, is called their *arithmetical ratio*. The other way in which they may be compared is, by inquiring how often one quantity is greater than another? and this relation between quantities is called their *geometrical ratio*. The term ratio, when simply applied, is generally understood in the latter sense; and we shall reserve the word *ratio* and *relation* to express geometrical ratios.

728. By subtraction, the difference is found between two numbers; hence the question, how much the one is greater than the other, is easily resolved. Thus, between two equal numbers, the difference being nothing, if we are asked how much one of the numbers is greater than the other, the answer is, by nothing. Thus, 8 being  $= 2 \times 4$ , the difference between 8 and  $2 \times 4$  is 0.

729. When two numbers, as 5 and 3, are not equal, and we require to know how much 5 is greater than 3, the answer is 2, and it is obtained by subtracting 3 from 5. So 17 is greater than 7 by 10, and 25 exceeds 8 by 17. There are therefore three things relative to the subject for our consideration: 1st, the greater of the two numbers; 2d, the less; and 3d, the difference; which three quantities are so connected, that two of the three being given, the third may also be determined. Suppose the greater number  $= a$ , the less  $= b$ , and the difference  $= d$ , the difference will be found by subtracting  $b$  from  $a$ , so that  $d = a - b$ , whence we find  $d$ , if  $a$  and  $b$  are given.

730. But if the difference and the less  $b$  of the two numbers are given, the greater number is determined by adding the difference to the less number, which gives  $a = b + d$ ; for if we take from  $b + d$  the less number  $b$ , there remains  $d$ , which is the known difference. Let the number  $= 12$  and the difference  $= 8$ , then the greater number  $= 20$ . Lastly, if  $a$  the greater be given, and  $d$  the difference,  $b$  will be found by subtracting the difference from the greater number, that is,  $b = a - d$ .

731. The connection, then, among the numbers is of such a nature as to give these results:—1st.  $d = a - b$ ; 2d.  $a = b + d$ ; 3d.  $b = a - d$ ; and, generally, if  $z = x + y$ , then  $y = z - x$  and  $x = z - y$ . It must here be remarked, with respect to arithmetical ratios, that if any number, as  $c$ , be added to the numbers  $a$  and  $b$ , the difference is still the same. Thus,  $d$  being the difference between  $a$  and  $b$ , that number  $d$  will also be the difference between  $a + c$  and  $b + c$ , and between  $a - c$  and  $b - c$ . Thus, the difference between 20 and 8 being 12, such difference will remain the same whatever numbers we add to 20 and 12, and whatever numbers we subtract from them; for if  $a - b = d$ , we must have  $(a + c) - (b + c) = d$ , as also  $(a - c) - (b - c) = d$ . So, if the numbers be doubled, the difference will be double, and, generally,  $na - nb = nd$ , whatever be the value of  $a$ .

## ARITHMETICAL PROPORTION.

732. When two arithmetical ratios or relations are equal, the equality is called an *arithmetical proportion*. Thus, if  $a - b = p - q$ , the difference between  $p$  and  $q$  being the same as that between  $a$  and  $b$ , these four numbers are said to form an arithmetical proportion, which is thus written,  $a - b = p - q$ . An arithmetical proportion, then, consists of four terms, which are such that, subtracting the second term from the first, the remainder is the same as when we subtract the fourth from the third; thus the numbers 24, 9, 23, 8, form an

arithmetical proportion, because  $24 - 9 = 23 - 8$ , which by some is written  $24 : 9 :: 23 : 8$ . In any arithmetical proportion, as  $a - b = p - q$ , the second and third quantities may change places without changing the equality; for as  $a - b = p - q$ , add  $b$  to both sides, and we have  $a = b + p - q$ ; and now subtracting  $p$  from both sides, we have  $a - b = p - q$ . In numbers, as  $24 - 9 = 23 - 8$ , so  $24 - 23 = 9 - 8$ . In an arithmetical proportion, the second term may take the place of the first, if the fourth be made to take the place of the third; thus, if  $a - b = p - q$ , we have  $b - a = q - p$ . For  $b - a$  is the negative of  $a - b$ , and  $q - p$  is the negative of  $p - q$ . But the great property of every arithmetical proportion is this, that the sum of the second and third terms is always equal to the sum of the first and fourth; a property which deserves particular consideration, and is expressed by saying that the sum of the *means* (middle terms) is equal to the sum of the *extremes* (extreme terms). Thus, since  $24 - 9 = 23 - 8$ , we have  $9 + 23 = 24 + 8$ , both being 32. The demonstration of this is as follows: Let  $a - b = p - q$ , add to both  $b + q$ , and we have  $a + q = b + p$ , that is, the sum of the first and fourth is equal to the sum of the second and third; and inversely, if four numbers,  $a, b, p, q$ , be such that the sum of the second and third is equal to that of the first and fourth, that is, if  $b + p = a + q$ , we may be sure that those numbers are in arithmetical proportion, and that  $a - b = p - q$ ; for if  $a + q = b + p$ , subtracting from both sides  $b + q$ , we obtain  $a - b = p - q$ . Thus the numbers 24, 12, 27, 15, being such that the sum of the means ( $12 + 27 = 39$ ) is equal to the sum of the extremes ( $24 + 15 = 39$ ), we are certain that they form an arithmetical proportion, and consequently that  $24 - 12 = 27 - 15$ .

733. By this property, the following question is resolved: — The three first terms of an arithmetical proportion being given, to find the fourth, let  $a, b, p$  be the three first terms, and let the fourth, which is that sought, be represented by  $q$ . Then  $a + q = b + p$ ; by subtracting  $a$  from both sides we have  $q = b + p - a$ . Hence it appears that the fourth term is found by adding together the second and third, and from their sum subtracting the first. Thus, suppose the three first terms are 24, 12, 27, the sum of the second and third is  $= 39$ , from which subtract 24, the first, and we have 15 for the fourth term sought. When in an arithmetical proportion the second term is equal to the third, we have only three numbers, whose property is this, that the first minus the second is equal to the second minus the third, or that the differences between the first and second and between the second and third are equal. Of this kind are the numbers 23, 18, 13, since  $23 - 18 = 18 - 13$ . Three such numbers, as 23, 18, 13, are said to form a continued arithmetical proportion, called an *arithmetical progression*, particularly when a great number of such terms follow each other according to the same law. An arithmetical progression may be either *increasing* or *decreasing*; that is to say, the former when the terms go on increasing, as 5, 9, 13, and the latter when they go on diminishing, as 12, 9, 6.

734. Let us suppose the numbers  $a, b, c$  to be in arithmetical progression; then  $a - b = b - c$ ; hence from the equality between the sum of the extremes and that of the means,  $2b = a + c$ , if we subtract  $a$  from both, we have  $c = 2b - a$ : hence, when the two first terms  $a, b$  of an arithmetical progression are given, the third is found by taking the first from twice the second. Thus let 2 and 5 be the two first terms of an arithmetical progression, the third will be  $2 \times 5 - 2 = 8$ ; and the three numbers 2, 5, 8 give the proportion  $2 - 5 = 5 - 8$ . This method enables us to obtain, to any extent, an arithmetical progression; for we have only to find the fourth by means of the second and third in the same way as the third was determined by means of the first and second, and so on. Let  $a$  be the first term and  $b$  the second, the third will be  $= 2b - a$ , the fourth  $4b - 2a - b = 3b - 2a$ , the fifth will be  $6b - 4a - 2b + a = 4b - 3a$ , the sixth  $= 8b - 6a - 3b + 2a = 5b - 4a$ , &c.

## ARITHMETICAL PROGRESSION.

735. Having in the preceding subsection seen the nature of arithmetical progression, we may perceive that the natural numbers written in their order (as 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, &c.) form an increasing arithmetical progression, because they increase constantly by unity; and the series 23, 21, 19, 17, 15, 13, 11, 9, 7, 5, 3, 1 is also such a progression wherein the numbers constantly decrease by 2. The number or quantity by which an arithmetical progression increases or decreases is called the *difference*. Hence, if the first term and difference be given, we may continue it to any extent. For instance, let the first term  $= 3$ , and the difference  $= 4$ , we shall have the following increasing progression, 3, 7, 11, 15, 19, 23, 27, 31, 35, &c., wherein each succeeding term is found by adding the difference to the preceding one. It is usual to write the natural numbers 1, 2, 3, 4, &c. above the term of such an arithmetical progression, in order that we may perceive the rank held by any term in the progression. The numbers so written above the terms are called the *indices*, as in the following example: —

Indices	-   -   -   -   1   2   3   4   5   6   7   8   9   10   11
Arithmetical progression	3, 7, 11, 15, 19, 23, 27, 31, 35, 39, 43, &c.;

in which we see 43 is the eleventh term.

736. Let  $a$  be the first term, and  $d$  the difference, the following will be the order of it:—

$$\begin{array}{ccccccc} 1 & 2 & 3 & 4 & 5 & 6 & 7 \\ a, & a+d, & a+2d, & a+3d, & a+4d, & a+5d, & a+6d, \&c. \end{array}$$

Whence it is evident, that any term of the progression may be found without the necessity of finding the intermediate ones merely by the first term, and the difference  $d$ ; for example, the twelfth term,  $=a+11d$ , the thousandth term,  $=a+999d$ , and generally the last term  $=a+(n-1)d$ ; hence it is only necessary to multiply the difference by the number of terms minus one, and to the product to add the first term. Thus, suppose an arithmetical progression of a hundred terms whose first term is  $=6$ , and the difference  $=5$ , then the last term will be  $=99 \times 5 + 6 = 501$ .

737. Knowing the first term  $a$ , and the last  $z$ , the number of terms  $n$ , we can find the difference  $d$ . For since the last term  $z=a+(n-1)d$ , if we subtract  $a$  from both sides, we obtain  $z-a=(n-1)d$ . Then, by subtracting the first term from the last, we have the product of the difference multiplied by the number of terms minus 1. And dividing  $z-a$  by  $n-1$ , the required value of the difference will be  $=\frac{z-a}{n-1}$ ; from which results the following rule: subtract the first term from the last, divide the remainder by the number of terms minus 1, and the quotient will be the difference, by which the whole progression may be written—

Example.—Let the first term  $=2$ , the last 26, to find the difference,  
 $\frac{26-2}{9-1}=\frac{24}{8}=3$  the quotient  $=3$  will be equal to the difference, and the progression will be as under:—

$$\begin{array}{ccccccc} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 \\ 2, & 5, & 8, & 11, & 14, & 17, & 20, & 23, & 26. \end{array}$$

738. Another example.—Let the first term  $=2\frac{1}{2}$ , the last  $=12\frac{1}{2}$ , the number of terms  $=7$ ; then the difference will be

$$\frac{12\frac{1}{2}-2\frac{1}{2}}{7-1}=\frac{10\frac{1}{2}}{6}=\frac{61}{36}=1\frac{25}{36}, \text{ and the progression will be}$$

$$\begin{array}{ccccccc} 1 & 2 & 3 & 4 & 5 & 6 & 7 \\ 2\frac{1}{2}, & 4\frac{1}{3}, & 5\frac{1}{3}, & 7\frac{5}{12}, & 9\frac{1}{2}, & 10\frac{23}{36}, & 12\frac{1}{2}. \end{array}$$

739. If the first term  $a$ , the last term  $z$ , and the difference  $d$  be given, we may from these find the number of terms  $n$ . For, inasmuch as  $z-a=(n-1)d$ , if we divide the two sides by  $d$ , we have  $\frac{z-a}{d}=n-1$ , and  $n$  being greater by 1 than  $n-1$ , we have  $n=\frac{z-a}{d}+1$ ; the number of terms is therefore found by dividing the difference between the first and last terms, or  $z-a$  by the difference of the progression, and adding unity to the quotient  $\frac{z-a}{d}$ .

740. Thus, for example, let the first term  $=4$ , the last  $=100$ , and the difference  $=12$ ; the number of terms will be  $\frac{100-4}{12}+1=9$ , and these nine terms will be

$$\begin{array}{ccccccc} 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 \\ 4, & 16, & 28, & 40, & 52, & 64, & 76, & 88, & 100. \end{array}$$

Another example.—Let the first term  $=3\frac{1}{3}$ , the last  $=7\frac{2}{3}$ , and the difference  $=1\frac{1}{3}$ ; the number of terms will be  $\frac{7\frac{2}{3}-3\frac{1}{3}}{1\frac{1}{3}}+1=4$ , which are  $3\frac{1}{3}, 4\frac{2}{3}, 6\frac{1}{3}, 7\frac{2}{3}$ .

741. It must, however, be remarked, that the number of terms being necessarily an integer, if such a number had not been obtained for  $n$  in the foregoing examples, the questions would have been absurd; and if an integer number be not obtained for the value  $\frac{z-a}{d}$ , the question cannot be resolved; hence, in order that such questions may be possible,  $z-a$  must be divisible by  $d$ .

742. It may now be concluded, then, that there are always four quantities for consideration in an arithmetical progression. 1. The first term,  $a$ . 2. The last term,  $z$ . 3. The difference,  $d$ . 4. The number of terms,  $n$ ; and the relations of these to each other are such, that, if we know three of them, the fourth may be found. For, 1. If  $a$ ,  $d$ , and  $n$  are known, we have  $z=a+(n-1)d$ . 2. If  $z$ ,  $d$ , and  $n$  are known, we have  $a=z-(n-1)d$ . 3. If  $a$ ,  $z$ , and  $n$  are known, we have  $d=\frac{z-a}{n-1}$ . 4. If  $a$ ,  $z$ , and  $d$  are known, we have  $n=\frac{z-a}{d}+1$ .

#### SUMMATION OF ARITHMETICAL PROGRESSIONS.

743. To find the form of an arithmetical progression by adding all the terms together would be troublesome when the number of terms is very great; a rule has therefore been found by which the operation is much shortened. Let us first consider a particular given

progression, whose first term = 2, difference = 3, the last term = 29, and the number of terms = 10.

1 2 3 4 5 6 7 8 9 10  
2, 5, 8, 11, 14, 17, 20, 23, 26, 29.

744. In this progression, the sum of the first and last term = 31, the sum of the second and last but one = 31, and so on; from which we conclude that the sum of any two terms equally distant, the one from the first, the other from the last term, is always equal to that of the first and last. It will not be difficult to discover the cause of this; for, suppose the first =  $a$ , the last =  $z$ , and the difference =  $d$ , the sum of the first and last is =  $a + z$ , and the second term being =  $a + d$ , and the last but one =  $z - d$ ; the sum of these two terms is also =  $a + z$ . Again, the third term being  $a + 2d$ , and the last term but two =  $z - 2d$ , it is evident that the sum of these two terms also makes  $a + z$ . From this, the demonstration for the rest is obvious. Now, if we write the progression term by term twice over, but in one line, invert the order of the terms, and add the corresponding terms together, we shall have as follows:—

$$\begin{array}{r} 2 + 5 + 8 + 11 + 14 + 17 + 20 + 23 + 26 + 29 \\ 29 + 26 + 23 + 20 + 17 + 14 + 11 + 8 + 5 + 2 \\ \hline 31 + 31 + 31 + 31 + 31 + 31 + 31 + 31 + 31 + 31 \end{array}$$

A series of equal terms, evidently equal to twice the sum of the given progression, whose number of terms being 10, the sum here exhibited will be =  $10 \times 31 = 310$ . Hence, as this is twice the sum of the arithmetical progression, the sum required must be 155.

745. Treating in the same manner any arithmetical progression whose first term =  $a$ , last term =  $z$ , and number of terms =  $n$ , and writing as above shown, the progression direct and inverted, the one under the other, and adding term to term, we have a series of  $n$  terms each =  $a + z$ , whose sum will consequently be =  $n(a + z)$ , which will be twice the sum of the proposed arithmetical progression, and therefore =  $\frac{n(a+z)}{2}$ . From which flows a simple rule for finding the sum of an arithmetical progression. Multiply the sum of the first and last terms, and half the product will be the sum of the whole progression. We will illustrate this rule by an example. Let it be required to find the sum of the progression of the natural numbers, 1, 2, 3, &c. to 100. This, by the rule, will be =  $\frac{100 \times 101}{2} = 50 \times 101 = 5050$ .

746. Let it be required to find the sum of an arithmetical progression whose first term is = 5, the difference = 3, and the number of terms = 32: we must begin by using the rules in subsections 735. *et seq.*, by which we determine the last term to be =  $5 + 31 \times 3 = 98$ , after which the sum is immediately seen to be =  $\frac{103 \times 32}{2} = 103 \times 16 = 1648$ . Generally, to find the sum of the whole progression, let the first term be =  $a$ , the difference =  $d$ , and the number of terms =  $n$ . Now, as by the preceding subsection the last term must be =  $a + (n-1)d$ , the sum of the first and last will be  $2a + (n-1)d$ ; multiplying this sum by the number of terms  $n$ , we have  $2na + n(n-1)d$ ; the sum required, therefore, will be =  $na + \frac{n(n-1)d}{2}$ , and this formula, applied to the preceding example, gives 1648, as before.

747. Suppose it required to add together all the natural numbers from 1 to  $n$ , we have for resolving the question the first term = 1, the last term =  $n$ , and the number of terms =  $n$ , the sum required is =  $\frac{nn+n}{2} = \frac{n(n+1)}{2}$ . Let  $n$  be = 1766, then the sum of all the numbers from 1 to 1766 =  $883 \times 1767 = 1560261$ .

748. If a progression of uneven numbers be proposed, 1, 3, 5, 7, &c. continued to  $n$  terms, and the sum be required. We have the first term = 1, the difference = 2, the number of terms =  $n$ ; the last term will therefore be =  $1 + (n-1)2 = 2n-1$ , and, consequently, the sum =  $nn$ . Hence, whatever number of terms of this progression are added together, the sum will always be a square, namely, the square of the number of terms, as a view of the following table will render manifest:—

Indices	-	1	2	3	4	5	6	7	8	9	10, &c.
Progression	-	1	3	5	7	9	11	13	15	17	19, &c.
Sum	-	1	4	9	16	25	36	49	64	81	100, &c.

The subjoined table exhibits formulæ for differences up to 10:—

$$\begin{array}{ll} \text{If } d=1 \text{ the sum will be} & = n + \frac{n(n-1)}{2} = \frac{nn+n}{2} \\ d=2 & \text{---} = n + \frac{2n(n-1)}{2} = nn \\ d=3 & \text{---} = n + \frac{3n(n-1)}{2} = \frac{3nn-n}{2} \\ d=4 & \text{---} = n + \frac{4n(n-1)}{2} = 2nn-n \end{array}$$

$$\begin{aligned}
 \text{If } d=5 \text{ the sum will be } &= n + \frac{5n(n-1)}{2} = \frac{5nn-3n}{2} \\
 d=6 \quad \quad \quad &= n + \frac{6n(n-1)}{2} = \frac{3nn-2n}{1} \\
 d=7 \quad \quad \quad &= n + \frac{7n(n-1)}{2} = \frac{7nn-5n}{2} \\
 d=8 \quad \quad \quad &= n + \frac{8n(n-1)}{2} = \frac{4nn-3n}{1} \\
 d=9 \quad \quad \quad &= n + \frac{9n(n-1)}{2} = \frac{9nn-7n}{2} \\
 d=10 \quad \quad \quad &= n + \frac{10n(n-1)}{2} = n.
 \end{aligned}$$

## GEOMETRICAL RATIO.

749. We have before observed that the *geometrical ratio* of two numbers is found by answering the question *how many times* is one of those numbers greater than the other, the quotient being the ratio required. Three things here present themselves for consideration. Firstly, the first of the two given numbers, which is called the *antecedent*; secondly, the other number, which is called the *consequent*; thirdly, the *ratio* of the two numbers, or quotient arising from the division of the antecedent by the consequent. Thus, if the relation of the numbers 18 and 12 be sought, 18 being the antecedent, and 12 the consequent, the ratio will be  $\frac{18}{12}=1\frac{1}{2}$ , whence we see the antecedent contains the consequent once and a half. Geometrical relations are generally represented by a point placed above another between the antecedent and the consequent. Thus  $a : b$  signifies the geometrical relation of these two numbers, or the ratio of  $b$  to  $a$ . The sign just mentioned has, in a previous page, been given as indicating division, and it is on that account here used, because, in order to know the ratio, we divide  $a$  by  $b$ . The relation is merely read  $a$  is to  $b$ . On this account relation is expressed by a fraction whose numerator is the antecedent and denominator the consequent. It is hardly necessary to say that this fraction should, for perspicuity sake, appear in its lowest terms. Thus  $\frac{18}{12}$ , if both terms be divided by 6, becomes  $\frac{3}{2}$ .

750. Hence relations differ as their ratios are different; and there are, of course, as many kinds of geometrical relations as we can imagine different ratios. The first kind is that wherein the ratio becomes unity, which, of course, happens when the two numbers are equal, as in  $3 : 3$ ,  $4 : 4$ ;  $a : a$ , and because the ratio here is 1, it is called the relation of equality. The relation then follows in which the ratio is another whole number; in  $4 : 2$  the ratio is 2, and is called a *double* ratio; in  $12 : 4$ , the ratio being 3, it is called a *triple* ratio; in  $24 : 6$  the ratio is 4, and is called a *quadruple* ratio. It is necessary, also, to notice those relations whose ratios are expressed by fractions, as  $12 : 9$ , where the ratio is  $\frac{4}{3}$ , or  $1\frac{1}{3}$ ;  $18 : 27$ , where the ratio is  $\frac{2}{3}$ , &c. Those relations, as  $6 : 12$ ,  $5 : 15$ , &c., wherein the consequent contains exactly twice, thrice, &c. the antecedent, are sometimes called *subduplex*, *subtriple*, &c. ratios. The term *rational* is applied to ratios that are expressible numbers, the antecedent and consequent being integers, as  $11 : 7$ ,  $8 : 15$ , &c.; and that of *irrational*, or *surd*, is applied to ratios neither expressible by integers nor by fractions, as  $\sqrt{5} : 8$ ,  $4 : \sqrt{3}$ .

751. If  $a$  be the antecedent,  $b$  the consequent, and  $d$  the ratio,  $d = \frac{a}{b}$ . Were the consequent  $b$  given with the ratio, we should find  $a = bd$ , for  $bd$  divided by  $b$  gives  $d$ . Finally, when the antecedent  $a$  is given, and the ratio  $d$  the consequent,  $b = \frac{a}{d}$ ; for, dividing the antecedent  $a$  by the consequent (or its equivalent)  $\frac{a}{d}$ , we obtain the quotient  $d$ , that is, the ratio. In whatever way we multiply or divide the consequent and antecedent by the same number, every relation  $a : b$  remains the same, because the ratio is the same. Let  $d$  be the ratio of  $a : b$ , we have then  $d = \frac{a}{b}$ : now the relation  $na : nb$  is still  $\frac{a}{b} = d$ , and likewise  $\frac{a}{n} : \frac{b}{n}$  is still  $\frac{a}{b} = d$ . So, also, when a ratio has been reduced to its lowest terms, the relation is easily perceived and enunciated; for, let the ratio  $\frac{a}{b}$  be reduced to its lowest terms  $\frac{p}{q}$ , we say,  $a : b = p : q$ ,  $a : b :: p : q$ , which is read  $a$  is to  $b$  as  $p$  is to  $q$ . Thus the ratio of the relation  $6 : 3$  being  $\frac{2}{1}$ , or 2, we say,  $6 : 3 = 2 : 1$ . So,  $18 : 12 = 3 : 2$ , and  $2418 : 604 = 4 : 1$ , &c. But if the ratio be not susceptible of abridgment, the relation does not become more evident, and we do not simplify a relation by saying  $9 : 7 = 9 : 7$ . We may, however, change the relation of two large numbers into one more simple and evident by reducing both to their lowest terms, for we may say,  $14484 : 7242 = 2 : 1$ , or  $15819 : 10546 = 3 : 2$ , or  $57600 : 25200 = 16 : 7$ . All relations, therefore, should be reduced to the lowest possible numbers, which is readily done by dividing the two terms of the relation by their greatest common divisor. Thus, to reduce the relation  $57600 : 25200$  to that of  $16 : 7$ , we have only to perform the single operation of dividing the numbers 576 and 252 by their greatest common divisor, 36. The method of finding a common divisor of two given numbers will be given in the following subsection.

## GREATEST COMMON DIVISOR.

752. There are many numbers whose only common divisor is unity, and where the numerator and denominator belong to this class, the fraction cannot be reduced to a more convenient form. Such is the case with the numbers 48 and 35; hence, as the division of  $48 : 35$  can only be divided by 1, their relation cannot be more simply expressed. But if two numbers have a common divisor, the greatest they have is found by the following rule. Divide the greater by the lesser number, and divide the preceding divisor by the remainder; the remainder resulting from the last division again becomes the divisor for a third division wherein the preceding divisor is to be the dividend. This operation being repeated till we arrive at a division to which no remainder is left, the last divisor will be found to be the greatest common measure or divisor of the two given numbers. Now, let us apply this to the two numbers 504 and 312, whereof we require the greatest common divisor.

$$\begin{array}{r}
 312)504(1 \\
 \underline{312} \\
 192)312(1 \\
 \underline{192} \\
 120)192(1 \\
 \underline{120} \\
 72)120(1 \\
 \underline{72} \\
 48)72(1 \\
 \underline{48} \\
 24)48(2 \\
 \underline{48} \\
 0
 \end{array}$$

Here we perceive that the last divisor is 24, and dividing 504 and 312 by it, we find that the relation  $504 : 312$  is reduced to the form  $21 : 13$ .

Let the relation  $456 : 721$  be given to find the greatest common divisor.

$$\begin{array}{r}
 456)721(1 \\
 \underline{456} \\
 265)456(1 \\
 \underline{265} \\
 191)265(1 \\
 \underline{191} \\
 74)191(2 \\
 \underline{148} \\
 43)74(1 \\
 \underline{43} \\
 31)43(1 \\
 \underline{31} \\
 12)31(2 \\
 \underline{24} \\
 7)12(1 \\
 \underline{7} \\
 5)7(1 \\
 \underline{5} \\
 2)5(2 \\
 \underline{4} \\
 1)2(2 \\
 \underline{2} \\
 0
 \end{array}$$

In this case 1 is the greatest common divisor, and we cannot express the relation  $721 : 456$  by less numbers, nor reduce it to less terms, than those in which it appears.

753. To demonstrate this rule, let  $a$  be the greater and  $b$  the less of the given numbers, and let  $d$  be one of their common divisors; it is evident that  $a$  and  $b$  being divisible by  $d$ , we may also divide the quantities  $a-b$ ,  $a-2b$ ,  $a-3b$ , and, in general,  $a-nb$ , by  $d$ . Equally true must be the converse, that is to say, if the numbers  $b$  and  $a-nb$  are divisible by  $d$ , the number  $a$  will be also divisible by  $d$ . Farther, if  $d$  be the greatest common divisor of two numbers  $b$  and  $a-nb$ , it will also be the greatest common divisor of the two numbers  $a$  and  $b$ : for if a greater common divisor than  $d$  could be found for the numbers  $a$  and  $b$ , it would also be a common divisor of  $b$  and  $a-nb$ , and consequently  $d$  would not be the greatest common divisor of these two numbers. But we have supposed  $d$  the greatest divisor common to  $b$  and  $a-nb$ , wherefore it must also be the greatest common divisor of  $a$  and  $b$ . With these considerations before us, let us, according to the rule, divide the greater number  $a$  by the lesser  $b$ , and let us suppose the quotient  $=n$ ; the remainder will be  $a-nb$ , which must be less than  $b$ . This remainder  $a-nb$  having the same greatest common divisor with  $b$  as the numbers  $a$  and  $b$ , it is only necessary to repeat the division, dividing the preceding divisor  $b$  by the remainder  $a-nb$ ; and the new remainder which is obtained will still have with the preceding divisor the same greatest common divisor, and so on. Proceeding in this way till we arrive at a division without a remainder, that is, in which the remainder is nothing, let  $p$  be the last divisor contained exactly a certain number of times in its dividend, which will therefore be divisible by  $p$ , and will have the form  $mp$ ; so that the numbers  $p$  and  $mp$  are both divisible by  $p$ , and as no number can be divided by a number greater than itself, it is clear that they have no greater common divisor. Therefore the last divisor is the greatest common divisor of the given numbers  $a$  and  $b$ , and the rule laid down is thus demonstrated.

#### GEOMETRICAL PROPORTION

754. When their ratios are equal, geometrical relations are equal, such equality of relations being called a *geometrical proportion*: thus we write  $a : b = c : d$ , or  $a : b :: c : d$ , thereby indicating that the relation  $a : b$  is equal to the relation  $c : d$ , which is expressed in language  $a$  is to  $b$  as  $c$  to  $d$ . Such a proportion is  $4 : 1 = 12 : 3$ , for the relation of  $4 : 1$  is  $\frac{4}{1}$ , and this also is the relation of  $12 : 3$ . Thus,  $a : b = c : d$  being a geometrical proportion, the ratio is the same on both sides, and  $\frac{a}{b} = \frac{c}{d}$ ; and, reciprocally, if the fractions  $\frac{a}{b}$  and  $\frac{c}{d}$  are equal, we have  $a : b :: c : d$ . Hence, a geometrical proportion consists of four terms, such that the first divided by the second gives the same quotient as the third divided by the fourth; and hence, also, is deduced an important property common to all geometrical proportion, namely, that the product of the first and last term is always equal to the product of the second and third, or, in more simple language, the product of the extremes is equal to the product of the means.

755. To demonstrate this last named property, let us take the geometrical proportion  $a : b = c : d$ , so that  $\frac{a}{b} = \frac{c}{d}$ . Multiplying both these fractions by  $b$ , we obtain  $a = \frac{bc}{d}$ ; and again multiplying both sides by  $d$ , we have  $ad = bc$ . Now,  $ad$  is the product of the extremes,  $bc$  that of the means, and these two products are found to be equal. Reciprocally, when  $a, b, c, d$  are such numbers that the product of the extremes  $a$  and  $d$  are equal to the product of the means  $b$  and  $c$ , we may be certain that they form a geometrical proportion. For, since  $ad = bc$ , we have only to divide both sides by  $bd$ , which gives us  $\frac{ad}{bd} = \frac{bc}{bd}$  or  $\frac{a}{b} = \frac{c}{d}$ , and therefore  $a : b = c : d$ .

756. The transposition of the four terms of a geometrical proportion, as  $a : c = b : d$ , does not destroy the proportion, for the rule being that the product of the extremes is equal to the product of the means, or  $ad = bc$ , we may also say, 1st,  $b : a = d : c$ ; 2d,  $a : c = b : d$ ; 3d,  $d : b = c : a$ ; 4th,  $d : c = b : a$ . Besides these, some others may be deduced from the same proportions  $a : b = c : d$ ; thus we may say  $a + b : a + c = d : c$ ; that is, the first term added to the second is to the first as the third added to the fourth is to the third. So, also,  $a - b : a - c = d : c$ . For, taking the product of the extremes, we have  $ac - bc = ad - bd$ , which leads to the equality  $ad = bc$ .

757. All the proportions deduced from  $a : b = c : d$  may be generally represented as follows:—

$$ma + nb : pa + qb = mc + nd : pc + qd;$$

For the product of the extremes is  $mpac + npbc + mqad + nqbd$ , which, because  $ad = bc$ , becomes  $mpac + npbc + mqbc + nqbd$ . Farther, the product of the means is  $mpac + mqbc + npad + nqbd$ ; or, as  $ad = bc$ , it is  $mpac + mqbc + npbc + nqbd$ ; so that the two products are equal. It is therefore evident that from any geometrical proportion an infinite number of others may be deduced: take, for example,  $9 : 3 = 18 : 6$ , and we may have

$$3 : 9 = 6 : 18; \quad 9 : 18 = 3 : 6; \quad 12 : 9 = 24 : 18; \\ 3 : 3 = 6 : 6; \quad 12 : 24 = 3 : 6; \quad 12 : 3 = 24 : 6;$$

besides many others.

758. Since in every geometrical proportion the products of the extremes and of the means are equal, we may, when the three first terms are known, find the fourth from them. Thus, suppose the three first terms to be  $9 : 3 = 18 :$  the quantity sought. Now the product of the means is  $3 \times 18$ , or 54; the fourth term must therefore be 1, which multiplied into the first will produce that number; if, then, the product 54 of the means be divided by the first term 9, we shall have 6 for the fourth term, and the whole proportion will stand  $9 : 3 = 18 : 6$ . In general, therefore, if the three first terms are  $a : b = c :$  . . . . we put  $d$  for the unknown fourth letter; and since  $ad = bc$ , we divide both sides by  $a$ , and have  $d = \frac{bc}{a}$ ; so that the fourth term  $= \frac{bc}{a}$ , or is found by multiplying the second and third terms and dividing the product by the first term. This is the foundation of the celebrated RULE OF THREE in arithmetic, wherein three numbers are given to find a fourth in geometrical proportion, so that the first may be to the second as the third is to the fourth. And here we must note some peculiar circumstances which follow.

759. If in two proportions the first and third terms are the same, as in  $a : b = c : d$ , and  $a : f = c : g$ , then the two second and the two fourth terms will also be in geometrical proportion, and  $b : d = f : g$ . For the first proportion being transformed into  $a : c = b : d$ , and the second into  $a : c = f : g$ , the relations  $b : d$  and  $f : g$  must be equal, since each of them is equal to the relation  $a : c$ . In numbers, if  $5 : 25 = 3 : 15$ , and  $5 : 40 = 3 : 24$ , we must have  $25 : 40 = 15 : 24$ . But if the two proportions be such that the means of both are the same, then the first terms will be in an inverse proportion to the fourth terms. Thus, if  $a : b = c : d$ , and  $f : b = c : g$ , then  $a : f = g : d$ . In numbers, for example,  $24 : 8 = 9 : 3$ , and  $6 : 8 = 9 : 12$ , we have  $24 : 6 = 12 : 3$ . And the reason is evident, for the first proportion gives  $ad = bc$ ; the second  $fg = bc$ ; therefore  $ad = fg$ , and  $a : f = g : d$ , or  $a : g : f : d$ .

760. If two proportions are given, a new one may always be produced by separately multiplying the first term of the one by the first term of the other, the second by the second, and so on with respect to the other terms. Thus,  $a : b = c : d$  and  $e : f = g : h$  will furnish  $ae : bf = cg : dh$ . For the first gives  $ad = bc$ , and the second  $eh = fg$ , we have also  $adeh = bcfg$ . But  $adeh$  is the product of the extremes, and  $bcfg$  is the product of the means, in the new proportion. So that the two products are equal, and the proportion is true. Let them, for example, be  $8 : 2 = 20 : 5$  and  $6 : 9 = 14 : 21$ ; the combination will be  $6 \times 8 : 2 \times 9 = 20 \times 14 : 5 \times 21$ , or  $48 : 18 = 280 : 105$ .

761. Lastly, if two products are equal,  $ad = bc$ , the equality may be converted into geometrical proportion, for we shall always have one of the factors of the first product in the same proportion to one of the factors of the second product, as the other factor of the second product is to the other factor of the first product; that is, in the present case,  $a : c = b : d$ , or  $a : b = c : d$ . In numbers,  $3 \times 8 = 4 \times 6$ ; and this proportion may be formed  $8 : 4 = 6 : 3$ , or  $3 : 4 = 6 : 8$ .

762. We do not think it necessary to pursue the subject here by examples of the use of proportion, without which the occurrences of common life could scarcely be carried on. Its basis is here explained, and the application must be obvious to the readers of this work.

#### COMPOUND RELATIONS.

763. If we multiply the terms of two or more relations, antecedents by antecedents, and consequents by consequents, *compound relations* are obtained; that is, the relation between the two products is compounded of the relations given. Thus the relations  $a : b$ ,  $c : d$ ,  $e : f$ , give the compound relation  $ace : bdf$ . Each of these three ratios is said to be one of the *roots* of the compound ratio.

764. As a relation continues the same if both its terms are divided by the same number, in order to abridge it, we may greatly facilitate the above composition by observing whether among the first terms some are not found having common divisors with some of the second terms: for if so, those terms are destroyed, and the quotient arising from the division by that common divisor substituted, of which the following is an example. Let the relations given be  $12 : 25$ ,  $28 : 33$ , and  $55 : 56$ .

$$\begin{array}{r} 2, 4, 12 : 25, 5 \\ 28 : 33, 11 \\ 11, 28 : 36, 2 \\ \hline 2 : 5 \end{array}$$

Whence we see that  $2 : 5$  is the compound relation required.

765. The same operation is performed if we are calculating by letters; and a remarkable case occurs, when each antecedent is equal to the consequent in the preceding relation: thus, if the given relations are

$$\begin{array}{l} a : b, \\ b : c, \\ c : d, \\ d : e, \\ e : a, \end{array}$$

**The compound relation is 1 : 1.**

766. We may perceive the utility of these principles by applying them, for instance, to the relation between two rectangular fields, which is compounded of the relations of the lengths and breadths. Let one of them, A, be 500 ft. long and 60 ft. wide, and the other, B, be 360 ft. long and 60 ft. broad; then the relation of the lengths is  $500 : 360$ ; that of the breadths  $60 : 100$ . Thus we have

$$\begin{array}{r} 5, \cancel{500} : \cancel{360}, 6 \\ \quad \quad \cancel{60} : \cancel{180} \\ \hline 5 \quad \quad : \quad \quad 6 \end{array}$$

Whence the field  $A$  is to the field  $B$  as 5 to 6.

767. So, again, if we wish to compare two rooms with respect to their space or contents, we are to recollect that here the relation between them is compounded of three relations, namely, that of the lengths, that of the breadths, and that of the heights. Let the room A be 36 ft. long, 16 ft. broad, and 14 ft. high; and the room B be 42 ft. long, 24 ft. broad, and 10 ft. high; we have the relations as follow:—

	A	B
For the length	<del>6, 36</del> : <del>42, 7</del>	
For the breadth	<del>2, 4, 16</del> : <del>24, 4</del>	
For the height	<del>2, 14</del> : <del>10, 5</del>	
	4	5

So that the capacity of the room A is to that of the room B as 4 to 5.

768. When the relations thus compounded are equal, multiplicate relations result; namely, two equal relations give a *duplicate ratio* or *ratio of the squares*. Three equal relations produce the *triplicate ratio*, or *ratio of the cubes*, and so on. Thus the relations  $a : b$  and  $a : b$  give the compound relation  $aa : bb$ ; whence we say that the squares are in the duplicate ratio of the roots; and the ratio  $a : b$  multiplied thrice, giving the ratio  $a^3 : b^3$ , shows that the cubes are in the triplicate ratio of the roots.

769. From a knowledge of Geometry, we learn that two circular spaces are in the duplicate relation of their diameters; which means, that they are to each other as the squares of their diameters. Suppose A to be such a space, having a diameter = 45 ft.; B another circular space, whose diameter = 30; then the first space will be to the second as  $45 \times 45$  to  $30 \times 30$ , or, compounding the two equal relations,

$$\begin{array}{r} 3, \cancel{9}, 45 : \cancel{30}, \cancel{6}, 2 \\ 3, \cancel{9}, 45 : \cancel{30}, \cancel{6}, 2 \\ \hline 9 : 4 \end{array}$$

Whence we see the two areas are as 9 to 4.

770. Again, it is known that the solid contents of spheres are in the ratio of the cubes of the diameters. Thus, the diameter of a globe, A, being 1 ft., and the diameter of another globe, B, being 2 ft. ; the solid contents of A will be to those of B as  $1^3 : 2^3$ , or as 1 to 8. If, therefore, the spheres are composed of similar substances, the sphere B will weigh 8 times as much as the sphere A.

771. The ratio of two fractions  $\frac{a}{b} : \frac{c}{d}$  may always be expressed in integer numbers, since we have only to multiply the two fractions by  $bd$  to obtain the ratio  $ad : bc$ , which is equal to the other; and if  $ad$  and  $bc$  have common divisors, the ratio may be reduced to less terms. For instance,  $\frac{15}{31} : \frac{25}{24} = 15 \times 24 : 31 \times 25 = 360 : 775$ .

772. Suppose we sought the ratio of the fractions  $\frac{1}{a}$  and  $\frac{1}{b}$ , it is evident we should have  $\frac{1}{a} : \frac{1}{b} = b : a$ , which is expressed by saying that two fractions which have unity for their denominator are in the *reciprocal* or *inverse* ratio of their denominators. So when any two fractions have a common numerator, for  $\frac{c}{a} : \frac{c}{b} = b : a$ . When, however, two fractions have their denominators equal, as  $\frac{a}{c} : \frac{b}{c}$ , they are in the direct ratio of their numerators, that is, as  $a : b$ . Thus,  $\frac{3}{10} : \frac{3}{10} = \frac{6}{10} : \frac{6}{10} = 6 : 6$  and  $\frac{9}{10} : \frac{9}{10} = 9 : 9$ .

773. It is upon the principles here laid down that we are enabled to resolve questions in what is called in books of arithmetic, THE RULE OF FIVE, as, for example, in the following question : — If 25 pence per day be given to a labourer, and it is required to know what must be given to 24 labourers who have worked 50 days, we state it thus : —

$$\begin{array}{r}
 1 : 24 \text{ masons.} \\
 1 : 50 \text{ days.} \\
 \hline
 1 : 1200 = 25 \text{ (pence)} : \dots \text{£}125 \\
 25 \\
 12 \overline{)30000} \\
 20 \overline{)2500} \\
 \hline
 125
 \end{array}$$

GEOMETRICAL PROGRESSION.

774. When the numbers of a series increase or decrease by becoming a certain number of times greater or less, the series is called a *geometrical progression*, because each term is to the following one in the same geometrical ratio. The number expressing how many times each term is greater than the preceding is called the *exponent*: thus, if the first term = 1 and the exponent = 2, the geometrical progression becomes,

Terms 1 2 3 4 5 6 7 8 9 &c  
 Progression 1, 2, 4, 8, 16, 32, 64, 128, 256, &c.

In which the numbers 1, 2, 3, &c. mark the place which each term holds in the progression. Generally, if the first term =  $a$  and the exponent =  $b$ , we have the following geometrical progression —

Terms 1 2 3 4 5 6 7 8 . . .  $n$   
 Progression  $a, ab, ab^2, ab^3, ab^4, ab^5, ab^6, ab^7, \dots ab^{n-1}$ .

Thus, when the progression proceeds to  $n$  terms, the last term is  $= ab^{n-1}$ . If the exponent  $b$  be greater than unity, the terms continue to increase; if the exponent  $b=1$ , the terms are all equal; and, lastly, if the exponent  $b$  be less than 1, or a fraction, the terms continually decrease. So if  $a=1$  and  $b=\frac{1}{2}$ , we have the geometrical progression 1,  $\frac{1}{2}$ ,  $\frac{1}{4}$ ,  $\frac{1}{8}$ ,  $\frac{1}{16}$ ,  $\frac{1}{32}$ ,  $\frac{1}{64}$ ,  $\frac{1}{128}$ , &c., wherein we have for consideration,

FIRST — The first term, which has been called  $a$ .

SECOND — The exponent, which has been called  $b$ .

THIRD — The number of terms  $a$

FOURTH — The last term, which has been found  $= ab^{n-1}$ .

Hence, if any three of these be given, the last term may be found by multiplying the  $n-1$  power of  $b$ , or  $b^{n-1}$ , by the first term  $a$ .

775. If, therefore, in the geometrical progression 1, 2, 4, 8, &c. the fiftieth term be required, we have  $a=1$ ,  $b=2$ , and  $n=50$ , consequently the fiftieth term is  $= 2^{49}$ . Now  $2^9=512$ , and  $2^{10}=1024$ . Wherefore the square of  $2^{20}=1048576$ , and the square of this number or  $1099511627776=2^{40}$ ; and multiplying this value of  $2^{40}$  by  $2^9$  or 512, we have  $2^{49}=562949953421312$ .

776. One of the most usual questions which occur relative to geometrical progression is to find the sum of the terms, the mode of doing which we shall now explain. Let the following progression of ten terms be given: —

1, 2, 4, 8, 16, 32, 64, 128, 256, 512.

We will represent the sum by  $s$ , that is,  $s=1+2+4+8+16+32+64+128+256+512$ . Double both sides and we have  $2s=2+4+8+16+32+64+128+256+512+1024$ . Subtracting from this the progression represented by  $s$  we have  $s=1024-1=1023$ ; wherefore the sum required is 1023.

777. Suppose in the same progression the number of terms is undetermined and  $=n$ , so that the sum in question or  $s=1+2+2^2+2^3+2^4+\dots+2^{n-1}$ . If we multiply by 2 we have  $2s=2+2^2+2^3+2^4+\dots+2^n$ , and subtracting the preceding from the last equation we have  $s=2^n-1$ . Hence we see that the sum required is found by multiplying the last term  $2^{n-1}$  by the exponent 2 in order to have  $2^n$ , and subtracting unity from that product.

778. Suppose, generally, the first term  $=a$ , the exponent  $=b$ , the number of terms  $=n$ , and their sum  $=s$ , so that

$$s = a + ab + ab^2 + ab^3 + ab^4 + \dots + ab^{n-1}.$$

Multiply by  $b$ , and we have

$$bs = ab + ab^2 + ab^3 + ab^4 + ab^5 + \dots + ab^n,$$

and subtracting the first equation, the remainder is  $(b-1)s = ab^n - a$ , whence is easily deduced the sum required,  $s = \frac{ab^n - a}{b-1}$ . Whence it follows that the sum of any geometrical progression may be found by multiplying the last term by the exponent of the progression, subtracting the first term from the product and dividing the remainder by the exponent *minus* unity.

779. Let there be a geometrical progression of seven terms, whereof the first = 3 and the exponent = 2. Then  $a=3$ ,  $b=2$ , and  $n=7$ . The first term will =  $3 \times 2^6$ , or  $3 \times 64 = 192$ , and the progression will be

$$3, 6, 12, 24, 48, 96, 192.$$

Multiplying the last term 192 by the exponent 2 we have 384; subtracting the first term the remainder is 381; and dividing this by  $b-1$  or by 1, we have 381 for the sum of the whole progression.

780. When the exponent is less than 1, and the terms of the progression consequently diminish, the sum of such a decreasing progression, which would go on to infinity, may nevertheless be accurately expressed. Thus, let the first term = 1, the exponent  $\frac{1}{2}$ , and the sum =  $s$ , so that

$$s = 1 + \frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \frac{1}{32} + \frac{1}{64} \&c.$$

Multiply by 2, and we have

$$2s = 2 + 1 + \frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \frac{1}{16} + \frac{1}{32} \&c. \text{ ad infinitum};$$

subtracting the preceding progression the remainder is  $s=2$  for the sum of the proposed infinite progression. In general, suppose the first term =  $a$  and the exponent of the progression =  $\frac{b}{c}$  (a fraction less than 1), and consequently  $c$  is greater than  $b$ , the sum of the progression will be found thus:

$$\text{Make } s = a + \frac{ab}{c} + \frac{ab^2}{c^2} + \frac{ab^3}{c^3} + \frac{ab^4}{c^4} \&c.;$$

multiplying by  $\frac{b}{c}$  we shall have

$$\frac{b}{c}s = \frac{ab}{c} + \frac{ab^2}{c^2} + \frac{ab^3}{c^3} + \frac{ab^4}{c^4} + \&c. \text{ ad infinitum};$$

subtracting, the remainder is  $(1 - \frac{b}{c})s = a$ . Hence  $s = \frac{a}{1 - \frac{b}{c}}$ . Multiplying both terms of the fraction by  $c$  we have  $s = \frac{ac}{c-b}$ . The sum, therefore, of the progression is found by dividing the first term  $a$  by 1 minus the exponent, or by multiplying  $a$  by the denominator of the exponent, and dividing the product by the same denominator, diminished by the numerator of the exponent.

781. So are found the sums of progressions whose terms are alternately affected by the signs + and -. For example:

$$s = a - \frac{ab}{c} + \frac{ab^2}{c^2} - \frac{ab^3}{c^3} + \frac{ab^4}{c^4} - \&c.$$

Multiplying by  $\frac{b}{c}$  we have

$$\frac{b}{c}s = \frac{ab}{c} - \frac{ab^2}{c^2} + \frac{ab^3}{c^3} - \frac{ab^4}{c^4} \&c.$$

Adding to this equation that preceding we obtain  $(1 + \frac{b}{c})s = a$ . Whence the sum required is  $s = \frac{a}{1 + \frac{b}{c}}$ , or  $s = \frac{ac}{c+b}$ . Thus, if the first term  $a = \frac{3}{2}$ , and the exponent =  $\frac{2}{3}$ ; that is to say,  $b=2$  and  $c=3$ , we shall have for the sum of the progression  $\frac{3}{2} + \frac{6}{27} + \frac{12}{27} + \frac{24}{27} + \&c. = 1$ : for by subtracting the exponent from 1 there remains  $\frac{2}{3}$ ; and by dividing and dividing the first term by that remainder the quotient is 1.

782. Suppose the terms were alternately positive and negative, thus —

$$\frac{3}{2} - \frac{6}{27} + \frac{12}{27} - \frac{24}{27} \&c.,$$

the sum will be

$$\frac{a}{1 + \frac{b}{c}} = \frac{\frac{3}{2}}{\frac{5}{6}} = \frac{9}{5}.$$

In the infinite progression,

$$\frac{3}{10} + \frac{3}{100} + \frac{3}{1000} + \frac{3}{10000} + \frac{3}{100000} \&c.$$

the first term is  $\frac{3}{10}$ , and the exponent  $\frac{1}{10}$ . Subtract this last from 1, and the remainder is  $\frac{9}{10}$ . If we divide the first term by this fraction the quotient is  $\frac{1}{3}$  for the sum of the progression; so that by taking only one term of the progression, namely,  $\frac{3}{10}$ , the error is only  $\frac{1}{10}$ . But taking two terms,  $\frac{3}{10} + \frac{3}{100} = \frac{33}{100}$ , there would still be  $\frac{1}{100}$  wanting to make the sum =  $\frac{1}{3}$ .

We shall conclude with another example in the infinite progression: —

$$9 + \frac{9}{10} + \frac{9}{100} + \frac{9}{1000} + \frac{9}{10000} \&c.$$

Here the first term is 9 and the exponent  $\frac{9}{10}$ . Then 1 minus the exponent =  $\frac{9}{10}$  and  $\frac{9}{\frac{9}{10}} = 10$ , the sum required. This series is thus expressed by a decimal fraction 9.9999999, &c.

INFINITE DECIMAL FRACTIONS.

783. It has already been seen that decimal fractions are used in logarithmic calculations, in which vulgar fractions would be useless and cumbersome. In other calculations they are of such importance that we shall here dwell upon them, and show how to transform a vulgar fraction into a decimal, and the converse.

784. Generally let it be required to change the fraction  $\frac{a}{b}$  into a decimal fraction. Now, as this fraction expresses no more than the quotient of  $a$  divided by  $b$ , instead of  $a$  let us write  $a\cdot0000000$ , whose value does not at all differ from  $a$ , since it contains neither tenth nor hundredth parts. Let us divide this by  $b$  by the common rules of division, taking care to put in the proper place the point which separates the decimals and the integers, and the operation is performed. Let the fraction, for example, be equivalent to  $\frac{1}{2}$ , the division in decimals will then stand thus:—

$$\begin{array}{r} 2)1\cdot0000000 \\ \underline{0\cdot5000000} \\ \hline \end{array} = \frac{1}{2}.$$

From this it appears that  $\frac{1}{2} = 0\cdot5000000$  or  $0\cdot5$ ; which is sufficiently manifest, since this decimal fraction represents  $\frac{5}{10}$ , which is the same as  $\frac{1}{2}$ .

785. Let the given fraction be  $\frac{1}{3}$ , and we have

$$\begin{array}{r} 3)1\cdot0000000 \\ \underline{0\cdot3333333} \\ \hline \end{array} = \frac{1}{3}.$$

786. From this it is seen that the decimal fraction equivalent to  $\frac{1}{3}$  cannot be discontinued, but that the number 3 is repeated *ad infinitum*. Indeed, it has been already seen, in the preceding article, that the fractions  $\frac{3}{10} + \frac{3}{100} + \frac{3}{1000} + \frac{3}{10000}$  added together make  $\frac{1}{3}$ . In the same way, the decimal fraction which expresses the value of  $\frac{2}{3}$  is  $0\cdot6666666$ , evidently the double of  $\frac{1}{3}$ .

787. Suppose  $\frac{1}{4}$  to be the proposed fraction, we have

$$\begin{array}{r} 4)1\cdot0000000 \\ \underline{0\cdot2500000} \\ \hline \end{array} = \frac{1}{4};$$

so that  $\frac{1}{4} = 0\cdot2500000$  or  $0\cdot25$ . The proof whereof is that  $\frac{2}{10} + \frac{5}{100} = \frac{25}{100} = \frac{1}{4}$ .

788. In the same way for the fraction  $\frac{3}{4}$ , we have

$$\begin{array}{r} 4)3\cdot0000000 \\ \underline{0\cdot7500000} \\ \hline \end{array} = \frac{3}{4}.$$

Thus we see  $\frac{3}{4} = 0\cdot75$ , that is,  $\frac{7}{10} + \frac{5}{100} = \frac{75}{100} = \frac{3}{4}$ .

789. The fraction  $\frac{5}{4}$  is changed into a decimal fraction by making

$$\begin{array}{r} 4)5\cdot0000000 \\ \underline{1\cdot2500000} \\ \hline \end{array} = \frac{5}{4};$$

for  $1 + \frac{25}{100} = \frac{5}{4}$ .

790. So  $\frac{1}{5}$  will be found  $= 0\cdot2$ ,  $\frac{2}{5} = 0\cdot4$ ,  $\frac{3}{5} = 0\cdot6$ ,  $\frac{4}{5} = 0\cdot8$ ,  $\frac{5}{5} = 1$ ,  $\frac{6}{5} = 1\cdot2$ , &c. In the occurrence of the denominator 7, the decimal fractions become a little more complicated; thus we have  $\frac{1}{7} = 0\cdot142857142857$ , &c., in which the six figures are continually repeated. By transforming this decimal fraction into a geometrical progression, we may see that it precisely expresses the value  $\frac{1}{7}$ , the first term of this progression  $= \frac{142857}{1000000}$ , and the exponent  $= \frac{1}{1000000}$ . Hence the sum  $= \frac{\frac{142857}{1000000}}{1 - \frac{1}{1000000}} = \frac{142857}{1000000} \cdot \frac{1000000}{999999} = \frac{142857}{999999}$  (multiplying both terms by  $1000000$ )  $= \frac{1}{7}$ . There is, however, a simpler mode of proving that this decimal fraction is exactly  $\frac{1}{7}$ , by substituting for its value the letter  $s$ , as under:—

$$\begin{array}{rcl} s & = & 0\cdot142857142857, \text{ \&c.} \\ 10s & = & 1\cdot428571428571, \text{ \&c.} \\ 100s & = & 14\cdot285714285714, \text{ \&c.} \\ 1000s & = & 142\cdot857142857142, \text{ \&c.} \\ 10000s & = & 1428\cdot571428571428, \text{ \&c.} \\ 100000s & = & 14285\cdot714285714285, \text{ \&c.} \\ 1000000s & = & 142857\cdot142857142857, \text{ \&c.} \\ \text{Subtract } s & & 0\cdot142857142857, \text{ \&c.} \\ \hline 999999s & = & 142857 \end{array}$$

Now, dividing by  $999999$ , we shall have  $s = \frac{142857}{999999} = \frac{1}{7}$ ; hence  $s = \frac{1}{7}$ .

791. The same will be seen by trial upon other fractions whose denominator is 7, the decimal fraction being infinite and six figures continually repeated. The reason is, that in continuing the division, we must return to a remainder which has already been had; and in

that division only 6 different numbers can form the remainder, namely, 1, 2, 3, 4, 5, 6; so that after the sixth division the same figures must return.

792. With the denominator 8 we have the following decimal fraction:  $\frac{1}{8}=0\cdot125$ ,  $\frac{2}{8}=0\cdot25$ ,  $\frac{3}{8}=0\cdot375$ ,  $\frac{4}{8}=0\cdot5$ ,  $\frac{5}{8}=0\cdot625$ ,  $\frac{6}{8}=0\cdot75$ ,  $\frac{7}{8}=0\cdot875$ , &c. With 9 for the denominator, we have  $\frac{1}{9}=0\cdot11111$ , &c.;  $\frac{2}{9}=0\cdot22222$ , &c.;  $\frac{3}{9}=0\cdot33333$ , &c. With 10 for the denominator, we have  $\frac{1}{10}=0\cdot1$ ,  $\frac{2}{10}=0\cdot2$ ,  $\frac{3}{10}=0\cdot3$ , which, indeed, is manifest from the nature of the thing; as also that  $\frac{1}{100}$  must be  $0\cdot01$ , and  $\frac{1}{1000}=0\cdot001$ ; that  $\frac{1}{10000}=0\cdot0001$ , and that  $\frac{1}{100000}=0\cdot00001$ . If the denominator be 11, then  $\frac{1}{11}=0\cdot0909090$ , &c. Suppose we desired to know the value of this decimal fraction, call it  $s$ , then

$$\begin{aligned}s &= 0\cdot0909090, \&c. \\ 10s &= 0\cdot9090909, \&c. \\ 100s &= 9\cdot0909090, \&c.\end{aligned}$$

Subtract  $s$ , and we have  $99s=9$ ; consequently  $s=\frac{9}{99}=\frac{1}{11}$ : so with  $\frac{2}{11}$ , &c.

793. There are many of these decimal fractions which are called *recurring*, sometimes with two, and at other times with more, figures. Their values may be found without difficulty. Thus in the case of a single figure constantly repeated, let it be represented by  $a$ , so that  $s=0\cdot aaaaaa$ , we have

$$\begin{array}{r} 10s = a\cdot aaaaaa \\ \text{subtracting } s = 0\cdot aaaaaa \\ \hline\end{array}$$

$$\text{we have } 9s = a, \text{ so that } s = \frac{a}{9}.$$

794. In the case of two figures, as  $ab$ , we shall find  $s = \frac{ab}{99}$ . In the case of three figures, as  $abc$ , we shall have  $s = \frac{abc}{999}$ , and so on.

795. So that if a decimal fraction occurs, it is easy to find its value; for instance, of  $0\cdot296296$ , the value will be  $\frac{296}{999}=\frac{8}{27}$ , which fraction, it may easily be proved, will give again the decimal fraction required.

796. We shall close this section with a curious example of changing into a decimal fraction the vulgar fraction  $\frac{1}{1 \times 2 \times 3 \times 4 \times 5 \times 6 \times 7 \times 8 \times 9 \times 10}$ , the operation whereof is as follows:—

$$\begin{array}{r} 2) 1\cdot00000000000000 \\ 3) 0\cdot50000000000000 \\ 4) 0\cdot16666666666666 \\ 5) 0\cdot04166666666666 \\ 6) 0\cdot00833333333333 \\ 7) 0\cdot00138888888888 \\ 8) 0\cdot00019841269841 \\ 9) 0\cdot00002480158730 \\ 10) 0\cdot00000275573192 \\ \hline 0\cdot00000027557319.\end{array}$$

#### CALCULATION OF INTEREST.

797. Interest, or the value of the use of money, is usually expressed *per cent.*, or after the rate per hundred on the principal lent. Thus, if we put out 500 pounds sterling at 5 per cent., it signifies that for every hundred pounds the lender is to receive five pounds per annum during the continuance of the loan. The solution of this question, which is one merely of *simple interest*, is so obvious, that it is unnecessary further to detain the reader upon it; and we therefore pass on to *compound interest*, or interest upon interest, which arises from the principal and interest taken together, as it becomes due at the end of each stated time of payment.

798. In the resolution of this question, we are to consider that 100*l.* at the end of a year becomes 105*l.* Let  $a$  = principal. Its amount at the end of the year is found by saying, if 100 gives 105, what will  $a$  give; and we answer  $\frac{105a}{100} = \frac{21a}{20}$ , which may be also expressed  $\frac{3}{20} \times a$ , or  $a + \frac{1}{20} \times a$ .

799. Thus, by adding its twentieth part to the original principal, we have the principal at the end of the first year; adding to this last its twentieth, we know the amount of the given principal in two years, and so on. Hence the annual increases to the principal may be easily computed. Suppose, for instance, the principal of 1000*l.* Expressing the values in decimal fractions, it will be worth —

After 1 year	-	-	-	£1050	
				52·5	One year's interest on £1050.
After 2 years	-	-	-	1102·5	
				55·125	— 1102·5
After 3 years	-	-	-	1157·625	
				57·881	— 1157·625
After 4 years	-	-	-	1215·506	
				60·775	— 1215·506
After 5 years	-	-	-	1276·281 &c.	

The method above exhibited would, however, in calculations for a number of years, become very laborious, and it may be abridged in the following manner.

800. Let the present principal =  $a$ ; now, since a principal of 20*l.* will amount to 21*l.* at the end of a year, the principal  $a$  will amount to  $\frac{21}{20} \times a$  at the end of that time. At the end of the following year the same principal will amount to  $\frac{21^2}{20^2} \times a = (\frac{21}{20})^2 \times a$ . This principal of two years will, the year after, amount to  $(\frac{21}{20})^3 \times a$ , which will therefore be the principal of three years; increasing in this manner, at the end of four years the principal becomes  $(\frac{21}{20})^4 \times a$ . After a century it will amount to  $(\frac{21}{20})^{100} \times a$ , and in general  $(\frac{21}{20})^n \times a$  is the amount of the principal after  $n$  years; a formula serving to determine the amount of principal after any number of years.

801. The interest of 5 per cent., which has been taken in the above calculation, determined the fraction  $\frac{21}{20}$ . Had the interest been reckoned at 6 per cent. the principal  $a$  would at the end of a year be  $(\frac{106}{100}) \times a$ ; at the end of two years to  $(\frac{106}{100})^2 \times a$ ; and at the end of  $n$  years to  $(\frac{106}{100})^n \times a$ . Again, if the interest be at 4 per cent. the principal  $a$  will, after  $n$  years, be  $(\frac{104}{100})^n \times a$ . Now all these formulæ are easily resolved by logarithms; for if, according to the first supposition, the question be  $(\frac{21}{20})^n \times a$ , this will be  $L.(\frac{21}{20})^n + L.a$ , and as  $(\frac{21}{20})^n$  is a power, we have  $L.(\frac{21}{20})^n = nL.\frac{21}{20}$ : so that the logarithm of the principal required is  $= n \times L.\frac{21}{20} + L.a$ , and the logarithm of the fraction  $\frac{21}{20} = L.21 - L.20$ .

802. We shall now consider what the principal of 1000*l.* will amount to at compound interest of 5 per cent. at the end of 100 years. Here  $n=100$ . Hence the logarithm of the principal required will be  $= 100L.\frac{21}{20} + L.1000$ , calculated as under:—

$$\begin{array}{r} L.21 = 1 \cdot 3222193 \\ \text{Subtracting } L.20 = 1 \cdot 3010300 \\ \hline L.\frac{21}{20} = 0 \cdot 0211893 \\ \text{Multiply by } 100 \\ \hline 100 L.\frac{21}{20} = 2 \cdot 1189300 \\ \text{Add } L.1000 = 3 \cdot 0000000 \end{array}$$

$5 \cdot 1189300 =$  Logarithm of the principal required; from the characteristic whereof the principal must be a number of six figures, and by the tables it will appear to be 131,501*l.* In the case of a principal of 3452*l.* at 6 per cent. for sixty-four years, we have  $a=3452$  and  $n=64$ . Principal at the end of the first year therefore  $= \frac{106}{100} \times a = \frac{53}{50}$ . Hence the logarithm of the principal sought  $= 64 \times L.\frac{53}{50} + L.3452$ , which will be found to amount to 143,763*l.*

803. When the number of years is very great, errors of considerable magnitude may arise from the logarithms not being sufficiently extended in the decimal places; but as our object here is only to show the principle on which these calculations are founded, we do not think it necessary further to pursue that subject.

804. There is another case which now requires our consideration; it is that of not only adding the interest annually to the principal, but increasing it every year by a new sum  $= b$ . The original principal  $a$  would then increase in the following manner:—

$$\begin{array}{l} \text{After 1 year, } \frac{21}{20}a + b \\ \text{After 2 years, } (\frac{21}{20})^2a + \frac{21}{20}b + b \\ \text{After 3 years, } (\frac{21}{20})^3a + (\frac{21}{20})^2b + \frac{21}{20}b + b \\ \text{After 4 years, } (\frac{21}{20})^4a + (\frac{21}{20})^3b + (\frac{21}{20})^2b + \frac{21}{20}b + b \\ \text{After } n \text{ years, } (\frac{21}{20})^na + (\frac{21}{20})^{n-1}b + (\frac{21}{20})^{n-2}b + \dots + \frac{21}{20}b + b \end{array}$$

This principal evidently consists of two parts, whereof the first  $= (\frac{21}{20})^n a$ , and the other, taken inversely, forms the series  $b + \frac{21}{20}b + (\frac{21}{20})^2b + (\frac{21}{20})^3b + \dots + (\frac{21}{20})^{n-1}b$ . This last series is evidently a geometrical progression, whose exponent  $= \frac{21}{20}$ . Its sum, therefore, will be found by first multiplying the last term  $(\frac{21}{20})^{n-1}b$  by the exponent  $\frac{21}{20}$ , which gives  $(\frac{21}{20})^n b$ . Subtract the first term  $b$ , and we have the remainder  $(\frac{21}{20})^n b - b$ ; and lastly, dividing by the ex-

ponent minus 1, that is, by  $\frac{1}{20}$ , we have the sum required,  $= 20(\frac{31}{30})^n b - 20b$ . Wherefore the principal sought is  $(\frac{31}{30})^n a + 20(\frac{31}{30})^n b - 20b = (\frac{31}{30})^n \times (a + 20b) - 20b$ .

805. To resolve this formula we must separately calculate its first term  $(\frac{31}{30})^n \times (a + 20b)$ , which is  $nL. \frac{31}{30} + L.(a + 20b)$ , for the number which answers to this logarithm in the tables will be the first term, and if from this we subtract  $20b$  we have the principal sought.

806. Suppose a principal of 1000*l.* placed out at 5 per cent. compound interest, and to it there be annually added 100*l.* besides its compound interest, and it be required to know to what it will amount at the end of 25 years. Here  $a=1000$ ,  $b=100$ ,  $n=25$ ; and the operation is as follows:—

$$L. \frac{31}{30} = 0.021189299$$

$$\text{Multiply by 25 we have } 25L. \frac{31}{30} = 0.5297324750$$

$$L.(a + 20b) = 3.4771213135$$

$$= 4.0068537885$$

The first part or number which answers to this logarithm is 10159.1*l.*; from which if we subtract  $20b=2000$  we find the principal in question to be after 25 years 8159.1*l.*

807. If it be required to know in how many years a principal of 1000*l.* under the above conditions would amount to 1,000,000*l.*; let  $n$  be the number of years required, and since  $a=1000$ ,  $b=100$ , the principal at the end of  $n$  years will be  $(\frac{31}{30})^n (3000) - 2000$ , which sum must make 1,000,000*l.*; whence results this equation:—

$$3000 (\frac{31}{30})^n - 2000 = 1000000$$

$$\text{Adding to both sides 2000 we have } 3000 (\frac{31}{30})^n = 1002000$$

$$\text{Dividing both sides by 3000 we have } (\frac{31}{30})^n = 334$$

Using logarithms we have  $nL. \frac{31}{30} = L.334$ , and dividing by  $L. \frac{31}{30}$  we obtain  $n = \frac{L.334}{L. \frac{31}{30}}$ . Now

$L.334 = 2.5237465$  and  $L. \frac{31}{30} = 0.0211893$ , wherefore  $n = \frac{2.5237465}{0.0211893}$ . If, lastly, the two terms

of this fraction be multiplied by 1000000, we shall have  $n = \frac{25237465}{211893}$ , equal to one hundred and nineteen years one month and seven days, which is the time wherein the principal of 1000*l.* will be increased to 1,000,000*l.* In the case of an annual decrease instead of increase of the capital by a certain sum, we shall have the following gradations as the values of  $a$ , year after year, the interest being at 5 per cent., and, representing by  $b$  the sum annually abstracted from the principal,

After 1 year it would be  $\frac{21}{20}a - b$

After 2 years —  $(\frac{21}{20})^2 a - \frac{21}{20}b - b$

After 3 years —  $(\frac{21}{20})^3 a - (\frac{21}{20})^2 b - \frac{21}{20}b - b$

After  $n$  years —  $(\frac{21}{20})^n a - (\frac{21}{20})^{n-1}b - (\frac{21}{20})^{n-2}b - \dots - (\frac{21}{20})b - b$ .

This principal evidently consists of two parts, one whereof is  $(\frac{21}{20})^n a$ , and the other to be subtracted therefrom, taking the terms inversely, forms a geometrical progression, as follows:—

$$b + (\frac{21}{20})b + (\frac{21}{20})^2 b + (\frac{21}{20})^3 b + \dots + (\frac{21}{20})^{n-1}b$$

The sum of this progression has already been found  $= 20(\frac{21}{20})^n b - 20b$ ; if, therefore, this be subtracted from  $(\frac{21}{20})^n a$ , we have the principal required after  $n$  years  $= (\frac{21}{20})^n (a - 20b) + 20b$ .

808. For a less period than a year, the exponent  $n$  becomes a fraction; for example, 1 day  $= \frac{1}{365}$ , 2 days  $= \frac{2}{365}$ , and so on. It often happens that we wish to know the present value of a sum of money payable at the end of a number of years. Thus, as 20 pounds in ready money amount in a twelvemonth to 21 pounds, so, reciprocally, 21 pounds payable at the end of a year can be worth only 20 pounds. Therefore, if  $a$  be a sum payable at the end of a year, the present value of it is  $\frac{20}{21}a$ . Hence, to find the present value of a principal  $a$  at the end of a year, we must multiply by  $\frac{20}{21}$ ; to find its present value at the end of two years, it must be multiplied by  $(\frac{20}{21})^2 a$ ; and, in general, its value  $n$  years before the time of payment will be expressed by  $(\frac{20}{21})^n a$ .

809. Thus, suppose a rent of 100*l.* receivable for 5 years, reckoning interest at 5 per cent., if we would know its value in present money, we have

For £100 due after 1 year, the present value is £95.239

after 2 years — 90.704

after 3 years — 86.385

after 4 years — 82.272

after 5 years — 78.355

Sum of the five terms £432.19*s.* 1*d.*

So that in present money, the value is 432*l.* 19*s.* 1*d.*

810. But for a great number of years such a calculation would become laborious. It may be facilitated as follows:—Let the annual rent  $= a$ , commencing directly and con-

tinuing  $n$  years, it will be worth  $a + (\frac{20}{21})a + (\frac{20}{21})^2a + (\frac{20}{21})^3a + (\frac{20}{21})^4a \dots + (\frac{20}{21})^na$ , which is a geometrical progression whose sum is to be found. We have therefore only to multiply the last term by the exponent, the product whereof is  $(\frac{20}{21})^{n+1}a$ , then subtract the first term, and the remainder is  $(\frac{20}{21})^{n+1}a - a$ . Lastly, dividing by the exponent minus 1, that is,  $-\frac{1}{21}$ , or, which is the same, multiplying by  $-21$ , we have the sum required,  $= -21(\frac{20}{21})^{n+1}a + 21a$ , or  $21a - 21(\frac{20}{21})^{n+1}a$ , the value of which second term is easily calculated by logarithms.

## SOLUTION OF PROBLEMS.

811. The object of algebra, as well as of mathematics generally, being the determination of quantities which were before unknown, this is obtained by an attentive consideration of the conditions given, which are always expressed in known numbers.

812. When a question is to be resolved, the numbers sought are usually represented by the last letters of the alphabet, and the object is then to find, under the conditions, an equality between two quantities. This equality, represented by a formula, is called an *equation*, and enables us to determine the value of the number sought, and thence to resolve the equation. More than one number is often sought, but they are found by equations in the same manner.

813. To illustrate this, let us take the following example: — Twenty persons, men and women, go to a tavern. The men spend 24 shillings, and the women as much; but each man, it appears, has spent 1 shilling more than each woman. What was the number of men and the number of the women?

Let the number of the men  $= x$ ;

That of the women then will be  $= 20 - x$ .

Now, these  $x$  men having spent 24 shillings, each man's share must be  $\frac{24}{x}$  shillings.

Again, the  $20 - x$  women having also spent 24 shillings, the share of each woman is  $\frac{24}{20-x}$  shillings.

But we know that each woman's share is 1 shilling less than that of each man; if, therefore, we subtract 1 from each man's share, we must obtain that of each of the women; consequently  $\frac{24}{x} - 1 = \frac{24}{20-x}$ .

From this last equation we have to find the value of  $x$ . We shall hereafter see that  $x=8$ , which value will correspond to the equation, for  $\frac{24}{8} - 1 = \frac{24}{12}$ , includes the equality  $2=2$ .

814. It is thus seen that an equation consists of two parts separated by the sign of equality  $=$ , showing that the two quantities are equal to one another. It is often necessary to submit them to a great number of transformations, in order to deduce the value of the unknown quantity, and these are founded on the following principles: —

That two quantities remain equal, whether we add to them or subtract from them equal quantities.

That the same obtains whether we multiply or divide them by the same number, or extract their roots of the same degree.

And lastly, if we take the logarithms of the quantities, as in the preceding section.

815. The equations most easily resolved are those in which the unknown quantity does not exceed the first power after the terms of the equation have been properly arranged. These are called *simple equations*, or of the *first degree*. If after the reduction and ordering of an equation, the second power of an unknown quantity is still found, it is called an *equation of the second degree*, and is more difficult to resolve. When the cube of the unknown quantity appears in an equation, it is called one of the *third degree*, and so on.

## RESOLUTION OF SIMPLE EQUATIONS, OR OF THE FIRST DEGREE.

816. When the number sought, or unknown quantity represented by  $x$ , is such that one side only contains that letter, and the other a known number, as  $x=12$ , the value of  $x$  is already found. The object is therefore to arrive at that form, however complicated the equation may be when first formed.

817. To begin with the simplest cases: suppose we have brought an equation to the form  $x+9=16$ ; inspection alone here shows us that  $x=7$ ; and, in general, if we find  $x+a=b$ , where  $a$  and  $b$  express known numbers, we have only to subtract  $a$  from both sides to obtain the equation  $x=b-a$ , which indicates the value of  $x$ .

818. If the equation found be  $x-a=b$ , by adding  $a$  to both sides we obtain the value of  $x=b+a$ .

819. So, if the equation has the form  $x-a=aa+1$ , by adding we have  $x=aa+a+1$ .

820. In the equation  $a-8a=20-6a$ , we find  $x=20-6a+8a$ , or  $x=20+2a$ . And in  $x+6a=20+3a$ , we have  $x=20+3a-6a$ , or  $x=20-3a$ .

821. If the original equation has the form  $x - a + b = c$ , we may begin by adding  $a$  to both sides, which gives  $x + b = c + a$ ; and then subtracting  $b$  from both sides, we have  $x = c + a - b$ . Or we might add  $+a - b$  to both sides, by which we immediately obtain  $x = c + a - b$ . So in the following examples:—

If  $x - 2a + 3b = 0$ , we have  $x = 2a - 3b$ .

If  $x - 3a + 2b = 25 + a + 2b$ , we have  $x = 25 + 4a$ .

If  $x - 9 + 6a = 25 + 2a$ , we have  $x = 34 - 4a$ .

When the equation found has the form  $ax = b$ , it is only necessary to divide the two sides by  $a$ , and we have  $x = \frac{b}{a}$ . But when the equation has the form  $ax + b - c = d$ , the terms that accompany  $ax$  must be made to vanish by adding to both sides  $-b + c$ , and then, dividing the new equation  $ax = d - b + c$  by  $a$ , we have  $x = \frac{d - b + c}{a}$ . The same value would have been found by subtracting  $+b - c$  from the given equation, for we should have had in the same form  $ax = d - b + c$  and  $x = \frac{d - b + c}{a}$ . Hence,

If  $2x + 5 = 17$ , we have  $2x = 12$  and  $x = 6$ .

If  $3x - 8 = 7$ , we have  $3x = 15$  and  $x = 5$ .

If  $4x - 5 - 3a = 15 + 9a$ , we have  $4x = 20 + 12a$ , consequently  $x = 5 + 3a$ .

When the equation has the form  $\frac{x}{a} = b$ , multiply both sides by  $a$ , and we have  $x = ab$ . But if  $\frac{x}{a} + b - c = d$ , we first make  $\frac{x}{a} = d - b + c$ , and then  $x = (d - b + c)a = ad - ab + ac$ .

Let  $\frac{1}{4}x - 3 = 4$ ; then  $\frac{1}{4}x = (4 + 3)7$  and  $x = 14$ .

Let  $\frac{1}{4}x - 1 + 2a = 3 + a$ , we have  $\frac{1}{4}x = 4 - a$ , and  $x = 12 - 3a$ .

Let  $\frac{x}{a-1} - 1 = a$ , we have  $\frac{x}{a-1} = a + 1$ , and  $x = aa - 1$ .

When we have such an equation as  $\frac{ax}{b} = c$ , multiply first by  $b$ , which gives  $ax = bc$ , and then dividing by  $a$ , we have  $x = \frac{bc}{a}$ . If  $\frac{ax}{b} - c = d$ , the equation must first be made to take the form  $\frac{ax}{b} = d + c$ ; after which, multiplying by  $b$ , we have  $ax = bd + bc$ , and then  $x = \frac{bd + bc}{a}$ .

Let  $\frac{3}{4}x - 4 = 1$ , we have  $\frac{3}{4}x = 5$  and  $2x = 15$ ; whence  $x = \frac{15}{2}$ , or  $7\frac{1}{2}$ .

If  $\frac{3}{4}x + \frac{1}{2} = 5$ , we have  $\frac{3}{4}x = 5 - \frac{1}{2} = \frac{9}{2}$ ; whence  $3x = 18$ , and  $x = 6$ .

In the case of two or more terms containing the letter  $x$  either on one or both sides of the equation, the process is as follows:—

822. *First.* If they are on the same side, as in the equation  $x + \frac{1}{2}x + 5 = 11$ , we have  $x + \frac{1}{2}x = 6$ , or  $3x = 12$ ; and, lastly,  $x = 4$ .

Let  $x + \frac{1}{2}x + \frac{1}{3}x = 44$ , to find the value of  $x$ . Multiplying by 3 we have  $4x + \frac{1}{2}x = 132$ . Multiply both sides by 2, and we have  $11x = 264$ ; whence  $x = 24$ . This might have been effected more shortly by beginning with the reduction of the three terms which contain  $x$  to the single term  $\frac{1}{6}x$ , and then dividing the equation  $\frac{1}{6}x = 44$  by 11, we should have had  $\frac{1}{6}x = 4$ , whence  $x = 24$ .

Generally, let  $ax - bx + cx = d$ . It is the same as  $(a - b + c)x = d$ , whence  $x = \frac{d}{a - b + c}$ .

823. *Second.* If there be terms containing  $x$  on both sides of the equation, they must be made to vanish from that side in which it can most easily be done, that is to say, in which there are fewest of them; thus, in the equation  $3x + 2 = x + 10$ ,  $x$  must be first subtracted from both sides, which gives  $2x + 2 = 10$ ; whence  $2x = 8$ , and  $x = 4$ .

Let  $x + 4 = 20 - x$ , it is evident that  $2x + 4 = 20$ , and thence  $2x = 16$ , and  $x = 8$ .

Let  $x + 8 = 32 - 3x$ , we have  $4x + 8 = 32$ , then  $4x = 24$ , and  $x = 6$ .

Let  $15 - x = 20 - 2x$ , we have then  $15 + x = 20$ , and  $x = 5$ .

Let  $1 + x = 5 - \frac{1}{2}x$ , we have  $1 + \frac{3}{2}x = 5$ , and  $\frac{3}{2}x = 4$ ;  $3x = 8$ ; and, lastly,  $x = \frac{8}{3} = 2\frac{2}{3}$ .

If  $\frac{1}{2} - \frac{1}{3}x = \frac{1}{4} - \frac{1}{2}x$ , we must add  $\frac{1}{2}x$ , which gives  $\frac{1}{2} = \frac{1}{4} + \frac{1}{2}x$ ; subtracting  $\frac{1}{4}$ , there will remain  $\frac{1}{4} = \frac{1}{2}x$ , and multiplying by 12, we have  $x = 2$ .

If an equation occurs wherein the unknown number  $x$  is a denominator, we must make the fraction vanish by multiplying the whole equation by that denominator. Thus in the equation  $\frac{100}{x} - 8 = 12$ , we must first add 8, and we have  $\frac{100}{x} = 20$ ; then, multiplying by  $x$ , we have  $100 = 20x$ , and dividing by 20,  $x = 5$ .

Let  $\frac{5x+3}{x-1} = 7$ . Multiplying by  $x - 1$ , we have  $5x + 3 = 7x - 7$ .

Subtracting  $5x$ , there remains  $3 = 2x - 7$ . Adding 7, we have  $2x = 10$ ; whence  $x = 5$ .

Radical signs are not unfrequently found in equations of the first degree. For example, a number  $x$  below 100 is required such that the square root of  $100 - x = 8$ , or  $\sqrt{100 - x} = 8$ ; the square of both sides is  $100 - x = 64$ ; adding  $x$  we have  $100 = 64 + x$ , whence we have  $x = 100 - 64 = 36$ .

824. The unknown number  $x$  is sometimes found in the exponents; in this case, recourse must be had to logarithms. Thus  $2^x = 512$ ; taking the logarithms on both sides we have  $x \cdot L.2 = L.512$ , and dividing by  $L.2$ , we find  $x = \frac{L.512}{L.2}$ . We shall here subjoin a few examples of the resolutions of simple equations.

- (1.) Divide 7 into two such parts that the greater may exceed the less by 3.

Let the greater part  $=x$ ,

The less will be  $=7-x$ .

So that  $x=7-x+3$ , or  $x=10-x$ .

Adding  $x$ , we have  $2x=10$ , and dividing by 2,  $x=5$ .

The greater part is 5, and the less is 2.

- (2.) Divide the number 1600 into three such parts that the greatest shall be 200 more than the second, and the second 100 more than the third.

Let the third part  $=x$ , then the second will be  $=x+100$ , and the greatest  $=x+300$ .

These parts, then, make up the number 1600; we have therefore —

$$3x+400=1600; 3x=1200; \text{ and } x=400.$$

The third part, therefore, is 400, the second 500, and the greatest 700.

- (3.) Divide 32 into two such parts that if the less be divided by 6, and the greater by 5, the two quotients taken together may make 6.

Let the less of the two parts sought  $=x$ . The greater will be  $32-x$ .

The first, divided by 6, gives  $\frac{x}{6}$ ; the second, divided by 5, gives  $\frac{32-x}{5}$ .

Now,  $\frac{x}{6} + \frac{32-x}{5} = 6$ ; multiplying them by 5, we have  $\frac{5}{6}x + 32 - x = 30$ , or  $-\frac{1}{6}x + 32 = 30$ .

Adding  $\frac{1}{6}x$ , we have  $32 = 30 + \frac{1}{6}x$ .

Subtracting 30, there remains  $2 = \frac{1}{6}x$ .

Multiplying by 6, we have  $x=12$ . Wherefore the lesser part  $=12$ , the greater  $=20$ .

- (4.) Divide 25 into two such parts that the greater may contain the less 49 times.

Let the less part  $=x$ , then the greater will be  $25-x$ .

The latter, divided by the former, ought to give the quotient 49; therefore

$$\frac{25-x}{x} = 49.$$

Multiplying by  $x$  we have  $25-x=49x$ . Adding  $x$ ,  $25=50x$ .

Dividing by 50,  $x=\frac{1}{2}$ . Hence the less of the two numbers sought is  $\frac{1}{2}$ , and the greater  $24\frac{1}{2}$ .

- (5.) To find such a number that if 1 be subtracted from its double, and the remainder be doubled, 2 subtracted, and the remainder divided by 4, the number resulting from these operations shall be 1 less than the number sought.

Suppose the number to be  $=x$ ; the double  $=2x$ .

Subtracting 1, the remainder is  $2x-1$ ; doubling this, we have  $4x-2$ .

Subtracting 2, the remainder is  $4x-4$ ; dividing by 4 we have  $x-1$ , and this must be 1 less than  $x$ , so that  $x-1=x-1$ . But this is what is called an *identical equation*, showing that  $x$  is indeterminate, or that any number whatever may be substituted for it.

- (6.) What sum is that, into how many equal parts is it divided, and what is the amount of each part, wherein

The first part  $=100$ , and one tenth of the remainder;

The second part  $=200$ , and one tenth of the then remainder;

The third part  $=300$ , and one tenth of the then remainder;

The fourth part  $=400$ , and one tenth of the then remainder; and so on?

Suppose the total sum  $=z$ . Then, since all the parts are equal, let each  $=x$ , by which means the number of parts will be expressed by  $\frac{z}{x}$ . This being established, the solution is as follows:—

Total sum.	Order of the parts.	Amount of each part.	Differences.
$z$	First	$x=100 + \frac{z-100}{10}$	
$z-x$	Second	$x=200 + \frac{z-x-200}{10}$	$100 - \frac{z-100}{10} = 0$
$z-2x$	Third	$x=300 + \frac{z-2x-300}{10}$	$100 - \frac{z-100}{10} = 0$
$z-3x$	Fourth	$x=400 + \frac{z+3x-400}{10}$	$100 - \frac{z-100}{10} = 0$
$z-4x$	Fifth	$x=500 + \frac{z+4x-500}{10}$	$100 - \frac{z-100}{10} = 0$
$z-5x$	Sixth	$x=600 + \frac{z+5x-600}{10}$	and so on.

The differences in the last column are obtained by subtracting each part from that which follows, and all the portions being equal, the differences should be  $=0$ ; and as they are expressed exactly alike, it will be sufficient to make one of them equal to nothing, and we have the equation  $100 - \frac{z-100}{10} = 0$ . Multiplying by 10, we have  $1000 - z + 100 = 0$ , or  $900 - z = 0$ ; consequently  $z=900$ . From this, therefore, we know that each part is 900; and taking any one of the equations in the third column, the first for example, it becomes, by substituting the value of  $x$ ,  $900 = 100 + \frac{z-100}{10}$ , whence the value of  $z$  is obtained; for we

have  $9000 = 1000 + z - 100$ , or  $9000 = 900 + z$ ; whence  $z = 8100$ , and consequently  $\frac{z}{x} = 9$ . Hence the number 8100, and each part = 900 and the number of the parts = 9.

#### RESOLUTION OF TWO OR MORE EQUATIONS OF THE FIRST DEGREE.

825. It often occurs that we are obliged to introduce two or more unknown quantities into algebraic calculations, and these are represented by the letters  $x, y, z$ . If the question is determinate, we arrive at the same number of equations from whence to deduce the unknown quantities. Considering only those equations which contain no powers of an unknown quantity higher than the first, and no products of two or more unknown quantities, it is evident that these equations will have the form  $ax + by + cz = d$ .

826. Beginning with two equations, we will endeavour to find from them the values of  $x$  and  $y$ ; and that the case may be considered in a general manner, let the two equations be — I.  $ax + by = c$ ; and, II.  $fx + gy = h$ , in which  $a, b, c$ , and  $f, g, h$ , are known numbers; it is required from these two equations to obtain the two unknown quantities  $x$  and  $y$ . The most obvious way of proceeding is to determine from both equations the value of one of the unknown quantities,  $x$  for example, and to consider the equality of the two values; for then we obtain an equation in which the unknown quantity  $y$  appears by itself, and may be determined by the rules we have already given. Knowing  $y$ , we have only to substitute its value in one of the quantities that express  $x$ .

827. According to this rule we obtain from the first equation  $x = \frac{c-by}{a}$ , from the second  $x = \frac{h-gy}{f}$ . Stating these two values equal to one another, a new equation appears, —

$$\frac{c-by}{a} = \frac{h-gy}{f}.$$

Multiplying by  $a$ , the product is  $c-by = \frac{ah-agy}{f}$ ; multiplying by  $f$ , the product is  $fc-fby = ah-agy$ . Adding  $agy$ , we have  $fc-fby+agy=ah$ ; subtracting  $fc$ , there remains  $-fby+agy=ah-fc$ ; or  $(ag-bf)y=ah-fc$ ; lastly, dividing by  $ag-bf$ , we have  $y = \frac{ah-fc}{ag-bf}$ .

828. In order to substitute this value of  $y$  in one of those we have found of  $x$ , as in the first, when  $x = \frac{c-by}{a}$ , we shall first have  $-by = \frac{abh+bcf}{ag-bf}$ ; whence  $c-by = c - \frac{abh+bcf}{ag-bf}$ , or  $c-by = \frac{acg-bcf-abh+bcf}{ag-bf} = \frac{acg-abh}{ag-bf}$ ; and dividing by  $a$ ,  $x = \frac{c-by}{a} = \frac{cg-bh}{ag-bf}$ .

829. To illustrate this method, let it be proposed to find two numbers whose sum may be = 15, and difference = 7.

Let the greater number =  $x$ , and the less  $y$ ; we shall then have,

$$\text{I. } x+y=15, \text{ and II. } x-y=7.$$

The first equation gives  $x=15-y$ , and the second  $x=7+y$ ; whence there results the new equation  $15-y=7+y$ . So that  $15=7+2y$ ,  $2y=8$ , and  $y=4$ ; by which means we find  $x=11$ . The less number, therefore, is 4, and the greater is 11.

830. When there are three unknown numbers, and as many equations, as, for example, I.  $x+y-z=8$ ; II.  $x+z-y=9$ ; III.  $y+z-x=10$ ; a value of  $x$  is to be deduced from each: and from I. we have  $x=8+z-y$ ; from II.,  $x=9+y-z$ ; and from III.  $x=y+z-10$ . Comparing them together, we have the following equations:

$$\text{I. } 8+z-y=9+y-z. \quad \text{II. } 8+z-y=y+z-10.$$

The first gives  $2z-2y=1$ ; the second,  $2y=18$ , or  $y=9$ . Substitute this value of  $y$  in  $2z-2y=$ , and we have  $2z-18=1$ , and  $2z=19$ , so that  $z=9\frac{1}{2}$ . We have, therefore, only to determine  $x$ , which is found =  $8\frac{1}{2}$ . The letter  $z$  thus vanishes in the last equation, and the value of  $y$  is immediately found; otherwise we must have had two equations between  $z$  and  $y$  to have been resolved by the preceding rule.

831. Suppose we had found the three following equations —

$$\text{I. } 3x+5y-4z=25. \quad \text{II. } 5x-2y+3z=46. \quad \text{III. } 3y+5z-x=62.$$

Deducing from each the value of  $x$ , we have

$$\text{I. } x = \frac{25-5y+4z}{3}, \quad \text{II. } x = \frac{46+2y-3z}{5}, \quad \text{III. } x = 3y+5z-62.$$

And comparing these three values together, and the third with the first, we have  $3y+5z-62 = \frac{25-5y+4z}{3}$ . Multiplying by 3,  $9y+15z-186=25-5y+4z$ ; so that  $9y+15z=211-5y+4z$ , and  $14y+11z=211$ . Comparing the third with the second, we have  $3y+5z-62 = \frac{46+2y-3z}{5}$ , or  $46+2y-3z=15y+25z-310$ , which, reduced, is  $356=13y+28z$ . From these two new equations the value of  $y$  may be deduced.

$$\text{I. } 211=14y+11z; \text{ whence } 14y=211-11z, \text{ and } y=\frac{211-11z}{14}.$$

$$\text{II. } 356=13y+28z; \text{ whence } 13y=356-28z, \text{ and } y=\frac{356-28z}{13}.$$

These two values form the new equation  $\frac{211-11z}{14} = \frac{356-28z}{13}$ , which becomes  $2743-143z = 4984-392z$ , or  $249z = 2241$ ; whence  $z = 9$ . This value being substituted in one of the two equations of  $y$  and  $z$ , we find  $y = 8$ , and by a similar substitution in one of the three values of  $x$ ,  $x = 7$ .

832. If more than three unknown quantities are to be determined, and as many equations to be resolved, the same manner must be pursued; but the calculations are often tedious; and it is to be observed that in each particular case means may be resorted to for facilitating the resolution. These consist in introducing, besides the principal unknown quantities, some new one, arbitrarily assumed; such, for instance, as the sum of all the rest. But practice only can teach this; and the architect is in this, and remaining pages of this chapter, as much informed on the subject as his practice is likely ever to require.

#### RESOLUTION OF PURE QUADRATIC EQUATIONS.

833. If an equation contains the square or second power of the unknown quantity without any of the higher powers, it is said to be of the second degree. An equation containing the third power of the unknown quantity belongs to cubic equations, and its resolution requires particular rules. There are, therefore, only three kinds of terms in an equation of the second degree.

I. The terms which do not contain the unknown quantity at all, or which contain only known numbers.

II. The terms wherein only the first power of the unknown quantity is found.

III. The terms which contain the square, or second power of the unknown quantity. Thus,  $x$  signifying an unknown quantity, and the letters  $a, b, c, d$ , &c. being known numbers, the terms of the first kind will have the form  $a$ , those of the second kind will have the form  $bx$ , and those of the third kind will have the form  $cx^2$ .

834. It has been already seen that two or more terms of the same kind may be united together and considered as a single term; thus the formula  $axx - bxx + cxx$  may be considered as a single term if thus represented  $(a - b + c)xx$ ; since, in fact,  $(a - b + c)$  is a known quantity. When such terms are found on both sides the sign  $=$ , we have seen they may be brought to one side, and then reduced to a single term. For example, in the equation

$$2xx - 3x + 4 = 5xx - 8x + 11;$$

We first subtract  $2xx$ , and the remainder is

$$-3x + 4 = 5xx - 8x + 11.$$

Then adding  $8x$ , we have

$$5x + 4 = 5xx + 11.$$

Lastly, subtracting 11, the remainder is  $3xx = 5x - 7$ .

835. All the terms may also be brought to one side of the sign  $=$ , leaving only 0 on the other. Thus, the above equation, remembering to change the signs, will assume this form,  $3xx - 5x + 7 = 0$ . Hence, the following general formula represents all equations of the second degree —

$$axx \pm bx \pm c = 0,$$

wherein the sign  $\pm$  is read plus or minus, and shows that the terms to which it is prefixed may be positive or negative. To this formula all quadratic equations may be reduced. Suppose, for instance, the equation

$$\frac{ax+b}{cx+d} = \frac{cx+f}{gx+h}$$

The fractions must be first destroyed. Multiplying for this purpose by  $cx + d$ , we have  $ax + b = \frac{cex + cf + cdx + fd}{gx + h}$ ; then, by  $gx + h$ , we have  $agxx + bgx + ahx + bh = cexx + cfx + edx + fd$ , an equation of the second degree, and one which may be reduced to the three following terms, which are transposed by arrangement in the usual manner: —

$$\begin{aligned} 0 &= agxx + bgx + bh \\ &\quad - cexx + ahx - fd \\ &\quad - cfx \\ &\quad - edx. \end{aligned}$$

This equation is, perhaps, more clearly exhibited in the following form: —

$$0 = (ag - ce)xx + (bg + ah - cf - ed)x + bh - fd.$$

836. Equations of the second degree are called *complete* when the three kinds of terms are found in them, and their resolution is more difficult: on which account we shall first consider those in which one of the terms is wanting. If the term  $xx$  be not found in the equation, it is not a quadratic, but belongs to those whereof we have already treated. If the term containing known numbers only were wanting, the equation would have the form  $axx \pm bx = 0$ , which, being divisible by  $x$ , may be reduced to  $ax \pm b = 0$ , which, also, is a simple equation, not belonging to the present class

837. When the middle term which contains the first power of  $x$  is wanting, the equation assumes the form  $axx \pm c = 0$ , or  $axx = \mp c$ , as the sign of  $c$  is positive or negative. Such an equation is called a *pure* equation of the second degree, since its resolution is without difficulty, for we have only to divide by  $a$ , which gives  $xx = \frac{c}{a}$ ; and, taking the square root of both sides, we have  $x = \sqrt{\frac{c}{a}}$ , which resolves the equation.

838. Three cases are however to be considered; I. when  $\frac{c}{a}$  is a square number (whereof, therefore, the root can be assigned) we obtain for the value of  $x$  a rational number, either integer or fractional. Thus,  $xx = 144$  gives  $x = 12$ ; and  $xx = \frac{9}{16}$  gives  $x = \frac{3}{4}$ . II. When  $\frac{c}{a}$  is not a square, in which case the sign  $\sqrt{\phantom{x}}$  must be used. If, for example,  $xx = 12x = \sqrt{12}$ , the value whereof may be determined by approximation, as heretofore shown. III. When  $\frac{c}{a}$  becomes a negative number, then the value of  $x$  is altogether impossible and imaginary; this result, indeed, proves the question, that such an equation is in itself impossible.

839. It must be here observed, that whenever the extraction of the square root is required the root has two values, the one negative, the other positive. Take the equation  $xx = 49$ , the value of  $x$  is as well  $-7$  as  $+7$ , which is expressed by  $\pm 7$ . Hence all these questions admit of a double answer; but it will easily be perceived that there are many cases in which a negative value cannot exist.

840. In such equations as  $axx = bx$ , where the known quantity  $c$  is wanting, two values of  $x$  may exist, though dividing by  $x$  we only find one. Thus, in the equation  $xx = 3x$ , wherein a value of  $x$  is required, such that  $xx$  may become  $= 3x$ . This is done by supposing  $x = 3$ , a value found by dividing the equation by  $x$ . Besides this value, however, there is another equally satisfactory, namely,  $x = 0$ , for then  $xx = 0$ , and  $3x = 0$ . Thus equations of the second degree admit of two solutions, whilst simple equations admit only of one.

841. We here submit three examples for the illustration of pure equations of the second degree.

I. Find a number the half whereof multiplied by the third produces 24.

Let the number  $= x$ .  $\frac{1}{2}x$  multiplied by  $\frac{1}{3}x$  must produce 24. Therefore  $\frac{1}{6}xx = 24$ . Multiplying by 6 we have  $xx = 144$ , and the root extracted gives  $x = \pm 12$ . We put  $\pm 12$ ; for if  $x = +12$ , we have  $\frac{1}{2}x = 6$  and  $\frac{1}{3}x = 4$ , and the product of these quantities is 24. If  $x = -12$ , we have  $\frac{1}{2}x = -6$ , and  $\frac{1}{3}x = -4$ ; the product of which is likewise 24.

II. Find a number such that by adding 5 to it and subtracting 5 from it the product of the sum by the difference would be 96.

Let the number be  $x$ . Then  $x + 5$  multiplied by  $x - 5$  must give 96. Therefore  $xx - 25 = 96$ .

Adding 25 we have  $xx = 121$ , and extracting the root we have  $x = 11$ .

Thus  $x + 5 = 16$ , and  $x - 5 = 6$ , and lastly,  $6 \times 16 = 96$ .

III. Find a number such that by adding it to 10 and subtracting it from 10 the sum multiplied by the remainder or difference will give 51.

Let the number  $= x$ . Then  $10 + x$  multiplied by  $10 - x$  must make 51. So that  $100 - xx = 51$ .

Adding  $xx$ , and subtracting 51, we have  $xx = 49$ ; the square whereof gives  $x = 7$ .

#### RESOLUTION OF MIXED EQUATIONS OF THE SECOND DEGREE.

842. If three kinds of terms are found in an equation of the second degree, namely, — I. That which contains the square of the unknown quantity, as  $axx$ ; II. That in which the unknown quantity is only known in the first power, as  $bx$ ; III. The kind of terms composed of known quantities only, — such an equation is said to be *mixed* or complete; since two or more terms of the same kind may be brought into one, and all the terms may be brought to one side of the sign  $=$ . The general form of a mixed equation of the second degree will be

$$axx \mp bx \mp c = 0.$$

And we now propose to show how the value of  $x$  may be derived from such an equation; which may be done in two ways.

843. Such an equation may be by division reduced to such a form that the first term may contain only the square  $xx$  of the unknown quantity  $x$ . Leaving the second term on the same side with  $x$ , we will transpose the known term to the other side of the sign  $=$ . Thus the equation assumes the form  $xx \pm px = \pm q$ , in which  $p$  and  $q$  represent any known numbers, positive or negative; and all we have to do is to find the true value of  $x$ . Now if  $xx + px$  were a real square, no difficulty would attend the solution; because it would only be required to take the square root on both sides. It is, however, evident that  $xx + px$  cannot be a square; for we have already seen that if a root consists of two terms, for example  $x + n$ , its square must contain three terms, namely, twice the product of the two parts, besides the square of each part; that is, the square of  $x + n$  is  $xx + 2nx + nn$ . Having,

then, already on one side  $xx + px$ , we may consider  $xx$  as the square of the first part of the root, and in this case  $px$  must represent twice the product of the first part of the root by the second part, whence the second part must be  $\frac{1}{2}p$ ; and indeed the square of  $x + \frac{1}{2}p$  is found to be  $xx + px + \frac{1}{4}pp$ . Now this last being a real square, which has for its root  $x + \frac{1}{2}p$ , if we resume the equation  $xx + px = q$ , we have only to add  $\frac{1}{4}pp$  to both sides, and we obtain  $xx + px + \frac{1}{4}pp = q + \frac{1}{4}pp$ , the first side being a square and the other containing only known quantities. Taking, therefore, the square root of both sides, we find  $x + \frac{1}{2}p = \sqrt{\frac{1}{4}pp + q}$ ; and subtracting  $\frac{1}{2}p$ , we obtain  $x = -\frac{1}{2}p + \sqrt{\frac{1}{4}pp + q}$ ; and as every square root is positive or negative, we shall have for  $x$  two values, thus expressed—

$$x = -\frac{1}{2}p \pm \sqrt{\frac{1}{4}pp + q}.$$

This formula contains the rule whereby all quadratic equations may be resolved, and it should be well remembered, so that it may not be necessary to repeat it. The equation may be always arranged in such a manner that the pure square  $xx$  may be found on one side, and the above equation have the form  $xx = -px + q$ , where it is evident that  $x = -\frac{1}{2}p \pm \sqrt{\frac{1}{4}pp + q}$ .

844. The general rule deduced, therefore, to resolve the equation  $xx = -px + q$ , depends upon the consideration that the unknown quantity  $x$  is equal to half the coefficient or multiplier of  $x$  on the other side of the equation, *plus* or *minus* the square root of the square of this number, and the known quantity which forms the third term of the equation.

845. Thus, having the equation  $xx = 6x + 7$ , we should immediately say that  $x = 3 \pm \sqrt{9 + 7} = 3 \pm 4$ , when we have for values of  $x$ , I.  $x = 7$ ; II.  $x = -1$ . So, also, the equation  $xx = 10x - 9$  would give  $x = 5 \pm \sqrt{25 - 9} = 5 \pm 4$ ; that is, the two values of  $x$  are 9 and 1. The rule will be better understood by the arrangement under the following cases:—

I. Let  $p$  be an even number, and the equation such that  $xx = 2px + q$ , we shall, in that case, have  $x = p \pm \sqrt{pp + q}$ .

II. Let  $p$  be an odd number, and the equation  $xx = px + q$ ; we shall here have  $x = p \pm \sqrt{\frac{1}{4}pp + q}$ ; and since  $\frac{1}{4}pp + q = \frac{pp + 4q}{4}$ , we may extract the square root of the denominator, and write  $x = \frac{1}{2}p \pm \sqrt{\frac{pp + 4q}{4}} = \frac{p \pm \sqrt{pp + 4q}}{2}$ .

III. Lastly, if  $p$  be a fraction, the equation may be resolved in the following manner.

Let it be  $axx = bx + c$ , or  $xx = \frac{bx}{a} + \frac{c}{a}$ , and we shall have by the rule  $x = \frac{b}{2a} \pm \sqrt{\frac{b^2}{4aa} + \frac{c}{a}}$ . Now  $\frac{b^2}{4aa} + \frac{c}{a} = \frac{bb + 4ac}{4aa}$ , the denominator of which is a square, so that  $x = \frac{b \pm \sqrt{bb + 4ac}}{2a}$ .

The other method of resolving mixed quadratic equations is to transform them into pure equations, which is effected by substitution; thus, in the equation  $xx = px + q$ , we write another unknown quantity  $y$ , instead of the unknown quantity  $x$ , such that  $x = y + \frac{1}{2}p$ , by which, when  $y$  is found, the value of  $x$  may be readily determined.

846. Making this substitution of  $y + \frac{1}{2}p$  instead of  $x$ , we have  $xx = yy + py + \frac{1}{4}pp$ , and  $px = py + \frac{1}{2}pp$ ; hence our equation becomes  $yy + py + \frac{1}{4}pp = py + \frac{1}{2}pp + q$ , which is first reduced by subtracting  $py$  to  $yy + \frac{1}{4}pp = \frac{1}{2}pp + q$ ; and then by subtracting  $\frac{1}{4}pp$  to  $yy = \frac{1}{4}pp + q$ . This is a pure quadratic equation, which directly gives  $y = \pm \sqrt{\frac{1}{4}pp + q}$ . And since  $x = y + \frac{1}{2}p$ , we have  $x = \frac{1}{2}p \pm \sqrt{\frac{1}{4}pp + q}$  as before. We shall now illustrate the rule by some examples.

I. What are those two numbers, one whereof exceeds the other by 6, and whose product is 91?

If the less be  $= x$ , the other is  $x + 6$ , and their product  $xx + 6x = 91$ .

Subtracting  $6x$ , the remainder is  $xx = 91 - 6x$ , and the rule gives

$$x = -3 \pm \sqrt{9 + 91} = -3 \pm 10; \text{ so that } x = 7, \text{ and } x = -13.$$

The question admits of two solutions: by one, the less number  $x = 7$ , and the greater  $x + 6 = 13$ ; by the other, the less number  $x = -13$ , and the greater  $x + 6 = -7$ .

II. Find a number from whose square if 9 be taken, the remainder is a number as many units greater than 100 as the number sought is less than 23.

Let the number sought  $= x$ . We know that  $xx - 9$  exceeds 100 by  $xx - 109$ , and since  $x$  is less than 23 by  $23 - x$ , we have the equation  $xx - 109 = 23 - x$ .

Wherefore  $xx = -x + 132$ , and by the rule  $x = -\frac{1}{2} \pm \sqrt{\frac{1}{4} + 132} = -\frac{1}{2} \pm \sqrt{\frac{529}{4}} = -\frac{1}{2} \pm 23$ .

So that  $x = 11$ , and  $x = -12$ .

If, then, a positive number be required, the number is 11, the square of which *minus* 9 is 112, and, consequently, greater than 100 by 12, in the same manner as 11 is less than 23 by 12.

III. To find two numbers in a double ratio to each other, such that if we add their sum to their product we may obtain 90.

Let one of the numbers  $= x$ . Then the other will be  $= 2x$ , their product also  $= 2xx$ . If we add to this  $3x$ , or their sum, the new sum should make 90. So that  $2xx + 3x = 90$ ,  $2xx = 90 - 3x$ , and  $xx = -\frac{3}{2} + 45$ ; whence we obtain

$$x = -\frac{3}{4} \pm \sqrt{\frac{9}{16} + 45} = -\frac{3}{4} \pm \frac{27}{4};$$

consequently  $x = 6$ , or  $-7\frac{1}{4}$ .

IV. To find such a number that if its half be multiplied by its third, and to the product half the number required be added, the result will be 30.

Let the number  $= x$ . Its half multiplied by its third will make  $\frac{1}{6}xx$ , so that  $\frac{1}{6}xx + \frac{1}{2}x = 30$ .

Multiply by 6, and we obtain  $xx + 3x = 180$ , or  $xx = -3x + 180$ , which gives

$$x = -\frac{3}{2} \pm \sqrt{\frac{9}{4} + 180} = -\frac{3}{2} \pm \frac{27}{2};$$

consequently  $x$  is either  $= 12$ , or  $-15$ .

#### PURE EQUATIONS OF THE THIRD DEGREE.

847. An equation of the third degree is *pure* when the cube of the unknown quantity is equal to a known quantity, and neither the square of the unknown quantity nor the unknown quantity itself is found in the equation.

$x^3 = 125$ ; or, more generally,  $x^3 = a$ ,  $x^3 = \frac{a}{b}$  are such equations.

The method of deducing the value of  $x$  from such an equation is obvious, for we have only to extract the cube root on both sides. Thus the equation  $x^3 = 125$  gives  $x = 5$ ; the equation  $x^3 = a$  gives  $x = \sqrt[3]{a}$ ; and the equation  $x^3 = \frac{a}{b}$  gives  $x = \sqrt[3]{\frac{a}{b}}$ , or  $x = \frac{\sqrt[3]{a}}{\sqrt[3]{b}}$ . To resolve such equations it is only necessary to know how to extract the cube root of a given number. In this way, however, we obtain only one value for  $x$ ; but as every equation of the second degree has two values, we have reason to suspect that an equation of the third degree has also more than one value. To investigate this is the object of what follows.

848. Let us, then, take the example  $x^3 = 8$  to find from it the numbers whose cube  $= 8$ . As  $x = 2$  is such a number,  $x^3 - 8 = 0$ , and must be divisible by  $x - 2$ . The division is as follows:—

$$\begin{array}{r} x-2 \overline{) x^3 - 8} \\ \underline{x^3 - 2xx} \phantom{+ 4} \\ 2xx - 8 \\ \underline{2xx - 4x} \phantom{+ 4} \\ 4x - 8 \\ \underline{4x - 8} \\ 0 \end{array}$$

Hence it follows that the equation  $x^3 - 8 = 0$  may be represented by these factors,—

$$(x-2) + (xx + 2x + 4) = 0.$$

The question then is, what number is to be substituted for  $x$  in order that  $x^3 = 8$ , or that  $x^3 - 8 = 0$ ; and it is manifest that the condition is answered by supposing the product just found to be equal to 0. This, however, occurs not only when the first factor  $x - 2 = 0$ , whence we have  $x = 2$ ; but also when the second factor  $xx + 2x + 4 = 0$ . We will therefore make  $xx + 2x + 4 = 0$ , and we shall have  $xx = -2x - 4$ ; and thence  $x = -1 \pm \sqrt{-3}$ . From which we learn that besides the case in which  $x = 2$ , which corresponds to the equation  $x^3 = 8$ , there are also two other values of  $x$  whose cubes are also 8. These are — I.  $x = -1 + \sqrt{-3}$ ; and, II.  $x = -1 - \sqrt{-3}$ ; which will be evident from cubing them. Thus —

$\begin{array}{r} -1 + \sqrt{-3} \\ -1 + \sqrt{-3} \\ \hline 1 - \sqrt{-3} \\ -\sqrt{-3} - 3 \\ \hline -2 - 2\sqrt{-3} \text{ square} \\ -1 + \sqrt{-3} \\ \hline 2 + 2\sqrt{-3} \\ -2\sqrt{-3} + 6 \\ \hline 8 \text{ cube} \end{array}$	$\begin{array}{r} -1 - \sqrt{-3} \\ -1 - \sqrt{-3} \\ \hline 1 + \sqrt{-3} \\ + \sqrt{-3} - 3 \\ \hline -2 + 2\sqrt{-3} \\ -1 - \sqrt{-3} \\ \hline 2 - 2\sqrt{-3} \\ + 2\sqrt{-3} + 6 \\ \hline 8 \text{ cube} \end{array}$
---	--

These values, it is true, are imaginary or impossible, yet they must not be neglected; and, indeed, what has been said applies to every cubic equation, such as  $x^3 = a$ ; namely, that besides the value  $x = \sqrt[3]{a}$  we shall always find two other values. To abridge the calcu-

lation, let us suppose  $\sqrt{a}=c$ , so that  $a=c^3$ ; the equation will then assume this form,  $x^3-c^3=0$ , which will be divisible by  $x-c$ , as under.

$$\begin{array}{r} x-c) x^3-c^3 (xx+cx+cc \\ \underline{x^3-cxx} \\ \phantom{x-c)} cx-c^3 \\ \underline{cx-c^3} \\ \phantom{x-c)} 0 \end{array}$$

Consequently the equation in question may be represented by the product  $(x-c) \times (xx+cx+cc)=0$ , which, in fact,  $\text{is } =0$ , not only when  $x-c=0$ , or  $x=c$ , but also when  $xx+cx+cc=0$ . This expression contains two values of  $x$ , inasmuch as it gives  $xx=-cx-cc$ , and  $x=-\frac{c}{2} \pm \sqrt{\frac{cc}{4}-cc}$ , or  $x=\frac{-c \pm \sqrt{-3cc}}{2}$ , that is,  $x=\frac{-c \pm \sqrt{-3}}{2} = \frac{-1 \pm \sqrt{-3}}{2} \times c$ . Now,  $c$  having been substituted for  $\sqrt[3]{a}$ , we conclude that every equation of the third degree of the form  $x^3=a$  furnishes three values of  $x$ , expressed thus:—

$$\text{I. } x = \sqrt[3]{a}. \quad \text{II. } x = \frac{-1+\sqrt{-3}}{2} \times \sqrt[3]{a}. \quad \text{III. } x = \frac{-1-\sqrt{-3}}{2} \times \sqrt[3]{a}.$$

This shows that every cube root has three different values, but that one only is real, and the other two impossible: and this is the more remarkable, since every square root has two values; and if we were to pursue the subject, (which is not our intention, since the subject is unnecessary for the architect, but if he wishes he must refer to books on the subject,) we should find that every biquadratic root has four different values, and so on with fifth roots, &c. In ordinary calculations only the first of those values is employed, the other two being imaginary. We subjoin some examples:—

I. To find a number whose square multiplied by its fourth part shall produce 432.

Let the number  $=x$ ; then the product of  $xx$  multiplied by  $\frac{1}{4}x$  must  $= 432$ : that is,  $\frac{1}{4}x^3=432$ , and  $x^3=1728$ .

By extracting the cube root we have  $x=12$ . The number sought, then, is 12 for its square multiplied by its fourth part, or by  $3=432$ .

II. To find a number whose fourth power divided by its half, with  $14\frac{1}{4}$  added to the product, is 100.

Let the number  $=x$ ; its fourth power will be  $x^4$ .

Dividing by the half, or  $\frac{1}{2}x$ , we have  $2x^3$ ; and adding to that  $14\frac{1}{4}$ , the sum must be 100.

We have, therefore,  $2x^3+14\frac{1}{4}=100$ ; subtracting  $14\frac{1}{4}$  the remainder is  $2x^3=\frac{313}{4}$ .

Dividing by 2 we have  $x^3=\frac{313}{8}$ , and extracting the cube root we find  $x=\sqrt[3]{\frac{313}{8}}$ .

#### RESOLUTION OF COMPLETE EQUATIONS OF THE THIRD DEGREE.

849. An equation of the third degree is said to be *complete* when besides the cube of the unknown quantity it contains the unknown quantity itself and its square; so that the general formula for these equations, bringing all the terms to one side, is,

$$ax^3 \pm bx^2 \pm cx \pm d = 0.$$

850. We here propose to show the method of deriving from such equations the values of  $x$ , which are also called the *roots* of the equation. There is no doubt, as we have seen in the last section, that such an equation has three roots, as in respect of pure equations of the same degree.

851. First, then, considering the equation  $x^3-6xx+11x-6=0$ ; since an equation of the second degree may be considered as the product of two factors, an equation of the third degree may be represented by the product of three factors, which in the present instance are  $(x-1) \times (x-2) \times (x-3)=0$ ; for by actually multiplying them we obtain the given equation. Thus,  $(x-1) \times (x-2)$  gives  $xx-3x+2$ , and this multiplied by  $(x-3)$  gives  $x^3-6xx+11x-6$ , which are given quantities, and  $=0$ . This happens when the product  $(x-1) \times (x-2) \times (x-3)$  becomes nothing; and as it is sufficient for this purpose that one of the factors  $=0$ , three different cases may give this result; namely, when  $x-1=0$ , or  $x=1$ ; secondly, when  $x-2=0$ , or,  $x=2$ ; and lastly, when  $x-3=0$ , or,  $x=3$ . If any number whatever besides one of the above three were substituted for  $x$  none of the factors would become  $=0$ , and consequently the product would no longer  $=0$ , which proves that the equation can have no other root than those three. If in every other case three factors of such an equation could be assigned in the same manner, we should immediately have three roots. Let us, then, consider more generally these three factors,  $x-p$ ,  $x-q$ ,  $x-r$ . Seeking their product, the first multiplied by the second gives  $xx-(p+q)x+pq$ , and this

product multiplied by  $x-r$  makes  $x^3-(p+q+r)xx+(pq+pr+qr)x-pqr$ . If this formula must become  $=0$ , it may happen in three cases: first, when  $x-p=0$  or  $x=p$ ; second, when  $x-q=0$ , or  $x=q$ ; third, when  $x-r=0$ , or  $x=r$ . Let us then represent the quantity found by the equation  $x^3-axx+bx-c=0$ . That its three roots may be, I.  $x=p$ ; II.  $x=q$ ; III.  $x=r$ , it is evident we must have, 1st.  $a=p+q+r$ ; 2d.  $b=pq+pr+qr$ ; and 3d.  $c=pqr$ ; from which we find that the second term contains the sum of the three roots; that the third term contains the sum of the products of the roots taken two by two; and lastly, that the fourth term consists of the product of all the three roots multiplied together. From this last property is deduced the truth, that an equation of the third degree can have no other rational roots than the divisors of the last term, for that term being the product of the three roots must be divisible by each of them. Hence, to find a root by trial, we immediately see what numbers we are to choose.

852. Let us, for instance, consider the equation  $x^3=x+6$ , or  $x^3-x-6=0$ . As this equation can have no other rational roots but numbers which are factors of the last term 6, we have only the numbers 1, 2, 3, 6 to try with, the result whereof will be as follows:—

- I. If  $x=1$ , we have  $1-1-6=-6$ .
- II. If  $x=2$ , we have  $8-2-6=0$ .
- III. If  $x=3$ , we have  $27-3-6=18$ .
- IV. If  $x=6$ , we have  $216-6-6=204$ .

From which we see that  $x=2$  is one of the roots of the given equation; and it will now be easy to find the other two; for  $x=2$  being one of the roots,  $x-2$  is a factor of the equation, and the other factor is to be sought by means of division, as follows:—

$$\begin{array}{r}
 x-2 \overline{) x^3 - x - 6} \\
 \underline{x^3 - 2x^2} \phantom{+ 3x} \\
 2x^2 - x - 6 \\
 \underline{2x^2 - 4x} \phantom{- 6} \\
 3x - 6 \\
 \underline{3x - 6} \\
 0
 \end{array}$$

853. Since, then, the formula is represented by the product  $(x-2) \times (xx+2x+3)$ , it will become  $=0$  as well when  $x-2=0$  as when  $xx+2x+3=0$ . This last factor gives  $xx=-2x-3$ ; and consequently  $x=-1 \pm \sqrt{-2}$ . These are the other two roots of the equation, and they are evidently impossible or imaginary.

854. The operation explained is, however, only applicable when the first term  $x^3$  is multiplied by 1, the other terms of the equation having integer coefficients. When this is not the case, a mode must be adopted by which the equation is transformed into another having the condition required, after which the trial mentioned may be made.

855. Let us, for instance, take the equation  $x^3-3xx+\frac{11}{4}x-\frac{3}{8}=0$ . As there are four parts in it, let us make  $x=\frac{y}{2}$ ; we shall then have  $\frac{y^3}{8}-\frac{3yy}{4}+\frac{11y}{8}-\frac{3}{8}=0$ , and multiplying by 8 we obtain the equation  $y^3-6yy+11y-6=0$ ; the roots of which are, as we have already seen,  $y=1$ ,  $y=2$ ,  $y=3$ ; whence in the given equation we have, I.  $x=\frac{1}{2}$ ; II.  $x=1$ ; III.  $x=\frac{3}{2}$ .

Let us take an equation in which the coefficient of the first term is a whole number, different from 1, and whose last term is 1: for instance,  $6x^3-11xx+6x-1=0$ . Dividing by 6 we have  $x^3-\frac{11}{6}xx+x-\frac{1}{6}=0$ . The equation may be cleared of fractions by the method just shown. First, supposing  $x=\frac{y}{6}$ , we shall have  $\frac{y^3}{216}-\frac{11yy}{216}+\frac{y}{6}-\frac{1}{6}=0$ ; and multiplying by 216 the equation becomes  $y^3-11yy+36y-36=0$ . It would be tedious to try all the divisors of the number 36, and as the last term of the original equation is 1, it is better, in this equation, to suppose  $x=\frac{1}{z}$ , for we shall then have  $\frac{6}{z^3}-\frac{11}{z^2}+\frac{6}{z}-1=0$ . Transposing the terms  $z^3-6zz+11z-6=0$ , the roots are here  $z=1$ ,  $z=2$ ,  $z=3$ , whence in our equation  $x=1$ ,  $x=\frac{1}{2}$ ,  $x=\frac{1}{3}$ .

856. It has been heretofore shown that to have all the roots in positive numbers the signs *plus* and *minus* must succeed each other alternately; by this means, the equation takes the form  $a^3-axx+bx-c=0$ ; the signs changing as many times as there are positive roots. Had the three roots been negative, and the three factors  $x+p$ ,  $x+q$ ,  $x+r$  had been multiplied together, all the terms would have had the sign *plus*, and the form of the equation would have been  $x^3+axx+bx+c=0$ , wherein the same signs follow each other three times, that is, the number of the negative roots.

857. From this we may learn that as often as the signs change the equation has positive roots, and when the same signs follow each other the equation has negative roots; and this teaches us whether the divisors of the last term are to be taken affirmatively or negatively, when we wish to make the trial that has been mentioned.

In order to illustrate this, take the equation  $x^3 + x^2 - 34x + 56 = 0$ , wherein the signs change twice and the same sign occurs only once. We see thus that the equation has two positive roots and one negative root; and as the roots must be divisors of the last term 56, they must be included in the numbers  $\pm 1, 2, 4, 7, 8, 14, 28, 56$ .

858. Let us, then, make  $x = 2$ , and then  $8 + 4 - 68 + 56 = 0$ ; whence it would appear that  $x = 2$  is a positive root, and therefore that  $x - 2$  is a divisor of the equation whereby the other two roots may easily be found; for, dividing by  $x - 2$ , we have

$$\begin{array}{r}
 (x-2)x^3 + x^2 - 34x + 56 \div (x-2) \\
 \underline{x^3 - 2x^2} \phantom{+ 56} \\
 3x^2 + x^2 - 34x + 56 \\
 \underline{3x^2 - 6x} \phantom{+ 56} \\
 -28x + 56 \\
 \underline{-28x + 56} \\
 0
 \end{array}$$

Making this quotient  $x^2 + 3x - 28 = 0$ , we find the other two roots, which will be  $x = -\frac{3}{2} \pm \sqrt{\frac{9}{4} + 28} = -\frac{3}{2} \pm \frac{11}{2}$ , that is,  $x = 4$  or  $x = -7$ ; and considering the root beforehand,  $x = 2$ , we perceive that the equation has two positive roots and one negative. We subjoin some examples.

(I.) What numbers are those whose difference is 12, and whose product multiplied by their sum makes 14560?

Let the less of the two numbers  $= x$ . The greater will be  $x + 12$ .

Their product  $= x(x + 12)$ , multiplied by the sum  $2x + 12$ , gives  $2x^3 + 36x^2 + 144x = 14560$ .

Divide by 2, and we have  $x^3 + 18x^2 + 72x = 7280$ .

The last term 7280 is too great to make trial of all the divisors, and it is divisible by 8, wherefore we shall make  $x = 2y$ ; because the new equation  $8y^3 + 72y^2 + 144y = 7280$ , after the substitution, being divided by 8, becomes  $y^3 + 9y^2 + 18y = 910$ .

To solve this, we only need try the divisors 1, 2, 5, 7, 10, 13, &c. of the number 910. Now it is evident that the first three are too small. Begin, therefore, by supposing  $y = 7$ , and we find it is one of the roots, for the substitution gives  $343 + 441 + 126 = 910$ . It follows, then, that  $x = 14$ , and the other roots are found by dividing  $y^3 + 9y^2 + 18y - 910$  by  $y - 7$ , as follows:—

$$\begin{array}{r}
 (y-7)y^3 + 9y^2 + 18y - 910 \div (y-7) \\
 \underline{y^3 - 7y^2} \phantom{+ 18y - 910} \\
 16y^2 + 18y - 910 \\
 \underline{16y^2 - 112y} \phantom{- 910} \\
 130y - 910 \\
 \underline{130y - 910} \\
 0
 \end{array}$$

Supposing this quotient  $yy + 16y + 130 = 0$ , we have  $yy = -16y - 130$ , and thence  $y = -8 \pm \sqrt{-66}$ , which proves that the other two roots are impossible. The numbers sought, therefore, are 14 and 26, the product of which, 364, multiplied by their sum, 40, gives 14560.

(II.) What numbers are those whose difference may be 18, and their sum multiplied by the difference of their cubes may produce the number 275184?

Let the lesser number  $= x$ . Then the greater will be  $x + 18$ .

The cube of the first will be  $= x^3$ , and the cube of the second  $= (x + 18)^3 = x^3 + 54x^2 + 972x + 5832$ .

The difference of the cubes  $= 54x^2 + 972x + 5832 = 54(x^2 + 18x + 108)$  multiplied by the sum  $2x + 18$ , or  $2(x + 9)$ , gives the product  $108(x^3 + 27x^2 + 270x + 972) = 275184$ . Dividing by 108, we have  $x^3 + 27x^2 + 270x + 972 = 2548$ , or  $x^3 + 27x^2 + 270x = 1576$ .

The divisors of 1576 are 1, 2, 4, 8, &c. Let us try  $x = 4$ , and we shall find it will satisfy the terms of the equation.

It remains then to divide by  $x - 4$  to find the other two roots. The quotient will be found to be  $x^2 + 31x + 394$ ; making, therefore,  $xx = -31x - 394$ , we find  $x = -\frac{31}{2} \pm$

$$\sqrt{\frac{961}{4} - \frac{1576}{4}}, \text{ that is, two imaginary roots.}$$

The numbers sought, therefore, are 4 and 22.

(III.) What numbers are those whose difference is 12, and the product of this difference by the sum of their cubes is 102144?

Let the lesser number  $= x$ ; the greater will be  $x + 12$ .

The cube of the first is  $= x^3$ ; the cube of the second is  $x^3 + 36x^2 + 432x + 1728$ .

The product of the sum of these cubes by the difference 12, is  $12(2x^3 + 36xx + 432x + 1728) = 102144$ .

Dividing by 12 and 2, we have  $x^3 + 18xx + 216x + 864 = 4256$ , or  $x^3 + 18xx + 216x = 3392 = 8 \times 8 \times 53$ .

Suppose  $x = 2y$ , and substituting and dividing by 8, we have  $y^3 + 9yy + 54y = 8 \times 53 = 424$ .

The divisors of 424 are 1, 2, 4, 8, 53, &c. 1 and 2 are too small; but making  $y = 4$  we find  $64 + 144 + 216 = 424$ ; so that  $y = 4$  and  $x = 8$ , whence we conclude that the two numbers sought are 8 and 20.

859. We shall here close our brief explanation of the principal rules of algebra: they are to be considered more in the light of a preparation for reading and understanding the analytical reasoning and formulæ that we shall hereafter have to use, than as intended to perfect the architectural student in that whereof they treat. He that desires a more intimate acquaintance with the analytical process will of course apply himself to works expressly on the subject. Nevertheless our work could not have been considered complete without that which we have supplied.

860. It remains for us to give, under this chapter, a few applications of the use of decimals, whose nature has already been explained, and to close it with an explanation of duodecimals and the mode of working; to which we now proceed.

#### DECIMALS.

861. In subsect. 783. *et seq.* the mode of converting vulgar into decimal fractions has been explained. We shall here more particularly apply them to the general subject of our work. Great facilities arise from their application, though there be many fractions of common occurrence which cannot be expressed in decimals without a great number of figures. The following table will show the mode of expressing in decimals the fractional parts of a foot, and will further illustrate the mode of writing down numbers in decimals:—

Feet.	Inches.		
1	1	in vulgar fractions	$1\frac{1}{12}$ , in decimal fractions
5	2		$5\frac{1}{6}$ . . . . . 5·166666
4	3		$4\frac{1}{4}$ . . . . . 4·25
0	4		$\frac{1}{3}$ . . . . . 0·333333
3	5		$3\frac{5}{12}$ . . . . . 3·416666
23	6		$23\frac{1}{2}$ . . . . . 23·5
548	7		$548\frac{7}{12}$ . . . . . 548·583333

We may here repeat, that the value of a decimal fraction is not altered by any ciphers on its right hand; thus, ·2500 is of the same value as ·25, but every cipher added between the number and the decimal point decreases the value of the decimal ten times: thus  $\cdot 25 = \frac{1}{4}$ ;  $\cdot 025 = \frac{1}{40}$ ; and  $\cdot 0025 = \frac{1}{400}$ . The mode of finding the value of recurring decimals has already been given (subsect. 793.); we shall, therefore, proceed to the reduction of a decimal to its corresponding value in inferior denominations. For effecting this, the decimal must be multiplied by the number of parts its integer contains of the denomination to which it is to be reduced, and point off to the left as many figures in the product as there are places in the decimal.

862. Thus, to find the inches and parts equivalent to ·5417 of a foot. Remembering that a foot contains 12 inches, we have—

$$\begin{array}{r} \cdot 5417 \\ 12 \\ \hline 6 \cdot 5004 \text{ inches; and 1 inch consisting of} \\ 12 \text{ parts} \end{array}$$

6·0048 parts; hence ·5417 is equal to 6 inches, and 6·0048 parts.

Again, to find the value in shillings and pence of ·525 of a pound sterling, we have—

$$\begin{array}{r} \cdot 525 \\ 20 \text{ shillings in a pound} \\ \hline 10 \cdot 500 \\ 12 \\ \hline 6 \cdot 000 \end{array}$$

6·000; that is, 10 shillings and 6 pence.

Reciprocally, to find what decimal of a foot are 6 inches 6·0048, we have, first, —

$$\begin{array}{r} \text{Parts in an inch, } 12) 6 \cdot 0048 \\ \hline \text{Parts in a foot, } 12) 6 \cdot 5004 \end{array}$$

·5417, the decimal required.

Again, to find what decimal of a pound sterling are ten shillings and sixpence : here we have —

Pence in a shilling 12) 6·0

Shillings in a pound 20)10·5

·525, the decimal required.

863. The *addition* of decimal fractions is performed by placing the different numbers with the points directly under each other, and then the addition is made as in whole numbers, observing to place the point in the sum under its place in the numbers.

Example. — Add the numbers 3·5675, 21·375, and 760·00875 together.

$$\begin{array}{r} 3\cdot5675 \\ 21\cdot375 \\ 760\cdot00875 \\ \hline 784\cdot95125 \end{array}$$

864. The *subtraction* of decimal fractions is performed by placing the fractions with the points directly under each other, and subtracting as in whole numbers.

Example. — From 98·735 take 12·96785.

$$\begin{array}{r} 98\cdot735 \\ 12\cdot96785 \\ \hline 85\cdot76715 \end{array}$$

865. The *multiplication* of decimal fractions is performed as in integers, taking care to place the decimal point in the product to the left of as many decimals as are contained in both factors. But if there be not as many places in the product as are contained in both factors, ciphers must be placed to the left to make up the deficiency.

Example. — Multiply 7·335 by 7·5.

$$\begin{array}{r} 7\cdot335 \\ 7\cdot5 \\ \hline 36675 \\ 51345 \\ \hline 55\cdot0125 \end{array}$$

In this case there are three decimal places in the multiplicand, and one in the multiplier. Four decimals must therefore be cut off from the right.

Example. — Multiply ·07325 by ·5235.

$$\begin{array}{r} \cdot07325 \\ \cdot5235 \\ \hline 36625 \\ 21975 \\ 14650 \\ 36625 \\ \hline \cdot038346375 \end{array}$$

Here, because there are five places of decimals in the multiplicand and four in the multiplier, making, in all, nine places, and only eight places come from the multiplication, we must prefix a cipher to make up the nine places.

866. The *division* of decimal fractions is performed as in whole numbers, pointing off from the right of the quotient as many figures for decimals as the dividend has more decimal places than the divisor. If the quotient have not so many figures as the decimals in the dividend exceed those in the divisor, ciphers must be prefixed to the left to make up the deficiency before the point be placed.

Example. — Divide 7·375 by 5·25.

$$\begin{array}{r} 5\cdot25)7\cdot3750000(1\cdot40476 \\ 5\ 25 \\ \hline 2\ 125 \\ 2\ 100 \\ \hline 2500 \\ 2100 \\ \hline 4000 \\ 3675 \\ \hline 3250 \\ 3150 \\ \hline 100 \end{array}$$

Now the dividend with the ciphers annexed has seven places of decimals, and the divisor only two; we must therefore cut off five places from the right hand for the decimals of the quotient.

Example. — Divide .5675 by 72.5.

$$\begin{array}{r}
 72.5 \overline{) .5675000} \quad (.007827 \\
 \underline{5075} \phantom{000} \\
 6000 \phantom{00} \\
 \underline{5800} \phantom{00} \\
 2000 \phantom{00} \\
 \underline{1450} \phantom{00} \\
 5500 \phantom{00} \\
 \underline{5075} \phantom{00} \\
 425
 \end{array}$$

867. The dividend has, with the ciphers that have been annexed, seven places of decimals, and the divisor only one place; hence we cut off from the right six places for the decimal of the quotient. But on examination it is found that there are only four significant figures obtained; two ciphers must, therefore, be prefixed to the quotient.

#### DUODECIMALS.

868. Duodecimals are a series of denominations beginning with feet, wherein every inch in the lower denomination makes twelve in that next above it, and they form a series of fractions, whereof the denominations are understood, but not expressed. This method is chiefly in use among measurers of artificers' works, for computing the contents of work. The dimensions are taken in feet, inches, and twelfths of an inch, but not nearer, except in works of the greatest nicety. Feet and inches are marked with their initial letters, but twelfths or seconds by a double accent, thus 2'', and thirds by a triple accent, thus 5'''.

869. To multiply duodecimals together, write down the two dimensions so to be multiplied in such way that the place of feet may stand under the last place of the multiplicand; begin with the right hand denomination of the multiplier, and multiply it by every denomination of the multiplicand, throwing the twelve out of every product, and carrying as many units as there are twelves to the next. Placing the remainders, if any, under the multiplier, so that the like parts in the product may be under like parts of the multiplicand, proceed with every successive figure of the multiplier towards the left, in the same manner, always placing the first figure of the product under the multiplier. Then the sum of these partial products will be the whole product. In duodecimals there will be as many denominations below feet as in both the factors taken together.

Example 1. — Multiply 7 ft. 5 in. by 3 ft. 4 in.

$$\begin{array}{r}
 7 : 5 \\
 3 : 4 \\
 \hline
 2 : 5 : 8 \\
 22 : 3 \\
 \hline
 24 : 8 : 8 \\
 14 : 5 : 0 : 8 \\
 74 : 2 : 0 \\
 \hline
 88 : 7 : 0 : 8
 \end{array}$$

Example 2. — Multiply 24 ft. 8 in. 8'' by 3 ft. 7 in.

$$\begin{array}{r}
 24 : 8 : 8 \\
 3 : 7 \\
 \hline
 14 : 5 : 0 : 8 \\
 74 : 2 : 0 \\
 \hline
 88 : 7 : 0 : 8
 \end{array}$$

870. In the first example there is only one place of duodecimals in each factor; there are therefore two places in the product. In the second example there are two places of duodecimals in the multiplicand and one in the multiplier, which make, together, three; there are therefore three denominations in the product. This method of placing the denominations of the factors gives the correct places of the product at once; since like parts of the product stand under like parts of the multiplicand. It also shows the affinity between duodecimals, decimals, and every series or scale of denominations whereof any number divided by the radix of the scale makes one of the next towards the left hand. The consideration is, moreover, useful in discovering readily the kind of product arising from the multiplication of any two single denominations together.

871. When the number of feet runs very high in the factors, it will be much better to write down the product of each multiplication, without casting out the twelve, and add

together those of each denomination beginning on the right, and divide by 12, to carry to the next higher place, then add these, and so on, as often as there are places in the whole product.

Example. — Multiply 262 ft. 5 in. by 54 ft. 8 in.

$$\begin{array}{r}
 262 : 5 \\
 54 : 8 \\
 \hline
 1048 : 20 \\
 13100 : 250 \\
 \hline
 197 = \frac{2369}{12} \\
 \hline
 14345 : 5 : 4
 \end{array}$$

Thus, under inches, the products being set down and added, they amount to 2369, which, divided by twelve, gives 197 to carry to the place of feet, and 5 remainder. Then adding the feet together with the quantity carried, it gives the whole number of feet; while the operation is extremely simple and free from the troubles of either side operations or useless stress on the memory.

872. The division of the foot into 12 parts renders the application of the rules of *practice* very valuable in the computation of duodecimals. The practical rule is to set down the two dimensions one under the other, that is, feet under feet and inches under inches, and multiply each term in the multiplicand by the feet in the multiplier, beginning at the lowest; and, if the numbers be large, put down the inches without carrying 1 for every 12 from inches to feet. Then, instead of multiplying by the inches, take such aliquot parts of the multiplicand as the inches are of a foot; after which add the lines together, carrying 1 for every 12 inches.

Example 1. — Multiply 7 ft. 5 in. by 3 ft. 4 in.

$$\begin{array}{r}
 4 \text{ in.} = \frac{1}{3} \\
 7 : 5 \\
 3 : 4 \\
 \hline
 22 : 3 \\
 2 : 5 : 8 \\
 \hline
 24 : 8 : 8
 \end{array}$$

Example 2. — Multiply 262 ft. 5 in. by 54 ft. 8 in.

$$\begin{array}{r}
 8 = \frac{2}{3} \\
 262 : 5 \\
 54 : 8 \\
 \hline
 1048 : 270 \\
 1310 \\
 87 : 5 : 8 \\
 87 : 5 : 8 \\
 \hline
 23 = \frac{281}{12} : 4 \\
 \hline
 14345 : 5 : 4
 \end{array}$$

The same examples have been used to show the relative advantage of the two methods.

873. The abridgment of the labours of practical men is always a matter of importance — being identical with the saving of time which is lost in calculation, and which with the architect is of the utmost importance, when it is recollected what multifarious duties he has to discharge. Hence we doubt not that the following table of squares, cubes, and roots of numbers, up to 1000, will be most acceptable to him. An inspection of the table will at once instruct him in the method of using it. The first column shows the number, the second the square of such number, the third exhibits its cube. In the fourth column is found the square root of the number, and in the fifth its cube root.

Thus, looking to the number 61 in the first column, we find its square to be 3721, its cube 226981, its square root 7·8102497, and its cube root 3·936497.

Again, taking the number 784, we find its square to be 613089, its cube 481890304, its square root 28, and its cube root 9·220872. We presume that we need not further enlarge on instructions on its use.

## SECT. II.

## GEOMETRY.

874. Geometry is that science which treats of the relations and properties of the boundaries of either body or space. The invention of the science has been referred to a very remote period: by some, to the Babylonians and Chaldeans; by others, to the Egyptians, who are said to have used it for determining the boundaries of their several lands, after the inundations of the Nile. Cassiodorus says that the Egyptians either derived the art from the Babylonians, or invented it after it was known to them. It is supposed that Thales, who died 548 a. c., and Pythagoras of Samos, who flourished about 520 a. c., introduced it from Egypt into Greece. We do not, however, consider it useful here to enter into the history of the science; neither is it necessary to enter into the reasons which have induced us to adopt the system of Rossignol, from whom we extract this section, otherwise than to state that we hope to conduct the student by a simpler and more intelligible method to those results with which he must be acquainted.

The limits of body or space are surfaces, and the boundaries of surfaces are lines, and the terminations of lines are points. Bounded spaces are usually called solids, whether occupied by body or not; the subject, therefore, is naturally divided into three parts, — lines, surfaces, and solids; and these have two varieties, dependent on their being straight or curved.

875. Geometrical inquiry is conducted in the form of propositions, problems, and demonstrations, being always the result of comparing equal parts or measures. Now, the parts compared may be either lines or angles, or both; hence, the nature of each method should be separately considered, and then the united power of both employed to facilitate the demonstration of propositions. But the reader must first understand the following

## DEFINITIONS.

1. A solid is that which has length, breadth, and thickness. A slab of marble, for instance, is a solid, since it is long, broad, and thick.
2. A surface is that which has length and breadth, without thickness. A leaf of paper, though not in strictness, inasmuch as it has thickness, may convey the idea of a surface.
3. A line is that which has length, but neither breadth nor thickness. As in the case of a surface, it is difficult to convey the strict notion of a line, yet an infinitely thin line, as a hair, may convey the idea of a line: a thread drawn tight, a straight line.
4. A point is that which has neither length, breadth, nor thickness. A very fine grain of sand may give an idea of it.
5. If a line be carried about a point A, so that its other extremity passes from B to C, from C to D, &c. (*fig. 223.*), the point B, in its revolution, will describe a curve BCDFLB. This curve line is called the *circumference* of a circle. The circle is the space enclosed by this circumference. The point A, which, in the formation of the circle is at rest, is called the *centre*. The right lines AC, AD, AF, &c. drawn from the centre to the circumference, are called *radii*. A *diameter* is a right line which passes through the centre, and is terminated both ways by the circumference. The line DAL, for example, is a diameter. An *arc* is a part of a circumference, as FG.
6. The circumference of a circle is divided into 360 equal parts, called *degrees*; each degree is divided into 60 parts, called *minutes*, and each minute into 60 parts, called *seconds*. Every circle, without relation to its magnitude, is supposed to be equally divided into degrees, minutes, and seconds.
7. Two right lines drawn from the same point, and diverging from each other, form an opening which is called an *angle*. An angle is commonly expressed by three letters, and it is usual to place in the middle that letter which marks the point whence the lines diverge; thus, we say the angle BAC or DAF (*fig. 224.*), and not the angle ABC or ACB.
8. The magnitude of an angle does not depend on the lines by which it is formed, but upon their distance from each other. How far soever the lines AB, AC are continued, the angle remains the same. One angle is greater than another when the lines of equal length by which it is formed are more distant. Thus the angle BAL (*fig. 223.*) is greater than the angle CAB, because the lines AB, AL are more distant from each other or include a greater arc than the lines AC, AB. If the legs of a pair of compasses be a little separated, an angle is formed; if they be opened wider, the angle becomes greater; if they be brought nearer, the angle becomes less.

Fig. 223.

Fig. 224.

Fig. 225.

9. If the point of a pair of compasses be applied to the point G (*fig. 225.*), and a circumference NRB be described, the arc NR contained within the two lines GL, GM will measure the magnitude of the angle LGM. If the arc NR, for example, be an arc of 40 degrees, the angle LGM is an angle of 40 degrees.
10. There are three kinds of angles (*fig. 226.*): a *right angle* (I), which is an angle of 90 degrees; an *obtuse angle* (II), which contains more than 90 degrees; and an *acute angle* (III), which contains less than 90 degrees.
11. One line is *perpendicular* to another when the two angles it makes with that other line are equal: thus, the line CD (*fig. 227.*) is perpendicular to the line AB, if the angles CDA, CDB contain an equal number of degrees.
12. Two lines are *parallel* when all perpendiculars drawn from one to the other are equal; thus, the lines FG, AB (*fig. 228.*) are parallel, if all the perpendiculars *cd*, *cd*, &c. are equal.
13. A *triangle* is a surface enclosed by three right lines, called *sides* (*fig. 229.*). An *equilateral triangle* (I) is that which has three sides equal; an *isosceles triangle* has only two of its sides equal (II); a *scalene triangle* (III) has its three sides unequal.
14. A *quadrilateral figure* is a surface enclosed by four right lines, which are called its sides.
15. A *parallelogram* is a quadrilateral figure, which has its opposite sides parallel; thus,

Fig. 226.

Fig. 227.

Fig. 228.

Fig. 229.

Fig. 230.

if the side BC (*fig. 230.*) is parallel to the side AD, and the side AB to the side DC, the quadrilateral figure ABCD is called a parallelogram.

16. A *rectangle* is a quadrilateral figure all the angles whereof are right angles, as ABCD (*fig. 231.*).
17. A *square* is a quadrilateral figure whose sides are all equal and its angles right angles (*fig. 232.*).
18. A *trapezium* is any quadrilateral figure not a parallelogram.
19. Those figures are *equal* which enclose an equal space; thus, a circle and a triangle are equal, if the space included within the circumference of the circle be equal to that contained in the triangle.
20. Those figures are *identical* which are equal in all their parts; that is, which have all their angles equal and their sides equal, and enclose equal spaces, as BAC, EDG (*fig. 233.*). It is manifest that two figures are identical which, being placed one upon the other, perfectly coincide, for in that case they must be equal in all their parts. It must be observed, that a line merely so expressed always denotes a right line.

Fig. 231.

Fig. 232.

Fig. 233.

**AXIOM.** Two right lines cannot enclose a space; that category requires at least three lines.

#### RIGHT LINES AND RECTILINEAL FIGURES.

876. **PROPOSITION I.** *The radii of the same circle are all equal.*

The revolution of the line AB about the point A (*fig. 234.*) being necessary (Defn. 5.) to form the circle BCDFGLB, when in revolving the point B is upon the point C, the whole line AB must be upon the line AC; otherwise two right lines would enclose a space, which is impossible: wherefore the radius AC is equal to the radius AB. In like manner it may be proved that the radii AB, AF, AG, &c. are all equal to AB, and are therefore equal among themselves.

877. **PROP. II.** *On a given line to describe an equilateral triangle.*

Fig. 234.

Let AB (*fig. 235.*) be the given line upon which it is required to describe a triangle whose three sides shall be equal.

From the point A, with the radius AB, describe the circumference BCD, and from the point B, with the radius BA, describe the circumference ACF; and from the point C, where these two circumferences cut each other, draw the two right lines CA, CB. Then ACB is an equilateral triangle.

For the line AC is equal to the line AB, because these two lines are radii of the same circle BCD; and the line BC is equal to the line AB, because these two lines (Prop. 1.) are radii of the same circle ACF. Wherefore the lines AC and BC, being each equal to the line AB, are equal to one another, and all the three sides of the triangle ACB are equal; that is, the triangle is equilateral.

878. PROP. III. *Triangles which have two sides and the angle subtended or contained by them equal are identical.*

In the two triangles BAC, FDG (*fig. 236.*), if the side DF be equal to the side AB, and the side DG equal to the side AC, and also the angle at D equal to the angle at A, the two triangles are identical.

Suppose the triangle FDG placed upon the triangle BAC in such manner that the side DF fall exactly upon the side equal to it, AB. Since the angle D is equal to the angle A, the side DG must fall upon the side equal to it, AC; also the point F will be found upon the point B, and the point G upon the point C; consequently the line FG must fall wholly upon the line BC, otherwise two right lines would enclose a space, which is impossible. Wherefore the three sides of the triangle FDG coincide in all points with the three sides of the triangle BAC, and the two triangles have their sides and angles equal, and enclose an equal space; that is (Defin. 20.), they are identical.

879. PROP. IV. *In an isosceles triangle the angles at the base are equal.*

Let the triangle BAC (*fig. 237.*) have its sides AB, AC equal, the angles B and C at the base are also equal. Conceive the angle A to be bisected by the right line AD.

In the triangles BAD, DAC the sides AB, AC are, by supposition, equal; the side AD is common to the two triangles, and the angles at A are supposed equal. These two triangles, therefore, have two sides, and the angle contained by them equal. Hence, they are identical (Prop. 3), or have all their parts equal: whence the angles B and C must be equal.

880. PROP. V. *Triangles which have their three sides equal are identical.*

In the two triangles ACB, FDG (*fig. 238.*), let the side AC be equal to the side FD, the side CB equal to the side DG, and the side AB to the side FG; these two triangles are identical.

Let the two triangles be so joined that the side FG shall coincide with the side AB (*fig. 239.*), and draw the right line CD. Since in the triangle CAD the side AC is equal to the side AD,

the triangle is isosceles; whence (Defin. 13.) the angles *m* and *n* at the base are equal.

Since in the triangle CBD the side BC is equal to the side BD, the triangle is isosceles; whence (Defin. 13.) the angles *r* and *s* at the base are equal.

Because the angle *m* is equal to the angle *n*, and the angle *r* equal to the angle *s*, the whole angle C is equal to the whole angle D.

Lastly, because in the two triangles ACB, ADB the side AC is equal to the side AD and the side CB equal to the side DB, also the angle C equal to the angle D, these two triangles have two sides, and the contained angle equal, and are therefore (Prop. 3.) identical.

881. PROP. VI. *To divide a right line into two equal parts.*

Let the right line which it is required to divide into two equal parts be AB (*fig. 240.*). Upon AB draw (Prop. 2.) the equilateral triangle ADB, and on the other side of the same line

AB draw the equilateral triangle AFB, draw also the right line DF; AC is equal to CB.

In the two larger triangles DAF, DBF the sides DA, DB are equal, because they are the sides of an equilateral triangle; the sides AF, BF are equal for the same reason; and the side DF is common to the two triangles. These two triangles, then, have their sides equal, and consequently (Prop. 5.) are identical, or have all their parts equal; wherefore the two angles at D are equal.

Again, in the two smaller triangles ADC, CDB the side DA is made equal to the side DB, and the side DC is common to the two triangles; also the two angles at D are equal. Thus these two triangles have two sides and the contained angle equal; they are therefore (Prop. 3.) identical, and AC is equal to CB; that is, AB is bisected.

882. PROP. VII. *From a given point out of a right line to draw a perpendicular to that line.*

Let C (fig. 241.) be the point from which it is required to draw a perpendicular to the right line AB.

From the point C describe an arc of a circle which shall cut the line AB in two points F and G. Then bisect the line FG, and to D, the point of division, draw the line CD: this line is perpendicular to the line AB. Draw the lines CF, CG.

In the triangles FCD, DCG the sides CF, CG are equal, because (Prop. 1.) they are radii of the same circle; the sides FD, DG are equal, because FG is bisected; and the side CD is common. These two triangles, then, having the three sides equal, are identical (Prop. 5.). Whence (Defin. 20.) the angle CDA is equal to the angle CDB, and consequently (Defin. 11.) the line CD is perpendicular to the line AB.

883. PROP. VIII. *From a given point in a right line to raise a perpendicular upon that line.*

From the point C (fig. 242.), let it be required to raise a perpendicular upon the right line AB.

In AB take at pleasure CF equal to CG; upon the line FG describe an equilateral triangle FDG, and draw the line CD; this line will be perpendicular to AB.

In the triangles FDC, CDG the sides DF, DG are equal, because they are the sides of an equilateral triangle; the sides FC, CG are equal by construction; and the side DC is common. These two triangles, then, having the three sides equal, are (Prop. 5.) identical. Therefore (Defin. 20.) the angle DCA is equal to the angle DCB, and consequently (Defin. 11.) the line CD is perpendicular to the line AB.

884. PROP. IX. *The diameter of a circle divides the circumference into two equal parts.*

Let ADBLA (fig. 243.) be a circle; the diameter ACB bisects the circumference, that is, the arc ALB is equal to the arc ADB.

Conceive the circle to be divided, and the lower segment ACBLA to be placed upon the upper ACBDA; all the points of the arc ALB will fall exactly upon the arc ADB; and consequently these two arcs will be equal.

For if the point L, for instance, does not fall upon the arc ADB, it must fall either above this arc, as at G, or below it, as at F. If it fall on G, the radius CL will be greater than the radius CD; if it falls on F, the radius CL will be less than the radius CD, which is (Prop. 1.) impossible. The point L, then, must fall upon the arc ADB. In like manner it may be proved that all the other points of the arc ALB must fall upon the arc ADB: those two arcs are therefore equal.

885. PROP. X. *A right line which meets another right line forms with it two angles, which, together, are equal to two right angles.*

The line AC (fig. 244.) meeting the line DF, and forming with it the two angles ACD, ACF, these two angles are together equal to two right angles.

From the point C as a centre describe at pleasure a circumference. NGLMN.

The line NCL, being a diameter, divides the circumference (Prop. 9.) into two equal parts. The arc NGL is therefore half the circumference, which contains (Defin. 6.) 180, or twice 90 degrees. Therefore the angles ACD, ACF, which, taken together, are measured by the arc NGL, are twice 90 degrees, that is (Defin. 10.), are equal to two right angles.

886. PROP. XI. *A line drawn perpendicularly to another right line makes right angles with it.*

Fig. 241.

Fig. 242.

Fig. 243.

Fig. 244.

If the line CD (*fig. 245.*) be perpendicular to the line AB, the angle CDA is a right angle, and also the angle CDB.

For the line CD, meeting the line AB, forms with it two angles, which are together (Prop. 10.) equal to two right angles; and these two angles are equal, because CD is perpendicular to AB. Wherefore each angle is a right angle.

887. *PROF. XII. If two lines cut each other, the vertical or opposite angles are equal.*

Let the lines AB, DF (*fig. 246.*) cut each other at the point C; the angles ACD, FCB, which are called vertical or opposite angles, are equal.

From the point C, as a centre, describe at pleasure a circumference NGLMN.

Since the line NCL is a diameter, the arc NGL is (Prop. 9.) half the circumference; therefore the arcs NGL, GLM are equal. From these two arcs take away the common part GL, there will remain the arc NG equal to the arc LM. Consequently the angles ACD, FCB, which are measured by these two arcs, are also equal.

888. *PROF. XIII. If a line be perpendicular to one of two parallel lines, it is also perpendicular to the other.*

Let AB, CD (*fig. 247.*) be two parallel lines: if the line FG makes right angles with CD, it will also make right angles with AB.

Take at pleasure GC equal to GD; at the points C and D raise the perpendiculars CA, DB, and draw the lines GA, GB.

In the two triangles ACG, BDG, because the line AB is parallel to the line CD, the perpendiculars CA, DB are necessarily equal, as appears from the definition of parallel lines (Defin. 12.); the lines CG, DG are equal by construction; and the angles C and D are right angles. The two triangles ACG, BDG have then two sides and the contained angle equal, they are therefore (Prop. 3.) identical. Whence the side GA is equal to the side GB, and the angle *m* equal to the angle *n*.

Again, in the triangles AGF, FGB the side GA is equal to the side GB, as has been proved, and the side GF is common. Moreover, the angle *r* is equal to the angle *s*; for if from the two right angles FGC, FGD be taken away the equal angles *m* and *n*, there will remain the equal angles *r* and *s*. The triangles AGF, FGB have then two sides and the contained angle equal; they are therefore (Prop. 3.) identical. Wherefore the angles GFA, GFB are equal, and consequently are right angles.

889. *PROF. XIV. If one line be perpendicular to two other lines, these two lines are parallel.*

Let the line FG (*fig. 248.*) make right angles with the lines AB and CD; these two lines are parallel.

If the line AB be not parallel to the line CD, another line, as NH, may be drawn through the point F, parallel to the line CD. But this is impossible; for if the line NH were parallel to the line CD, the line FG making right angles with CD would also (Prop. 13.) make right angles with NH; which cannot be, because, by supposition, it makes right angles with AB.

890. *PROF. XV. The opposite sides of a rectangle are parallel.*

In the rectangle ABCD (*fig. 249.*) the side BC is parallel to the side AD, and the side AB parallel to the side DC. Produce each of the sides both ways.

The line AB is perpendicular to the two lines BC, AD; the two lines BC, AD are therefore (Prop. 14.) parallel. In like manner, the line AD is perpendicular to the two lines AB, DC; the two lines AB, DC are therefore (Prop. 14.) parallel.

891. *PROF. XVI. The opposite sides of a rectangle are equal.*

In the rectangle ABCD (see *fig. 249.*) the side AB is equal to the side DC, and the side BC equal to the side AD. For, since the side BC is parallel to the side AD, the perpendiculars AB, DC are (Defin. 12.) equal; and since the side AB is parallel to the side DC, the perpendiculars BC, AD are equal.

892. *PROF. XVII. A right line falling upon parallel lines makes the alternate angles equal.*

Let the line FG (*fig. 250.*) cut the parallels AB, GD; the angles AFG, FGD, which are called *alternate angles*, are equal. From the point G draw GL perpendicular to the line AB, and from the point F draw FM perpendicular to the line GD.

Since the line GL is perpendicular to AB, it is also (Prop. 13.) perpendicular to the

Fig. 245.

Fig. 246.

Fig. 247.

Fig. 248.

Fig. 249.

parallel line AB. Whence the quadrilateral figure GLFM is a rectangle, its four angles being right angles.

In the triangles GLF, FMG the sides LF, GM are equal, because they are opposite sides of the same rectangle; the sides LG, FM are equal for the same reason; and the side FG is common. The two triangles GLF, FMG have then the three sides equal, and consequently (Prop. 5.) are identical. Wherefore the angle LFG opposite to the side LG is equal to the angle FGM opposite to the side FM.

*Remark.* In identical triangles the equal angles are always opposite to equal sides, as by this proposition appears.

893. PROP. XVIII. *If one right line falling upon two others makes the alternate angles equal, these two lines are parallel.*

Let the alternate angles AFG, FGD (fig. 251.) be equal; the lines AB, GD are parallel.

If the line AB is not parallel to the line GD, another line, as NH, may be drawn through the point F parallel to GD. But this is impossible; for if the line NH were parallel to the line GD, the angle FGD would be (Prop. 17.) equal to the angles NFG, since these two angles would be alternate angles between two parallel lines; which cannot be, because, by supposition, the angle FGD is equal to the angle AFG.

894. PROP. XIX. *If one right line falls upon two parallel right lines, it makes the interior angle equal to the exterior.*

Let the line FG (fig. 252.) meet the parallel lines BA, DC, the interior angle  $r$  is equal to the exterior angle  $z$ . Produce the lines BA, DC.

The angle  $r$  (Prop. 17.) is equal to the angle  $s$ , because these are alternate angles, made by a right line falling upon two parallel lines, and the angles  $s$  and  $z$  are (Prop. 12.) equal, because they are vertical or opposite angles; therefore the angle  $r$  is equal to the angle  $z$ .

895. PROP. XX. *If one right line falling upon two other right lines makes the internal angle equal to the external, those two lines are parallel.*

Let the internal angle  $r$  (fig. 253.) be equal to the external angle  $z$ , the lines BA, DC are parallel.

The angle  $r$  is equal to the angle  $y$  by supposition, and the angle  $z$  (Prop. 12.) is equal to the angle  $s$ , because they are opposite angles. The alternate angles  $r, s$  are therefore equal, and consequently (Prop. 18.) the lines BA, DC are parallel.

896. PROP. XXI. *Through a given point to draw a line parallel to a given line.*

Let G be the point through which it is required to draw a line parallel to the given line MF.

From any point G (fig. 254.) describe, at pleasure, the arc FN; from the point F, in which the arc FN cuts the line MF, with the distance GF describe the arc GM meeting the line MF in M; then make FL equal to GM, and draw the line GL; this line is parallel to the line MF.

Draw the line GF.

The arcs GM, FL are equal by construction; therefore the alternate angles  $r, s$ , which are measured by these arcs (Defin. 9.), are equal; and consequently (Prop. 18.) the lines GL, MF are parallel.

897. PROP. XXII. *The three angles of a triangle taken together are equal to two right angles.*

In the triangle BAC (fig. 255.), the three angles B, A, C are together equal to two right angles.

Produce the side BC both ways; through the point A draw a line FG parallel to BC; and from the point A, as a centre, describe any circumference LMN.

The angle B (Prop. 17.) is equal to the angle  $x$ , because these are alternate angles made by a right line falling upon two parallel lines. For the same reason the angle C is equal to the angle  $y$ .

Because LAN is a diameter, the arc LMN is half the circumference; therefore the three angles  $x, A, y$ , which are measured by this arc, are together equal to two right angles.

Fig. 250.

Fig. 251.

Fig. 252.

Fig. 253.

Fig. 254.

Fig. 255.

But the angle  $x$  is equal to the alternate angle B, and the angle  $y$  to the alternate angle C.

Therefore, substituting B for  $x$ , and C for  $y$ , the three angles B, A, C are together equal to two right angles.

**COROLLARY.** Hence, if two angles of any triangle be known, the third is also found; since the third angle is that which the other two taken together wants of two right angles.

898. **PROP. XXIII.** *If two triangles have two angles equal, they have also the third angle equal.*

In the two triangles BAC, FDG (*fig. 256.*), if the angle B is equal to the angle F, and the angle A equal to the angle D, the angle C will also be equal to the angle G.

Since the angle C (Corol. to Prop. 22.) is that which the angles B and A together want of two right angles; and since the angle G is that which F and D together want of two right angles; the angles B and A being equal to the angles F and D, the angle C must be equal to the angle G.

899. **PROP. XXIV.** *The exterior angle of any triangle is equal to the two interior and opposite angles taken together.*

In the triangle BAC (*fig. 257.*) produce one of the sides BC; the angle ACD, which is called *exterior*, is equal to the two interior and opposite angles B and A taken together.

The line AC meeting the line BD forms with it two angles, which are together (Prop. 10.) equal to two right angles; the angle ACB is therefore that which the angle ACD wants of two right angles. But the angle ACB is (Corol. to Prop. 22.) also that which the angles B and A together want of two right angles. Wherefore the angle ACD is equal to the two angles B and A taken together.

900. **PROP. XXV.** *Triangles which have two angles and the side which lies between them equal are identical.*

In the two triangles BAC, FDG (*fig. 258.*), if the angle F is equal to the angle B, the angle G equal to the angle C, and the side FG equal to the side BC, these two triangles are identical.

Conceive the triangle FDG placed upon the triangle BAC in such a manner that the side FG shall fall exactly upon the equal side BC. Since the angle F is equal to the angle B, the side FD must fall upon the side BA; and since the angle G is equal to the angle C, the side GD must fall upon the side CA. Thus the three sides of the triangle FDG will be exactly placed upon the three sides of the triangle BAC; and consequently the two triangles (Prop. 5.) are identical.

901. **PROP. XXVI.** *If two angles of a triangle are equal, the sides opposite to those angles are also equal.*

Conceive the angle A (*fig. 259.*) to be bisected by the line AD.

In the triangles BAD, DAC the angle B is equal to the angle C by supposition, and the angles at A are also equal. These two triangles have their two angles equal; the third angle will therefore (Prop. 23.) be equal; whence the angles at D are equal. Moreover, the side AD is common to the two triangles. These two triangles, therefore, having two angles and the side which lies between them equal, are (Prop. 25.) identical. Wherefore the side AB is equal to the side AC.

902. **PROP. XXVII.** *The opposite sides of a parallelogram are equal.*

In the parallelogram ABCD (*fig. 260.*), the side AB is equal to the side DC, and the side BC equal to the side AD.

Draw the line BD, which is called the *diagonal*.

Because BC is parallel to AD, the alternate angles  $m$  and  $n$  are equal. In like manner, because AB is parallel to DC, the alternate angles  $r$  and  $s$  are equal. Also, the side BD is common to the two triangles BAD, BCD. These two triangles have then two angles and the side which lies between them equal, and are therefore (Prop. 3.) identical. Wherefore the side AB opposite to the angle  $n$  is (Prop. 26.) equal to the side DC opposite to the angle  $m$ ; and the side BC opposite to the angle  $s$  is equal to the side AD opposite to the equal angle  $r$ .

Fig. 256.

Fig. 257.

Fig. 258.

Fig. 259.

Fig. 260.

**COROLLARY.** Hence, the diagonal bisects the parallelogram; for the triangles BAD, BCD, having the three sides equal, are identical.

**903. PROP. XXVIII.** *Parallelograms which are between the same parallels, and have the same base, are equal.*

Let the two parallelograms ABCD, AFGD (*fig. 261.*), be between the same parallels BG, AM, and upon the same base AD; the space enclosed within the parallelogram ABCD is equal to the space enclosed within the parallelogram AFGD.

In the two triangles BAF, CDG the side BA of the former triangle is equal to the side CD of the latter, because they are opposite sides of the same parallelogram. For the same reason, the side FA is equal to the side GD. Moreover, BC is equal to AD, because they are opposite sides of the same parallelogram. For the same reason, AD is equal to FG. BC is therefore equal to FG. If to both these CF be added, BF will be equal to CG. Whence the two triangles BAF, CDG, having the three sides equal, are (*Prop. 5.*) identical, and consequently have equal surfaces.

If from these two equal surfaces be taken the small triangle CLF, which is common, there will remain the trapezium ABCL, equal to the trapezium LFGD. To these two trapezia add the triangle ALD, and the parallelogram ABCD will be equal to the parallelogram AFGD.

**904. PROP. XXIX.** *If a triangle and a parallelogram are upon the same base, and between the same parallels, the triangle is equal to half the parallelogram.*

Let the parallelogram ABCD (*fig. 262.*) and the triangle AFD be upon the same base AD, and between the same parallels BG, AL; the triangle AFD is half the parallelogram ABCD. Draw DG parallel to AF.

Because the parallelogram AFGD is bisected by the diagonal FD (*Prop. 27. Corol.*), the triangle AFD is half the parallelogram AFGD. But the parallelogram AFGD is equal to the parallelogram ABCD, because these two parallelograms are upon the same base, and between the same parallels; therefore the triangle AFD is equal to half the parallelogram ABCD.

**905. PROP. XXX.** *Parallelograms which are between the same parallels, and have equal bases, are equal.*

Let the two parallelograms ABCD, LFGM (*fig. 263.*) be between the same parallels BG, AM, and have the equal bases AD, LM; these two parallelograms are equal.

Draw the lines AF, DG.

Because AD is equal to LM, and LM to FG, AD is equal to FG; and they are parallel by construction. Also AF and DG are parallel; for if DG be not parallel to AF, another line may be drawn parallel to it; whence FG will become greater or less than AD. AF and AG are therefore parallel, and AFGD a parallelogram.

Now the parallelogram ABCD is (*Prop. 28.*) equal to the parallelogram AFGD, because these two parallelograms are between the same parallels, and have the same base AD. And the parallelogram AFGD is equal to the parallelogram LFGM, because these two parallelograms are between the same parallels, and have the same base FG. The parallelogram ABCD is therefore equal to the parallelogram LFGM.

**906. PROP. XXXI.** *Triangles which are between the same parallels, and have equal bases, are equal.*

Let the two triangles ABD, LFM (see *fig.* to preceding Proposition) be between the same parallels BG, AM, and upon the equal bases AD, LM; these two triangles are equal.

Draw DC parallel to AB, and MG parallel to LF.

The two parallelograms ABCD, LFGM are equal (*Prop. 30.*), because they are between the same parallels, and have equal bases. But the triangle ABD is (*Prop. 29.*) one half of the parallelogram ABCD, and the triangle LFM is one half of the parallelogram LFGM; these two triangles are therefore equal.

**907. \*PROP. XXXII.** *In a right-angled triangle, the square of the hypotenuse, or side subtending the right angle, is equal to the squares of the sides which contain the right angle.*

In the triangle BAC (*fig. 264.*), let the angle A be a right angle. Upon the hypotenuse BC describe the square BDFC; upon the side AB describe the square ALMB, and upon the side AC the square ARNC; the square BDFC is equal to the two squares ALMB, ARNC taken together.

Fig. 261.

Fig. 262.

Fig. 263.

Draw the right lines MC, AD, and draw AG parallel to BD.

Because the square or parallelogram MLAB and the triangle MCB are between the same parallels LC, MB, and have the same base MB, the triangle MCB is (Prop. 29.) equal to half the square ALMB.

Again, because the rectangle or parallelogram DGPB and the triangle DAB are between the same parallels GA and DB, and have the same base DB, the triangle DAB is (Prop. 29.) equal to half the rectangle DGBP.

Further, since the side MB of the triangle MBC and the side AB of the triangle ABD are sides of the same square, they are (Defin. 17.) equal. Also, since the side BC of the first triangle and the side BD of the second triangle are sides of the same square, they are equal. And because the angle MBC of the first triangle is composed of a right angle and the angle  $x$ , and the angle ABD of the second triangle is composed of a right angle and the same angle  $x$ , therefore these two angles, contained between the equal sides MB, BC and AB, BD, are equal. Wherefore the two triangles MBC, ABD, having two sides and the contained angle equal, are (Prop. 3.) identical, and consequently equal.

But the triangle MBC is half the square MLAB, and the triangle ABD is half the rectangle BDGP; the square and the rectangle are therefore equal.

In the same manner it may be demonstrated that the square ARNC and the rectangle CFGP are equal. Wherefore it follows that the whole square BDFC is equal to the two squares MLAB, ARNC taken together.

Fig. 264.

## CIRCLES.

908. DEFINITIONS. — 1. A right line (*fig. Prop. 33. AB*) terminated both ways by the circumference of a circle is called a *chord*.

2. A line (*fig. Prop. 39. AB*) which meets the circumference in one point only is called a *tangent*; and the point T is called the *point of contact*.

3. An angle (*fig. Prop. 33. ABD*) which has its vertex in the circumference of a circle is called an *angle in the circle*.

4. A part of a circle confined between two radii (*fig. Prop. 34. ACBFA*) is called a *sector*.

5. A part of a circle (*fig. Prop. 35. AGBDA*) terminated by a chord is called a *segment of a circle*.

909. PROP. XXXIII. *To draw the circumference of a circle through three given points.*

Let there be three given points, A, B, D (*fig. 265.*), through which it is required to draw the circumference of a circle. Draw the right lines AB, BD, and bisect them: from the points of the division F, G, raise the perpendiculars BC, GC; and at the point C with the radius CA describe the circumference of a circle; this circumference will pass through the points B and D. Draw the lines CA, CB, CD.

In the triangles CFA, CFB the side FA is equal to the side FB by construction, the side FC is common, and the two angles at F are right angles. These two triangles, then, have two sides and the angle contained by them equal; they are therefore (Prop. 3.) identical. Consequently the side CB is equal to the side CA.

For the same reason, the triangles CGB, CGD are also identical. Wherefore the side CD is equal to the side CB, and consequently equal to CA.

And since the right lines CB, CD are equal to the right line CA, it is manifest (Prop. 1.) that the circumference which passes through the point A must also pass through the point D.

Fig. 265.

910. PROP. XXXIV. *If a radius bisect a chord, it is perpendicular to that chord.*

If the radius CF (*fig. 266.*) bisect the chord AB, the angles CDA, CDB are right angles. Draw the radii CA, CB.

In the triangles CDA, CDB the sides CA, CB, being radii, are equal (Prop. 1.), the sides AD, DB are equal by supposition, and the side CD is common. These two triangles, having the three sides equal, are therefore (Prop. 5.) identical. Wherefore the angles CDA, CDB are equal, and consequently (Prop. 10.) are right angles.

COROLLARY. The two angles at C are also (Prop. 5.) equal.

Hence it appears, that any angle ACB may be bisected by describing from its vertex C as the centre with any radius AC an arc AFB; bisecting the chord of that arc AB; and then drawing from the point of division D the right line CD; for it may then be shown, as in the proposition, that the triangles ACD, DCB are identical, and consequently the angles at C equal.

Fig. 266.

911. PROP. XXXV. *To find the centre of a circle.*

Let the circle of which it is required to find the centre be AGBF. Draw any chord AB (fig. 267); bisect it, and from the point of division D raise a perpendicular FG: this line will pass through the centre, and consequently, if it be bisected, the point of division will be the centre.

If the centre of the circle be not in the line FG, it must be somewhere out of it; for instance, at the point L. But this is impossible, for if the point L were the centre, the right line LM would be a radius; and since this line bisects the chord AB, it is (Prop. 34.) perpendicular to AB; which cannot be, since CD is perpendicular to AB.

Fig. 267.

Fig. 268.

912. PROP. XXXVI. *To find the centre of an arc of a circle.*

Let ABDF be the arc of which it is required to find the centre. Draw any two chords AB, DF (fig. 268); bisect them, and from the points of division raise the perpendiculars MC, LC; the point C, in which these two perpendiculars cut each other, is the centre of the arc.

For (Prop. 35.) the perpendicular MC and the perpendicular LC both pass through the centre of the same circle; this centre must therefore be the point C, which is the only point common to the two perpendiculars.

913. PROP. XXXVII. *If three equal lines meet in the same point within a circle, and are terminated, they are radii of that circle.*

The lines CA, CB, CD (fig. 269.), drawn from the same point C within a circle, and terminated by it, being equal, the point C is the centre of the circle. Draw the lines AB, BD; bisect them, and let the points of division be F, G; and draw the lines CF, CG.

Fig. 269.

In the triangles CFA, CFB, the sides CA, CB are equal by supposition, the sides FA, FB are equal by construction, and the side CF is common. These two triangles, then, have the three sides equal; they are therefore (Prop. 5.) identical. Wherefore the two angles at F are equal, and the line FC (Defin. 11.) is perpendicular to the chord AB. And since this perpendicular bisects the chord AB, it must (Prop. 35.) pass through the centre of the circle. In like manner, it may be demonstrated that the line GC also passes through the centre. Wherefore the point C is the centre of the circle, and CA, CB, CD are radii.

914. PROP. XXXVIII. *If the radius of a circle be perpendicular to a chord, the radius bisects both the chord and the arc of the chord.*

Let the radius CF be perpendicular to the chord AB (fig. 270.); the right line AD is equal to the right line DB, and the arc AF equal to the arc FB. Draw the right lines CA, CB.

In the large triangle ACB, the side CA (Prop. 1.) is equal to the side CB, because they are radii of the same circle. The angle A is (Prop. 4.) therefore equal to the angle B. The angles at D are right angles, and therefore equal; and the angles at C are consequently (Prop. 23.) equal. Also the side CA is equal to the side CB, and the side CD is common. These two triangles, then, having two sides and the angle contained by them equal, are (Prop. 3.) identical, whence the side AD is equal to the side DB. Again, since the angles ACF, BCF are equal, the arcs AB, BF, which measure these angles, are also equal. The chord AB and the arc AFB are therefore bisected by the radius CF.

915. PROP. XXXIX. *A right line perpendicular to the extremity of a radius is a tangent to the circle.*

Let the line AB (fig. 271.) pass through the extremity of the radius CT in such a manner that the angles CTA, CTB shall be right angles; this line AB touches the circumference in only one point T. If AB touch the circumference in any other point, let it be D, and draw the line CD.

Fig. 271.

In the right-angled triangle CTD the square of the hypothenuse CD is equal to the two squares of CT and TD taken together. The square of CD is therefore greater than the square of CT, and consequently the line CD is greater than the line CT, which is a radius. Therefore the point D is out of the circumference. And in like manner it may be shown that every point in the line AB is out of the circumference, except T; AB is therefore a tangent to the circle.

COROLLARY. It follows, therefore, that a perpendicular is the shortest line that can be

drawn from any point to a given line; since the perpendicular CT is shorter than any other line which can be drawn from the point C to the line AB.

916. PROP. XL. *If a right line be drawn touching a circumference, a radius drawn to the point of contact will be perpendicular to the tangent.*

Let the line AB (fig. 272.) touch the circumference of a circle in a point T, the radius CT is perpendicular to the tangent AB. For all other lines drawn from the point C to the line AB must pass out of the circle to arrive at this line. The line CT is therefore the shortest which can be drawn from the point C to the line AB, and consequently (Corol. to Prop. 39.) is perpendicular to the line AB.

Fig. 272.

917. PROP. XLI. *The angle formed by a tangent and chord is measured by half the arc of that chord.*

Let BTA (fig. 273.) be a tangent and TD a chord drawn from the point of contact T; the angle ATD is measured by half the arc TFD, and the angle BTD is measured by half the arc TGD. Draw the radius CT to the point of contact, and the radius CF perpendicular to the chord TD.

The radius CF being perpendicular to the chord TD (Prop. 38.) bisects the arc TFD. TF is therefore half the arc TFD.

In the triangle CML the angle M being a right angle, the two remaining angles are (Prop. 22.) equal to a right angle. Wherefore the angle C is that which the angle L wants of a right angle. On the other side, since the radius CT is perpendicular to the tangent BA, the angle ATD is also that which the angle L wants of a right angle. The angle ATD is therefore equal to the angle C. But the angle C is measured by the arc TF, consequently the angle ATD is also measured by the arc TF, which is half of TFD. The angle BTD must therefore be measured by half the arc TGD, since these two halves of arcs make up half the circumference.

Fig. 273.

918. PROP. XLII. *An angle at the circumference of a circle is measured by half the arc by which it is subtended.*

Let CTD (fig. 274.) be the angle at the circumference; it has for its measure half the arc CFD by which it is subtended.

Fig. 274.

Suppose a tangent passing through the point T.

The three angles at T are measured by half the circumference (Prop. 22.), but the angle ATD is measured (Prop. 41.) by half the arc TD, and the angle BTC by half the arc TC; consequently the angle CTD must be measured by half the arc CFD, since these three halves of arcs make up half the circumference.

919. PROP. XLIII. *The angle at the centre of a circle is double of the angle at the circumference.*

Let the angle at the circumference ADB (fig. 275.) and the angle at the centre ACB be both subtended by the same arc AB, the angle ACB is double of the angle ADB.

For the angle ACB is measured by the arc AB, and the angle ADB is (Prop. 42.) measured by half the same arc AB; the angle ACB is therefore double of the angle ADB.

920. PROP. XLIV. *Upon a given line, to describe a segment of a circle containing a given angle.*

Let AB (fig. 276.) be the given line and G the given angle, it is required to draw such a circumference of a circle through the points A and B that the angle D shall be equal to the angle G.

For this purpose draw the lines AL, BL in such manner that the angles A and B shall be equal to the angle G; at the extremities of LA, LB raise the perpendiculars AB, BC; and from the point C in which these two perpendiculars cut each other, with the radius CA or CB describe the circumference ADB; the angle D will be equal to the angle G.

The angle LAB, formed by the tangent AL and the chord AB, is (Prop. 41.) measured by half the arc AFB; and the angle D at the circumference is also measured (Prop. 42.) by half the arc AFB; the angle D is therefore equal to the angle LAB. But the angle LAB is made equal to the angle G; the angle D is therefore equal to the angle G.

Fig. 276.

921. PROP. XLV. *In every triangle the greater side is opposite to the greater angle, and the greater angle to the greater side.*

In the triangle ABC (fig. 277.), if the side AB be greater than the side AC, the angle

C opposite to the side AB will be greater than the angle B opposite to the side AC. Draw the circumference of a circle through the three points A, C, B.

Since the chord AB is greater than the chord AC, it is manifest that the arc ADB is greater than the arc AFC; and consequently the angle at the circumference C, which is measured (Prop. 42.) by half the arc ADB, is greater than the angle at the circumference B, which is measured by half the arc AFC.

Again, if the angle C is greater than the angle B, the side AB opposite to the angle C will be greater than the side AC opposite to the angle B.

The angle C is measured (Prop. 42.) by half the arc ADB, and the angle B by half the arc AFC. But the angle C is greater than the angle B; the arc ADB is therefore greater than the arc AFC, and consequently the chord AB is greater than the chord AC.

922. PROP. XLVI. *Two parallel chords intercept equal arcs.*

If the two chords AB, CD (fig. 278.) are parallel, the arcs AC, BD are equal. Draw the right line BC.

Because the lines AB, CD are parallel, the alternate angles ABC, BCD are (Prop. 17.) equal. But the angle at the circumference BCD is measured (Prop. 42.) by half the arc AC; and the angle at the circumference BCD is measured by half the arc BD; the arcs AC, BD are therefore equal.

923. PROP. XLVII. *If a tangent and chord be parallel to each other, they intercept equal arcs.*

Let the tangent FG (fig. 279.) be parallel to the chord AB; the arc TA will be equal to the arc TB. Draw the right line TA.

Because the lines FG, AB are parallel, the alternate angles FTA, TAB are (Prop. 17.) equal. But the angle FTA, formed by a tangent and a chord, is measured (Prop. 41.) by half the arc TA, and the angle at the circumference TAB is measured (Prop. 42.) by half the arc TB. The halves of the arcs TA, TB, and consequently the arcs themselves, are therefore equal.

924. PROP. XLVIII. *The angle formed by the intersection of two chords is measured by half the two arcs intercepted by the two chords.*

Let the two chords AB, DF (fig. 280.) cut each other at the point C, the angle FCB or ACD is measured by half the two arcs FB, AD. Draw AG parallel to DF.

Because the lines AG, DF are parallel, the interior and exterior angles GAB, FCB are (Prop. 19.) equal. But the angle at the circumference GAB is measured (Prop. 42.) by half the arc GFB. The angle FCB is therefore also measured by half the arc GFB.

Because the chords AG, DF are parallel, the arcs GF, AD are (Prop. 46.) equal: AD may therefore be substituted in the room of GF; wherefore the angle FCB is measured by half the arcs AD, FB.

925. PROP. XLIX. *The angle formed by two secants is measured by half the difference of the two intercepted arcs.*

Let the angle CAB (fig. 281.) be formed by the two secants AC, AB, this angle is measured by half the difference of the two arcs GD, CB, intercepted by the two secants. Draw DF parallel to AC.

Because the lines AC, DF are parallel, the interior and exterior angles CAB, FDB are (Prop. 19.) equal. But the angle FDB is measured (Prop. 42.) by half the arc FB; the angle GAB is therefore also measured by half the arc FB.

Because the chords GC, DF are parallel, the arcs GD, CF are (Prop. 46.) equal; the arc FB is therefore the difference of the arc GD and the arc CFB. Where the angle A has for its measure half the difference of the arcs GD, CFB.

926. PROP. L. *The angle formed by two tangents is measured by half the difference of the two intercepted arcs.*

Let the angle CAB (fig. 282.) be formed by the two tangents AC, AB; this angle is measured by half the difference of the two arcs GLD, GFD. Draw DF parallel to AC.

Because the lines AC, DF are parallel, the interior and exterior angles CAB, FDB are (Prop. 19.) equal. But the angle FDB, formed by the tangent DB and the chord DF, is measured (Prop. 41.) by half the arc FD. Therefore the angle CAB is also measured by half the arc FD.

Fig. 277.

Fig. 278.

Fig. 279.

Fig. 280.

Fig. 281.

Because the tangent AC and the chord DF are parallel, the intercepted arcs GF GD are (Prop. 47.) equal. The arc FD is therefore the difference between the arc GLD and the arc GFD. Therefore the angle CAB, which is measured by half the arc FD, is also measured by half the difference of the arcs GLD, GFD.

Fig. 282.

Fig. 283.

**COROLLARY.** In the same way it may be demonstrated that the angle formed by a tangent ATC (fig. 283.) and a secant ADB is measured by half the difference of the two intercepted arcs.

927. **PROP. LI.** *To raise a perpendicular at the extremity of a given line.*

At the extremity A (fig. 284.) of the given line AB let it be required to raise a perpendicular.

From any point C taken above the line AB describe a circumference passing through the point A and cutting the line AB in any other point, as G. Draw the diameter DG and the right line AD; this line AD will be perpendicular to the line AB.

The angle DAG at the circumference is measured (Prop. 42.) by half the arc DFG, which is half the circumference, because DCG is a diameter. The angle DAG is therefore measured by one fourth part of the circumference, and consequently (Defin. 10.) is a right angle, whence the line AD is (Prop. 11.) perpendicular to the line AB.

**COROLLARY.** Hence it follows that the angle at the circumference which is subtended by a diameter must be a right angle.

928. **PROP. LII.** *From any point without a circle to draw a tangent to that circle.*

From the point A (fig. 285.) let it be required to draw a tangent to the circle DTB.

Draw from the centre C any right line CA; bisect this right line, and from the point of division B, as a centre, describe the arc CTA. Lastly, from the point A, and through the point T, in which the two arcs cut each other, draw the right line AT; this right line AT will be a tangent to the circle DTB. Draw the radius CT.

The angle CTA at the circumference, being subtended by the diameter CA, is (Corol. to Prop. 51.) a right angle; therefore the line TA is perpendicular to the extremity of the radius CT, and consequently (Prop. 40.) is a tangent to the circle DTB.

Fig. 285.

#### SURFACES.

929. **DEFINITIONS.**—1. A *mathematical point* has neither length, breadth, nor thickness. The *physical point*, now for consideration, has a supposed length and breadth exceedingly small.

2. A *physical line* is a series of physical points, and consequently its breadth is equal to that of the physical points whereof it is composed.

3. Since physical lines are composed of points, as numbers are composed of units, points may be called the *units* of lines.

4. As to multiply one number by another is to take or repeat the first number as many times as there are units in the second; so to *multiply one line by another* is to take or repeat the first line as many times as there are units, that is, physical points, in the second.

930. **PROP. LIII.** *The surface of a rectangle is equal to the product of its two sides.*

Let the rectangle be ABCD (fig. 286.). If the physical line AB be multiplied by the physical line AD, the product will be the surface ABCD.

If as many physical lines equal to AB as there are physical points in the line AD be raised perpendicularly upon AD, these lines AB, ab, &c. will fill up the whole surface of the rectangle ABCD. Wherefore the surface ABCD is equal to the line AB taken as many times as there are physical points in the line AD; that is, (Defin. 4.) equal to the line AB multiplied by the line AD.

931. **PROP. LIV.** *The surface of a triangle is equal to half the product of its altitude and base.*

If from the vertex of any angle A (fig. 287.) of the triangle BAC be drawn AD, per-

Fig. 286.

pendicular to the opposite side BC, this perpendicular is called the *height*, and the side BC the *base* of the triangle. Now the surface of the triangle is equal to half the product of the height AD and the base BC.

Produce BC both ways; through the point A draw FG parallel to BC, and raise the two perpendiculars BF, CG.

Because the rectangle BFGC and the triangle BAC are between the same parallels, and have the same bases, the triangle is (Prop. 29.) half the rectangle. But the surface of the rectangle is equal (Prop. 53.) to the product of BF and BC. Wherefore the surface of the triangle is equal to half the product of BF and BC, that is, of DA and CC.

Fig. 287.

932. PROP. LV. To measure the surface of any rectilinear figure.

Let ABCDFA (fig. 288.) be the rectilinear figure, whereof it is required to find the surface.

Divide the whole figure into triangles by drawing the lines CA, CF. Then, drawing a perpendicular from the point B to the side CA, multiply these two lines; the half of their product will (Prop. 54.) give the surface of the triangle ABC. In the same manner let the surfaces of the remaining triangles ACF, FCD be found. These three surfaces added together will give the whole surface of the figure ABCDFA.

Fig. 288.

933. PROP. LVI. The area of a circle is equal to half the product of its radius and circumference.

If the radius of the circle C (fig. 289.) be multiplied by its circumference, the half of the product will give the surface of the circle.

Two physical points being manifestly not sufficient to make a curve line, this must require at least three. If, therefore, all the physical points of a circumference be taken two by two, these will compose a great number of small right lines. From the extremities L, M of one of these small right lines if two radii LC MC be drawn, a small triangle LCM will be formed, the surface of which will be equal to half the product of its height; that is, the radius and its base.

Fig. 289.

To find the surface of all the small triangles whereof the circle is composed, multiply the height, that is, the radius, by all the bases, that is, by the circumference, and take the half of the product; whence the area or surface of the circle will be equal to half the product of the radius and circumference.

934. PROP. LVII. To draw a triangle equal to a given circle.

Let it be required to form a triangle the surface of which shall be equal to that of the circle AGFDA (fig. 290.).

At the extremity of any radius CA of the circle, raise a perpendicular AB equal to the circumference AGFD, and draw the right line CB. The surface of the triangle BCA will be equal to that of the circle AGFDA.

Fig. 290.

The surface of the circle is equal (Prop. 56.) to half the product of the radius CA and the circumference, or the line AB. The surface of the triangle is also equal (Prop. 54.) to half the product of its height CA, or radius, and its base BA, or circumference. Therefore the surface of the triangle is equal to that of the circle.

# PROPORTION.

935. DEFINITIONS. — 1. The ratio of one quantity to another is the number of times which the first contains the second; thus the ratio of 12 to 3 is four, because 12 contains 3 four times; or, more universally, *ratio* is the comparative magnitude of one quantity with respect to another.

2. Four quantities are *proportional*, or *in geometrical proportion*, or two quantities are said to have the same ratio with two others, when the first contains or is contained in the second, exactly the same number of times which the third contains or is contained in the fourth; thus, the four numbers 6, 3, 8, 4 are proportionals, because 6 contains 3 as many times as 8 contains 4, and 3 is contained in 6 as many times as 4 is contained in 8, that is, twice; which is thus expressed: 6 is to 3 as 8 to 4; or 3 is to 6 as 4 to 8.

936. PROP. LVIII. Parallelograms which are between the same parallels are to one another as their bases.

Let the two parallelograms  $ABCD$ ,  $FGLM$  (*fig. 291.*) be between the same parallels  $BL$ ,  $AM$ , the surface of the parallelogram  $ABCD$  contains the surface of the parallelogram  $FGLM$  as many times exactly as the base  $AD$  contains the base  $FM$ . Suppose, for example, that the base  $AD$  is triple of the base  $FM$ ; in this case the surface  $ABCD$  will also be triple of the surface  $FGLM$ .

Divide the base  $AD$  into three parts, each of which is equal to the base  $FM$ , and draw from the points of division the lines  $NP$ ,  $RS$  parallel to the side  $AB$ .

The parallelograms  $ABPN$ ,  $FGLM$  being between the same parallels and having equal bases, the parallelogram  $ABPN$  is (Prop. 30.) equal to the parallelogram  $FGLM$ . For the same reason, the parallelograms  $NPSR$ ,  $RSCD$  are also equal to the parallelogram  $FGLM$ . The parallelogram  $ABCD$  is therefore composed of three parallelograms, each of which is equal to the parallelogram  $FGLM$ . Consequently the parallelogram  $ABCD$  is triple of the parallelogram  $FGLM$ .

937. PROR. LIX. *Triangles which are between the same parallels are to one another as their bases.*

Let the two triangles  $ABC$ ,  $DFG$  (*fig. 292.*) be between the same parallels  $LF$ ,  $AG$ , the surface of the triangle  $ABC$  contains the surface of the triangle  $DFG$  as many times as the base  $AC$  contains the base  $DG$ . Suppose, for example, that the base  $AC$  is triple of the base  $DG$ , in this case the surface  $ABC$  will be triple of the surface  $DFG$ .

Divide the base  $AC$  into three equal parts,  $AN$ ,  $NR$ ,  $RC$ , each of which is equal to the base  $DG$ , and draw the right lines  $BN$ ,  $BR$ .

The triangles  $ABN$ ,  $DFG$  being between the same parallels and having equal bases, the triangle  $ABN$  is (Prop. 31.) equal to the triangle  $DFG$ . For the same reason, the triangles  $NBR$ ,  $RBC$  are each equal to the triangle  $DFG$ . The triangle  $ABC$  is therefore composed of three triangles, each of which is equal to the triangle  $DFG$ . Wherefore the triangle  $ABC$  is triple of the triangle  $DFG$ .

938. PROR. LX. *If a line be drawn in a triangle parallel to one of its sides, it will cut the other two sides proportionally.*

In the triangle  $BAC$  (*fig. 293.*), if the line  $DF$  be parallel to the side  $BC$ , it will cut the other two sides in such manner that the segment  $AD$  will be to the segment  $DB$  as the segment  $AF$  is to the segment  $FC$ . Suppose, for instance, the segment  $AD$  to be triple of the segment  $DB$ , the segment  $AF$  will be triple of the segment  $FC$ . Draw the diagonals  $DC$ ,  $FB$ .

The triangles  $AFD$ ,  $DFB$  are between the same parallels, as will be easily conceived by supposing a line drawn through the point  $F$  parallel to the side  $AB$ . These two triangles are therefore to one another (Prop. 59.) as their bases; and since the base  $AD$  is triple of the base  $DB$ , the triangle  $AFD$  will be triple of the triangle  $DFB$ .

Again, the triangles  $BFD$ ,  $FDC$  are between the same parallels  $DF$ ,  $BC$ , and upon the same base  $DF$ . These two triangles are therefore (Prop. 31.) equal; and since the triangle  $AFD$  is triple of the triangle  $DFB$ , it will also be triple of the triangle  $FDC$ .

Lastly, the triangles  $ADF$ ,  $FDC$  are between the same parallels, as will be easily conceived by supposing a line drawn through the point  $D$  parallel to the side  $AC$ . These two triangles are therefore to one another (Prop. 59.) as their bases; and since the triangle  $ADF$  is triple of the triangle  $FDC$ , the base  $AF$  will be triple of the base  $FC$ .

939. PROR. LXI. *Equiangular triangles have their homologous sides proportional.*

In the two triangles  $ABC$ ,  $CDF$  (*fig. 294.*), if the angle  $A$  be equal to the angle  $C$ , the angle  $B$  equal to the angle  $D$ , and the angle  $C$  equal to the angle  $F$ ; the side  $AC$ , for example, opposite to the angle  $B$  is to the side  $CF$  opposite to the angle  $D$  as the side  $AB$  opposite to the angle  $C$  is to the side  $CD$  opposite to the angle  $F$ . Place the two triangles so that the sides  $AC$ ,  $CF$  shall form one right line, and produce the sides  $AB$ ,  $FD$  till they meet in  $G$ .

The interior and exterior angles  $GAF$ ,  $DCF$  being equal, the lines  $GA$ ,  $DC$  are (Prop. 20.) parallel. In like manner, the alternate angles  $GFA$ ,  $BCA$  on the same sides being equal, the lines  $GF$ ,  $BC$  are (Prop. 20.) parallel. Wherefore the quadrilateral figure  $BGDC$  is a parallelogram, and consequently its opposite sides are equal. In the triangle  $GAF$  the line  $BC$ , being parallel to the side

Fig. 291.

Fig. 292.

Fig. 293.

Fig. 294.

FG, cuts (Prop. 60.) the other two sides proportionally; that is, AC is to CP as AB is to BG, or its equal CD.

940. PROP. LXII. *Triangles the sides of which are proportional are equiangular.*

In the two triangles BAC, FDG (fig. 295.), if the side AB is to the side DF as the side BC is to the side FG and as the side AC to the side DG, these two triangles have their angles equal.

Let the side AB be supposed triple of the side DF; the side AC must be triple of the side DG, and the side BC triple of the side FG.

If the triangle FDG be not equiangular with the triangle BAC, another triangle may be formed equiangular with it; for example, FLG. But this is impossible; for if the two triangles BAC, FLG were equiangular, their sides would be (Prop. 61.) proportional; and BC being triple of FG, AB would be triple of LF. But AB is triple of DF; whence LF would be equal to DF. For the same reason, LG would be equal to DG. Thus, the two triangles FLG, FDG, having their three sides equal, would be (Prop. 5.) identical; which is absurd, since their angles are unequal.

941. PROP. LXIII. *Triangles which have an angle in one equal to an angle in the other, and the sides about these angles proportional, are equiangular.*

If in the two triangles BAC, NMP (fig. 296.) the angle A be equal to the angle M, and the side AB be to the side MN as the side AC is to the side MP, the two triangles are equiangular.

If AB be triple of MN, AC must be triple of MP. Now, if the angle MNP, for example, is not equal to the angle ABC, another angle may be made, as MNR, which shall be equal to it. But this is impossible; for the two triangles BAC, NMR, having two angles equal, would be equiangular, and consequently (Prop. 61.) would have their sides proportional; wherefore, AB being triple of MN, AC would be triple of MR, which cannot be, since AC is triple of MP.

942. PROP. LXIV. *A right line which bisects any angle of a triangle divides the side opposite to the bisected angle into two segments, which are proportional to the two other sides.*

In the triangle BAC, let the angle BAC be bisected by the right line AD, making the angle  $r$  equal to the angle  $s$ . The segment BD is to the segment DC as the side BA to the side AC.

Produce the side BA, and draw CF parallel to DA.

The lines DA, CF being parallel, the interior and exterior angles  $r$ ,  $F$  are (Prop. 19.) equal, and the alternate angles  $s$ ,  $C$  are (Prop. 17.) also equal. And since the angle  $r$  is equal to the angle  $s$ , the angle  $F$  will also be equal to the angle  $C$ ; and consequently the side AF is equal to the side AC.

In the triangle BFC, the line AD being parallel to the side FC; BD (Prop. 60.) will be to DC as BA is to AF, or its equal AC.

943. PROP. LXV. *To find a fourth proportional to three given lines.*

Let the three lines be A, B, C (fig. 298.), it is required to find a fourth line D, such that the line A shall be to the line B as the line C is to the line D.

Form any angle RFG, make FM equal to the line A, MG equal to the line B, and FN equal to the line C; draw the right line MN, and through the point G draw GL parallel to MN; NL will be the fourth proportional required.

In the triangle FLG the line NM, being parallel to the side LG, cuts the other two sides (Prop. 60.) proportionally. Wherefore FM is to MG as FN is to NL; that is, A is to B as C is to D.

944. PROP. LXVI. *To find a third proportional to two given lines.*

Let the two lines be A, B (fig. 299.), it is required to find a third line C, such that the line A shall be to the line B as the line B is to the line C.

Form any angle LFG, make FM equal to the line A, MG equal to the line B, and FN equal to the line B; draw the right line MN, and through the point G draw GL parallel to MN; NL will be the third proportional required.

In the triangle FLG the line NM, being parallel to the side LG, cuts the other two

Fig. 295.

Fig. 296.

Fig. 297.

Fig. 298.

Fig. 299.

sides (Prop. 60.) proportionally. Wherefore FM is to MG as FN is to NL; that is, A is to B as B is to C.

945. PROP. LXVII. *If four lines be proportional, the rectangle or product of the extremes is equal to the rectangle or product of the means.*

Let the line A be to the line B as the line C is to the line D (fig. 300.); the rectangle formed by the lines A and D is equal to the rectangles formed by the lines B and C

Let the four lines meet in a common point, forming at that point four right angles; and draw the lines parallel to them to complete the rectangles  $x$ ,  $y$ ,  $z$ .

If the line A be triple of the line B, the line C will be triple of the line D.

The rectangles or parallelograms  $x$ ,  $z$  being between the same parallels, are to one another as their bases. Since the base A is triple of the base B, the rectangle  $x$  is triple of the rectangle  $z$ . In like manner, the rectangles or parallelograms  $y$ ,  $z$ , being between the same parallels, are to one another as their bases: since the base C is triple of the base D, the rectangle  $y$  is therefore triple of the rectangle  $z$ . Wherefore, the rectangle  $x$  being triple of the rectangle  $z$ , and the rectangle  $y$  being triple of the same rectangle  $z$ , these two rectangles  $x$  and  $y$  are equal to one another.

946. PROP. LXVIII. *Four lines which have the rectangle or product of the extremes equal to the rectangle or product of the means are proportional.*

Let the four lines A, B, C, D (fig. 301.) be such that the rectangle of A and D is equal to the rectangle of B and C, the line A will be to the line B as the line C to the line D.

Let the four lines meet in a common point, forming at that point four right angles, and complete the rectangles  $x$ ,  $y$ ,  $z$ .

If the line A be triple of the line B, the line C will be triple of the line D.

The rectangles  $x$  and  $z$ , being between the same parallels, are to one another as their bases: since the base A is triple of the base B, the rectangle  $x$  will be therefore triple of the rectangle  $z$ . And the rectangle  $y$  is, by supposition, equal to the rectangle  $x$ ; the rectangle  $y$  is therefore also triple of the rectangle  $z$ .

But the rectangles  $y$ ,  $z$ , being between the same parallels, are to one another as their bases. Hence, since the rectangle  $y$  is triple of the rectangle  $z$ , the base C is also triple of the base D.

947. PROP. LXIX. *If four lines be proportional, they are also proportional alternately.*

If the line A is to the line B as the line C to the line D (fig. 302.), they will be in proportion alternately; that is, the line A will be to the line C as the line B to the line D.

Because the line A is to the line B as the line C is to the line D, the rectangle of the extremes A and D is equal to the rectangle of the means B and C; whence it follows (Prop. 68.) that the line A is to the line C as the line B is to the line D.

Otherwise, — Suppose the line A to be triple of the line B, the line C will be triple of the line D. Hence, instead of saying A is to B as C to D, we may say three times B is to B as three times D is to D. Now it is manifest that three times B is to three times D as B is to D. Therefore the line A (which is equal to three times B) is to the line C (which is equal to three times D) as the line B is to the line D.

948. PROP. LXX. *If four lines be proportional, they will be proportional by composition.*

Let the line A be to the line B as the line C is to the line D (fig. 303.), they will be proportional by composition; that is, the line A joined to the line B will be to the line B as the line C joined to the line D is to the line D.

If the line A contain the line B, for example, three times, and the line C contain the line D three times; the line A joined to the line B will contain the line B four times, and the line C joined to the line D will contain the line D four times. Therefore the line A joined to the line B is to the line B as the line C joined to the line D is to the line D.

949. PROP. LXXI. *If four lines be proportional, they will be also proportional by division.*

If the line A is to the line B as the line C is to the line D (fig. 304.), they will be proportional by division; that is, the line A wanting the line B is to the line B as the line C wanting the line D is to the line D.

If the line A contain the line B, for example, three times, and the line C contain the line D three times, the line A wanting the line B will contain the line B only twice; and the line C wanting the line D will also contain the line D

Fig. 300.

Fig. 301.

Fig. 302.

Fig. 303.

Fig. 304.

twice. Therefore the line A wanting the line B is to the line B as the line C wanting the line D is to the line D.

950. PROP. LXXII. *If three lines be proportional, the first is to the third as the square of the first is to the square of the second.*

If the line CD is to the line  $cd$  as the line  $cd$  is to a third line  $x$  (fig. 305.), the line CD is to the line  $x$  as the square of the line CD is to the square of the line  $cd$ . Take CF equal to the line  $x$ , and draw the perpendicular FB.

Fig. 305.

Since the line CD is to the line  $cd$  as the line  $cd$  is to the line CF, the rectangle of the extremes CF, CD, or CL is equal (Prop. 67.) to the rectangle of the means, that is, to the square of  $cd$ .

Again, the square of CD and the rectangle of the lines CF, CL, being between the same parallels, are to one another (Prop. 58.) as their bases. Therefore CD is to CF, or  $x$ , as the square of CD is to the rectangle of CF and CL, or to its equal the square of  $cd$ .

951. PROP. LXXIII. *If two chords in a circle cut each other, the rectangle of the segments of one is equal to the rectangle of the segments of the other*

Let the two chords AB, CD (fig. 306.) in the circle cut each other in the point F, the rectangle of AF, FB is equal to the rectangle of CF, FD. Draw the two right lines AC, DB. Because in the triangles CAF, BDF the angles at the circumference A and D are both measured (Prop. 42.) by half the arc CB, they are equal. Because the angles C and B are both measured (Prop. 42.) by half the arc AD, these angles are also equal. And the angles at F are equal, because they are vertical. These two triangles are therefore equiangular, and consequently (Prop. 61.) their sides are proportional. Wherefore the side AF opposite to the angle C is to the side FD opposite to the angle B as the side CF opposite to the angle A is to the side FB opposite to the angle D. Therefore (Prop. 69.) the rectangle of the extremes AF, FB is equal to the rectangle of the means CF, FD.

Fig. 306.

952. PROP. LXXIV. *To find a mean proportional between two given lines.*

Let there be two lines A, C (fig. 307.), it is required to find a third line B, such that the line A shall be to the line B as the line B is to the line C.

Fig. 307.

Place the lines A and C in such manner that they shall form one right line DGL, and bisect this right line in the point F. From the point F, as a centre, describe the circumference of a circle DMLN; then, at the point G, where the two lines are joined, raise the perpendicular GM; GM is the mean proportional sought between the lines A and C. Produce MG to N.

Because the chords DL, MN cut each other at the point G, the rectangle of the segments DG, GL is (Prop. 73.) equal to the rectangle of the segments MG, GN.

Because the radius FL is perpendicular to the chord MN, FL (Prop. 38.) bisects MN; therefore GN is equal to GM.

Lastly, because the rectangle of the extremes DG, GL is equal to the rectangle of the means GM, GN, or its equal GM, DG is to GM as GM is to GL. Therefore GM is a mean proportional between DG and GL, that is, between the lines A and C.

953. PROP. LXXV. *The bases and altitudes of equal triangles are in reciprocal or inverse ratio.*

Let the two triangles ABC, DFG (fig. 308.) be equal; the base AC will be to the base DG, as the perpendicular FM to the perpendicular BL; that is, the bases and altitudes are in reciprocal or inverse ratio.

The triangle ABC (Prop. 54.) is half the product or rectangle of the base AC and the altitude BL. Again, the triangle DFG is (Prop. 54.) half the product or rectangle of the base DG and the altitude FM. The two triangles being equal, the two rectangles, which are double of the triangles, will therefore also be equal.

Again, because the rectangle of the extremes AC, BL is equal to the rectangle of the means DG, FM; AC (Prop. 68.) is to DG as FM is to BL.

Fig. 308.

954. PROP. LXXVI. *Triangles the bases and altitudes whereof are in reciprocal or inverse ratio are equal.*

In the two triangles ABC, DFG (fig. 309.), if the base AC be to the base DG as the perpendicular FM to the perpendicular BL, the surfaces of the two triangles are equal.

Because AC is to DG as FM is to BL, the product or rectangle of the extremes AC, BL is (Prop. 67.) equal to the product or rectangle of the means DG, FM. The halves (Corol. to Prop. 27.) of these two rectangles, namely, triangles ABC, DFG, are therefore equal.

955. PROP. LXXVII. *Two secants drawn from the same point to a circle are in the inverse ratio of the parts which lie out of the circle.*

Let the two secants be CA, CB (fig. 310.); CA is to CB as CD is to CF. Draw the right lines FB, DA.

In the triangles CDA, CFB the angles at the circumference A and B, being both measured (Prop. 42.) by half the arc FD, are equal, and the angle C is common to the two triangles. These two triangles are therefore (Prop. 23.) equiangular and (Prop. 61.) have their sides proportional. Wherefore the side CA of the first triangle is to the side CB of the second triangle as the side CD of the first triangle is to the side CF of the second triangle.

956. PROP. LXXVIII. *The tangent to a circle is a mean proportional between the secant and the part of the secant which lies out of the circle.*

In the circle ABD, CB (fig. 311.) being secant, and CA tangent, CB is to CA as CA is to CD. Draw the right lines AB, AD.

The triangles CAB, CDA have the angle C common to both. Also the angle B is measured (Prop. 42.) by half the arc AFD; and the angle CAD formed by the tangent AC and the chord AD is measured (Prop. 41.) by half the same arc AFD. The two triangles CAB, CDA, having their two angles equal, are (Prop. 23.) equiangular, and consequently (Prop. 61.) have their sides proportional. Hence the side CB of the greater triangle opposite to the angle CAB is to the side CA of the smaller triangle opposite to the angle D as the side CA of the greater triangle opposite to the angle B is to the side CD of the smaller triangle opposite to the angle A.

COROLLARY. From this proposition is suggested a new method of finding a mean proportional between two given lines.

Take CB equal to one of the given lines, and CD equal to the other; bisect DB; from the point of division, as a centre, describe the circumference DAB; and draw the tangent CA. This tangent is a mean proportional between CB and CD, as appears from the proposition.

957. PROP. LXXIX. *To cut a given line in extreme and mean ratio.*

Let it be required to divide the line CA (fig. 312.) in extreme and mean ratio; that is, to divide it in such a manner that the whole line shall be to the greater part as the greater part is to the less.

At the extremity A of the line CA raise a perpendicular AG equal to half the line CA; from the point G, as a centre, with the radius GA, describe the circumference ADB; draw the line CB through the centre, and take CF equal to CD; the line CA will be divided at the point F in extreme and mean ratio.

Because (Prop. 78.) CB is to CA as CA is to CD, by division, (Prop. 71.) CB wanting CA or its equal DB is to CA, as CA wanting CD or its equal CF is to CD; that is, CD or CF is to CA, as FA is to CD or CF; or, inversely, CA is to CF as CF is to FA, or the line AC is cut in extreme and mean ratio.

Fig. 309.

Fig. 310.

Fig. 311.

Fig. 312.

## SIMILAR FIGURES.

958. DEFINITIONS. — 1. Figures are *similar* which are composed of an equal number of physical points disposed in the same manner. Thus, the figures ABCDE, abcde (fig. 313.) are similar, if every point of the first figure has its corresponding point placed in the same manner in the second.

Hence it follows, that if the first figure is, for example, three times greater than the second, the points of which it is composed are three times greater than those of the second figure.

2. In similar figures, those lines are said to be *homologous* which are composed of an equal number of corresponding points.

Fig. 313.

959. PROP. LXXX. *In similar figures the homologous sides are proportional.*

Let the similar figures be  $ABCD$ ,  $abcd$  (*fig. 314.*), and the homologous lines  $CA$ ,  $ca$ ,  $CF$ ,  $cf$ :  $CA$  is to  $CF$  as  $ca$  to  $cf$ .

Since the lines CA, *ca* are homologous, they are composed of an equal number of corresponding points ; as are also the homologous lines CF, *cf*. If, for instance, the line CA is composed of 40 equal points, and the line CF of 30, the line *ca* will necessarily be composed of 40 points, and the line *cf* of 30 ; and it is manifest that 40 is to 30 as 40 to 30. Therefore CA is to CF as *ca* to *cf*.

**Fig. 314.**

960. PROP. LXXXI. *The circumferences of circles are as their radii.*

The circumference DCB (*fig.* 315.) is to the radius AB as the circumference *deb* is to the radius *ab*.

All circles are similar figures, that is, are composed of an equal number of points disposed in the same manner. They have therefore (Prop. 80.) their homologous lines proportional. Therefore the circumference  $DCB$  is to the radius  $AB$  as the circumference  $dcb$  is to the radius  $ab$ .

**Fig. 315.**

961. PROP. LXXXII. *Similar figures are to each other as the squares of their homologous sides.*

Let the two similar figures be  $A, a$  (*fig. 316.*) Upon the homologous sides  $CD, cd$  form the squares  $B, b$ . The surface  $A$  is to the surface  $a$  as the square  $B$  is to the square  $b$ . FIG. 315.

Since the figures  $A, a$  are similar, they are composed of an equal number of corresponding points; and since the homologous sides  $CD, cd$  are composed of an equal number of points, the squares drawn upon these lines  $B, b$  are also composed of an equal number of points.

**Fig. 316.**

If it be supposed that the surface A is composed of 1000 points and the square B of 400 points, the surface A will be also composed of 1000 points and the square b of 400. Now it is manifest that 1000 is to 400 as 1000 to 400. Wherefore the surface A is to the square B as the surface a is to the square b; and, alternately (Prop. 69.), the surface A is to the surface a as the square B to the square b.

**COROLLARY.** It follows that if any three similar figures be formed upon the three sides of a right-angled triangle, the figure upon the hypotenuse will be equal to the other two taken together; for these three figures will be as the squares of their sides; therefore, since the square of the hypotenuse is equal to the two squares of the other sides, the figure formed upon the hypotenuse will also be equal to the two other similar figures formed upon the other sides.

962. PROP. LXXXIII. *Circles are to each other as the squares of their radii.*

Let two circles DCB, *dcb* (*fig.* 317.) be drawn.

The surface contained within the circumference DCB is to the surface contained within the circumference *dcb* as the square formed upon the radius AB to the square formed upon the radius *ab*.

**Fig. 317.**

The two circles, being similar figures, are composed of an equal number of corresponding points, and the radii  $AB, ab$  being composed of an equal number of points, the squares of these radii will also be composed of an equal number of points. Suppose, for example, that the greater circle  $DCB$  is composed of 800 points, and the square of the greater radius  $AB$  of 300 points, the smaller circle  $deb$  will also be composed of 800 points, and the square of the smaller radius of 300. Now it is manifest that 800 is to 300 as 800 to 300. Therefore the greater circle  $DCB$  is to the square of its radius  $AB$  as the smaller circle  $deb$  is to the square of its radius  $ab$ ; and, alternately, the greater circle is to the lesser circle as the greater square is to the lesser square.

963. PROP. LXXXIV. *Similar triangles are equiangular.*

If the two triangles  $ABC, abc$  (*fig. 318.*) be composed of an equal number of points disposed in the same manner, they are equiangular.

For, since the triangles  $ABC, abc$  are similar figures, they have their sides (Prop. 80.) proportional; they are therefore (Prop. 62.) equiangular.

**Fig. 318.**

964. PROP. LXXXV. *Equiangular triangles are similar*  
If the triangles ABC, *abc* are equiangular, they are also similar. See fig. 318.

If the triangle  $ABC$  were not similar to the triangle  $abc$ , another triangle might be formed upon the line  $AC$ ; for example,  $ADC$ , which should be similar to the triangle  $abc$ . Now, the triangle  $ADC$ , being similar to the triangle  $abc$ .

will also (Prop. 84.) be equiangular to  $abc$ ; which is impossible, since the triangle  $ABC$  is supposed equiangular to  $abc$ .

965. PROP. LXXXVI. *If four lines are proportional, their squares are also proportional.*

If the line  $AB$  be to the line  $AC$  as the line  $AD$  is to the line  $AF$  (fig. 319.), the square of the line  $AB$  will be to the square of the line  $AC$  as the square of the line  $AD$  is to the square of the line  $AF$ .

With the lines  $AB$  and  $AD$  form an angle  $BAD$ ; with the lines  $AC$  and  $AF$  form another angle  $CAF$  equal to the angle  $BAD$ , and draw the right lines  $BD, CF$ .

Because  $AB$  is to  $AC$  as  $AD$  to  $AF$ , and the contained angles are equal, the two triangles  $BAD, CAF$  have their sides about equal angles proportional; they are therefore (Prop. 63.) equiangular, and consequently (Prop. 85.) similar: whence they are to one another (Prop. 82.) as the squares of their homologous sides. If, then, the triangle  $BAD$  be a third part of the triangle  $CAF$ , the square of the side  $AB$  will be a third part of the square of the side  $AC$ , and the square of the side  $AD$  will be a third part of the square of the side  $AF$ . Wherefore these four squares will be proportional.

966. PROP. LXXXVII. *Similar rectilineal figures may be divided into an equal number of similar.*

Let the similar figures be  $ABCDF, abcdf$ , and draw the homologous lines  $CA, ca, CF, cf$ ; these two figures will be divided into an equal number of similar triangles.

The triangles  $BCA, bca$  (fig. 320.), being composed of an equal number of corresponding points, are similar. The triangles  $ACF, acf$  and the triangles  $FCD, fcd$  are also, for the same reason, similar. Wherefore the similar figures  $ABCDF, abcdf$  are divided into an equal number of similar triangles.

967. PROP. LXXXVIII. *Similar figures are equiangular.*

The similar figures  $ABCDF, abcdf$  (see fig. preced. Prop.) have their angles equal. Draw the homologous lines  $CA, ca, CF, cf$ . The triangles  $BCA, bca$  are similar, and consequently equiangular. Therefore the angle  $B$  is equal to the angle  $b$ , the angle  $BAC$  to the angle  $bac$ , and the angle  $BCA$  to the angle  $bca$ . The triangles  $ACF, acf, FCD, fcd$  are also equiangular, because they are similar. Therefore all the angles of the similar figures  $ABCDF, abcdf$  are equal.

968. PROP. LXXXIX. *Equiangular figures the sides of which are proportional are similar.*

If the figures  $ABCDF, abcdf$  (fig. 321.) have their angles equal and their sides proportional, they are similar. Draw the right lines  $CA, ca, CF, cf$ .

The triangles  $CBA, cba$ , have two sides proportional and the contained angle equal; they are therefore (Prop. 63.) equiangular, and consequently (Prop. 85.) similar. The lines  $CA, ca$  are therefore (Prop. 80.) proportional.

The triangles  $CAF, caf$  have two sides proportional and the contained angle equal; for if from the equal angles  $BAF, baf$  be taken the equal angles  $BAC, bac$ , there will remain the equal angles  $CAF, caf$ . These two triangles are therefore equiangular, and consequently similar. In the same manner it may be proved that the triangles  $CFD, cfd$  are similar.

The two figures  $ABCDF, abcdf$  are then composed of an equal number of similar triangles; that is, they are composed of an equal number of points disposed in the same manner, or are similar.

#### PLANES.

969. DEFINITIONS. — 1. A plane is a surface, such that if a right line applied to it touches it in two points it will touch it in every other point. The surface of a fluid at rest, or of a well-polished table, may be considered as a plane.

2. A right line is *perpendicular* to a plane if it make right angles with all lines which can be drawn from any point in that plane. Thus  $BA$  (fig. 322.) is perpendicular to the plane  $MLGFPN$ , because it makes right angles with the lines  $AM, AL, AG$ , &c. drawn from the point  $A$ .

3. Let  $AB$  (fig. 323.) be the common intersection of two planes.

Fig. 319.

Fig. 320.

Fig. 321.

Fig. 322.

If two right lines LM, FG be drawn, in these two planes, perpendicular to the line AB, these will form four angles at the point C, which are called the *inclinations* of the two planes, or the angles formed by the two planes.

4. If the line AB (*fig. 324.*) revolves about itself, without changing its place, the line AC, which makes an acute angle with AB, will describe in the revolution a concave surface LAC; and the line AD, which makes an obtuse angle with AB, will describe in the revolution a convex surface MAD.
5. But the line AF (*fig. Defin. 2.*), which makes a right angle with AB, will describe in the revolution a surface which will be neither concave nor convex, but plane: and the line AB will be perpendicular to the plane MLGFPN, because it will make right angles with the lines AM, AL, AG, &c. drawn from the point A in that plane.
6. Two planes are *parallel* when all perpendiculars drawn from one to the other are equal. See *fig. 325.*, wherein AB, CD are equal between the surfaces LM, FG.

Fig. 323.

Fig. 324.

970. PROP. XC. *A perpendicular is the shortest line which can be drawn from any point to a plane.*

From the point B (*fig. 326.*), let the right line BA be drawn perpendicular to the plane DF; any other line, as BC, will be longer than the line BA. Upon the plane draw the right line AC.

Because the line BA is perpendicular to the plane DF, the angle BAC is a right angle. The square of BC is therefore (Prop. 32.) equal to the squares of BA and AC taken together. Consequently the square of BC is greater than the square of BA, and the line BC longer than the line BA.

971. PROP. XCI. *A perpendicular measures the distance of any point from a plane.*

The distance of one point from another is measured by a right line, because it is the shortest line which can be drawn from one point to another. So the distance from a point to a line is measured by a perpendicular, because this line is the shortest which can be drawn from the point to the line. In like manner, the distance from a point to a plane must be measured by a perpendicular drawn from that point to the plane, because this is the shortest line which can be drawn from the point to the plane.

Fig. 325.

Fig. 326.

972. PROP. XCII. *The common intersection of two planes is a right line.*

Let the two planes ALBMA, AFBGA (*fig. 327.*) intersect each other; the line which is common to both is a right line. Draw a right line from the point A to the point B.

Because the right line AB touches the two planes in the points A and B, it will touch them (Defin. 1.) in all other points; this line therefore, is common to the two planes. Wherefore the common intersection of the two planes is a right line.

973. PROP. XCIII. *If three points, not in a right line, are common to two planes, these two planes are one and the same plane.*

Let two planes be supposed to be placed upon one another, in such manner that the three points A, B, C shall be common to the two planes; all their other points will also be common, and the two planes will be one and the same plane. The point D, for example, is common to both planes. Draw the right lines AB, CD.

Fig. 327.

Because the right line AB touches the two planes in the points A and B, it will touch them (Defin. 1.) in every other point; it will therefore touch them in the point F. The point F is therefore common to the two planes.

Again, because the right line CD touches the two planes in the points C and F, it will touch them in the point D; therefore the point D is common to the two planes. The same may be shown concerning every other point. Wherefore the two planes coincide in all points, or are one and the same plane.

Fig. 328.

974. PROP. XCIV. *If a right line be perpendicular to two right lines which cut each other, it will be perpendicular to the plane of these right lines.*

Let the line AB (*fig. 329.*) make right angles with the lines AC, AD, it will be perpendicular to the plane which passes through these lines.

If the line AB were not perpendicular to the FDCG, another plane might be made to pass through the point A, to which the AB would be perpendicular. But this is impossible; for, since the angles BAC, BAD are right angles, this other plane (*Defin. 2.*) must pass through the points C, D; it would therefore (*Prop. 93.*) be the same with the plane FDCG, since these two planes would have three common points A, C, D.

975. *PROP. XCV. From a given point in a plane to raise a perpendicular to that plane.*

Let it be required to raise a perpendicular from the point A (*fig. 330.*) in the plane LM.

Form a rectangle CDFG, divide it into two rectangles, having a common section AB, and place these rectangles upon the plane LM in such a manner that the bases of the two rectangles AC, AG shall be in the plane LM, and form any angle with each other; the line AB shall be perpendicular to the plane LM. The line AB makes right angles with the two lines AC, AG, which, by supposition, are in the plane LM; it is therefore (*Prop. 94.*) perpendicular to the plane LM.

Fig. 330.

976. *PROP. XCVI. Two planes cutting each other at right angles, if a right line be drawn in one of the planes perpendicular to their common intersection, it will be perpendicular to the other plane.*

Let the two planes AFBG, ALBM (*fig. 331.*) cut each other at right angles; if the line LC be perpendicular to their common intersection, it is also perpendicular to the plane AFBG. Draw CG perpendicular to AB.

Because the lines CL, CG are perpendicular to the common intersection AB, the angle LCG (*Defin. 3.*) is the angle of inclination of the two planes. Since the two planes cut each other perpendicularly, the angle of inclination LCG is therefore a right angle.

And because the line LC is perpendicular to the two lines CA, CG in the plane AFBG, it is (*Prop. 94.*) perpendicular to the plane AFBG.

977. *PROP. XCVII. If one plane meet another plane, it makes angles with that other plane, which are together equal to two right angles.*

Let the plane ALBM (*fig. 332.*) meet the plane AFBG; these planes will make with each other two angles, which will together be equal to two right angles. Through any point C draw the lines FG, LM perpendicular to the line AB. The line CL makes with the line FG two angles together equal to two right angles. But these two angles are (*Defin. 3.*) the angles of inclination of the two planes. Therefore the two planes make angles with each other, which are together equal to two right angles.

*COROLLARY.* It may be demonstrated in the same manner that planes which intersect each other have their vertical angles equal, that parallel planes have their alternate angles equal, &c.

978. *PROP. XCVIII. If two planes be parallel to each other, a right line, which is perpendicular to one of the planes, will be also perpendicular to the*

Fig. 331.

Fig. 332.

Let the two planes LM, FG (*fig. 333.*) be parallel. If the line BA be perpendicular to the plane FG, it will also be perpendicular to the plane LM. From any point C in the plane LM draw CD perpendicular to the plane FG, and draw BC, AD.

Because the lines BA, CD are perpendicular to the plane FG, the angles A, D are right angles.

Because the planes LM, FG are parallel, the perpendiculars AB, DC (*Defin. 6.*) are equal; whence it follows that the lines BC, AD are parallel.

The line BA, being at right angles to the line AD, will also (*Prop. 13.*) be at right angles to the parallel line BC. The line BA is therefore perpendicular to the line BC.

In the same manner it may be demonstrated that the line BA is at right angles to all other lines which can be drawn from the point B in the plane LM. Wherefore (*Defin. 2.*) the line BA is perpendicular to the plane LM.

Fig. 333.

## SOLIDS.

979. DEFINITIONS. — 1. A *solid*, as we have before observed, is that which has length, breadth, and thickness.

2. A *polyhedron* is a solid terminated by plane surfaces.

3. A *prism* is a solid terminated by two identical plane bases parallel to each other, and by surfaces which are parallelograms. (Fig. 334.)

4. A *parallelopiped* is a prism the bases of which are parallelograms. (Fig. 335.)

5. A *cube* is a solid terminated by six square surfaces: a die, for example, is a cube. (Fig. 336.)

6. If right lines be raised from every point in the perimeter of any rectilinear figure, and meet in one common point, these lines together with the rectilinear figure inclose a solid which is called a *pyramid*. (Fig. 337.)

7. A *cylinder* is a solid terminated by two bases, which are equal and parallel circles, and by a convex surface; or it is a solid formed by the revolution of a parallelogram about one of its sides. (Fig. 338.)

8. If right lines be raised from every point in the circumference of a circle, and meet in one common point, these lines together with the circle inclose a solid, which is called a *cone*. (Fig. 339.)

9. A semicircle revolving about its diameter forms a solid, which is called a *sphere*. (Fig. 340.)

10. If from the vertex of a solid a perpendicular be let fall upon the opposite plane, this perpendicular is called the *altitude* of the solid. In the pyramids  $ACD$ ,  $Acd$  (fig. 341.),  $AB$ ,  $ab$  are their respective altitudes.

11. Solids are said to be *equal*, if they inclose an equal space: thus a cone and a pyramid are equal solids if the space inclosed within the cone be equal to the space inclosed within the pyramid.

12. *Similar solids* are such as consist of an equal number of physical points disposed in the same manner.

Thus (in the fig. Defin. 10.) the larger pyramid  $ACD$  and the smaller pyramid  $Acd$  are similar solids if every point in the larger pyramid has a point corresponding to it in the smaller pyramid. A hundred musket balls, and the same number of cannon balls, disposed in the same manner, form two similar solids.

980. PROP. XCIX. *The solid content of a cube is equal to the product of one of its sides twice multiplied by itself.*

Let the lines  $AB$ ,  $AD$  (fig. 342.) be equal. Let the line  $AD$ , drawn perpendicular to  $AB$ , be supposed to move through the whole length of  $AB$ ; when it arrives at  $BC$ , and coincides with it, it will have formed the square  $DABC$ , and will have been multiplied by the line  $AB$ .

Next let the line  $AF$  be drawn equal to  $AD$ , and perpendicular to the plane  $DABC$ ; suppose the plane  $DABC$  to move perpendicularly through the whole length of the line  $AF$ ; when it arrives at the plane  $MFLG$ , and coincides with it, it will have formed the cube  $AFLC$ , and will have been multiplied by the line  $AF$ .

Hence it appears, that to form the cube  $AFLC$ , it is necessary, first, to multiply the side  $AD$  by the side  $AB$  equal to  $AD$ ; and then to multiply the product, that is, the square of  $AC$ , by the side  $AF$  equal to  $AD$ ; that is, it is necessary to multiply  $AD$  by  $AD$ , and to multiply the product again by  $AD$ .

981. PROP. C. *Similar solids have their homologous lines proportional.*

Let the two solids  $A$ ,  $a$  (fig. 343.) be similar; and let their homologous lines be  $AB$ ,  $ab$ ,  $BG$ ,  $bg$ ;  $AB$  will be to  $BG$  at  $ab$  to  $bg$ .

Because the solids  $A$ ,  $a$  are similar, every point in the solid  $A$  has a point corresponding to it, and disposed in the same

Fig. 334.

Fig. 335.

Fig. 336.

Fig. 337.

Fig. 338.

Fig. 339.

Fig. 340.

Fig. 341.

Fig. 342.

Fig. 343.

manner, in the solid  $a$ . Thus, if the line  $AB$  is composed of 20 physical points, and the line  $BG$  of 10, the line  $ab$  will be composed of 20 corresponding points, and the line  $bg$  of 10. Now it is evident that 20 is to 10 as 20 is to 10: therefore  $AB$  is to  $BG$  as  $ab$  to  $bg$ .

982. PROP. CI. *Similar solids are equiangular.*

Let the solids (see fig. to preced. Prop.)  $A, a$  be similar; their corresponding angles are equal.

Because the solids  $A, a$  are similar, the surfaces  $BAF, baf$  are composed of an equal number of points disposed in the same manner. These surfaces are therefore similar figures, and consequently (Prop. 88.) equiangular. The angles  $B, A, F$  are therefore equal to the angles  $b, a, f$ . In the same manner it may be demonstrated that the other correspondent angles are equal.

983. PROP. CII. *Solids which have their angles equal and their sides proportional are similar.*

If the solids  $A, a$  (fig. 344.) have their angles equal and their sides proportional, they are similar.

For if the solids  $A, a$  were not similar, another solid might be formed upon the line  $BF$  similar to the solid  $a$ . But this is impossible; for, in order to form this other solid, some angle or some side of the solid  $A$  must be increased or diminished; and then this new solid would not have all its angles equal and all its sides proportional to those of the solid  $a$ , that is (Prop. 100, 101.), would not be similar.

984. PROP. CIII. *Similar solids are to one another as the cubes of their homologous sides.*

Let  $A, a$  (see fig. to preced. Prop.) be two similar solids, the solid  $A$  contains the solid  $a$  as many times as the cube formed upon the side  $BF$  contains the cube formed upon the side  $bf$ .

Because the solid  $A$  is similar to the solid  $a$ , every point in the solid  $A$  has its corresponding point in the solid  $a$ . From whence it follows, that if the side  $BF$  is composed, for example, of 50 points, the side  $bf$  will also be composed of 50 points: and consequently the cubes formed upon the sides  $BF, bf$  will be composed of an equal number of points.

Let it then be supposed that the solid  $A$  is composed of 4000 points, and the cube of the side  $BF$  of 5000 points; the solid  $A$  must be composed of 4000 points, and the cube of the side  $bf$  of 5000 points. Now it is evident that 4000 is to 5000 as 4000 to 5000. Wherefore the solid  $A$  is to the cube of  $BF$  as the solid  $a$  is to the cube of  $bf$ ; and, alternately, the solid  $A$  is to the solid  $a$  as the cube of  $BF$  to the cube of  $bf$ .

COROLLARY. It may be demonstrated in the same manner that the spheres  $A, a$  (fig. 345.), which are similar solids, are to one another as the cubes of their radii  $AB, ab$ .

985. PROP. CIV. *The solid content of a perpendicular prism is equal to the product of its base and height.*

The solid content of the perpendicular prism  $ABCD$  (fig. 346.) is equal to the product of its base  $AD$ , and height  $AD$ .

If the lower base  $AD$  be supposed to move perpendicularly along the height  $AB$  till it coincides with the upper base  $BC$ , it will have formed the prism  $ABCD$ . Now the base  $AD$  will have been repeated as many times as there are physical points in the height  $AB$ . Therefore the solid content of the prism  $ABCD$  is equal to the product of the base multiplied by the height.

COROLLARY. In the same manner it may be demonstrated that the solid content of the perpendicular cylinder  $ABCD$  is equal to the product of its base  $AD$  and height  $AB$ .

986. PROP. CV. *The solid content of an inclined prism is equal to the product of its base and height.*

Let the inclined prism be  $CP$  (fig. 347.), it is equal to the product of its base  $RP$  and its height  $CD$ .

Conceive the base  $NB$  of the perpendicular prism  $NA$ , and the base  $RP$  of the inclined prism  $PC$ , to move on in the same time parallel to themselves; when they have reached the points  $A$  and  $C$ , each of them will have been taken over again the same number of times. But the base  $NB$  will have been taken over again (Prop. 104.) as many times as there are physical points in the height  $CD$ . The base  $RP$  will therefore have been taken over again as many times as there are physical points in  $CD$ . Consequently the solid content of the inclined prism  $CP$  is equal to the product of its base  $RP$  and the height  $CD$ .

Fig. 344.

Fig. 345

Fig. 346.

Fig. 347.

987. PROP. CVI. *In a pyramid, a section parallel to the base is similar to the base.*

Let the section  $cd$  be parallel to the base  $CD$  (fig. 348.); this section is a figure similar to the base. Draw  $AB$  perpendicular to the base  $CD$ ; draw also  $BC$ ,  $bc$ ,  $BE$ ,  $be$ .

Because the planes  $cd$   $CD$  are parallel;  $AB$ , being perpendicular to the plane  $CD$ , will also (Prop. 98.) be perpendicular to the plane  $cd$ : whence the triangles  $Abc$ ,  $ABC$ , having the angles  $b$ ,  $B$  right angles, and the angle  $A$  common, are equiangular. Therefore (Prop. 61.)  $Ab$  is to  $AB$  as  $bc$  to  $BC$ , and as  $Ac$  to  $AC$ .

In like manner it may be proved that  $Ab$  is to  $AB$  as  $be$  to  $BE$ , and as  $Ae$  to  $AE$ . Consequently if  $Ab$  be one third part of  $AB$ ,  $bc$  will be one third part of  $BC$ ,  $be$  the same of  $BE$ ,  $Ac$  of  $AC$ , and  $Ae$  of  $AE$ .

Again, in the two triangles  $cAe$ ,  $CAE$ , there are about the angle  $A$ , common to both, two sides proportional; they are therefore (Prop. 63.) equiangular, and consequently (Prop. 61.) have their other sides proportional. Therefore  $ce$  will be one third part of  $CE$ .

The two triangles  $cbe$   $CBE$ , having their sides proportional, are therefore (Prop. 89.) similar. The same may be demonstrated concerning all the other triangles which form the planes  $cd$ ,  $CD$ . Therefore the section  $cd$  is similar to the base  $CD$ .

REMARK. If the perpendicular  $AB$  fall out of the base; by drawing lines from the points  $b$ ,  $B$ , it may be demonstrated in the same manner that the section is similar to the base.

988. PROP. CVII. *In a pyramid, sections parallel to the base are to one another as the squares of their heights.*

Let  $CD$   $cd$  (fig. 349.) be parallel sections. From the vertex  $A$  draw a perpendicular  $AB$  to the plane  $CD$ : the plane  $cd$  is to the plane  $CD$  as the square of the height  $Ab$  is to the square of the height  $AB$ . Draw  $BC$ ,  $bc$ .

The line  $AB$ , being perpendicular to the plane  $CD$ , will also (Prop. 98.) be perpendicular to the parallel plane  $cd$ : whence the angle  $Abc$  is a right angle, and also the angle  $ABC$ . Moreover, the angle at  $A$  is common to the two triangles  $Abc$ ,  $ABC$ ; these two triangles, therefore, are equiangular. Therefore (Prop. 61.) the side  $cb$  is to the side  $CB$  as the side  $Ab$  is to the side  $AB$ ; and consequently the square of  $cb$  is to the square of  $CB$  as the square of  $Ab$  is to the square of  $AB$ .

The planes  $cd$ ,  $CD$ , being (Prop. 106.) similar figures, are to one another (Prop. 82.) as the squares of the homologous lines  $cb$ ,  $CB$ ; they are therefore also as the squares of the heights  $Ab$ ,  $AB$ .

COROLLARY. In the same manner it may be demonstrated that in a cone the sections parallel to the base are to one another as the squares of the heights or perpendicular distances from the vertex.

989. PROP. CVIII. *Pyramids of the same height are to one another as their bases.*

Let  $A$ ,  $F$  (fig. 350.) be two pyramids. If the perpendicular  $AB$  be equal to the perpendicular  $FG$ , the pyramid  $A$  is to the pyramid  $F$  as the base  $CD$  to the base  $LM$ . Supposing, for example, the base  $CD$  to be triple of the base  $LM$ , the pyramid  $A$  will be triple of the pyramid  $F$ .

Two sections  $cd$ ,  $lm$ , being taken at equal heights  $Ab$ ,  $Fg$ , the section  $cd$  is (Prop. 107.) to the base  $CD$  as the square of the height  $Ab$  to the square of the height  $AB$ ; and the section  $lm$  is to the base  $LM$  as the square of the height  $Fg$  to the square of the height  $FG$ . And because the heights are equal,  $AB$  to  $FG$ , and  $Ab$  to  $Fg$ , the section  $cd$  is to the base  $CD$  as the section  $lm$  to the base  $LM$ ; and, alternately, the section  $cd$  is to the section  $lm$  as the base  $CD$  is to the base  $LM$ . But the base  $CD$  is triple of the base  $LM$ , therefore the section  $cd$  is also triple of the section  $lm$ .

Because the heights  $AF$ ,  $FG$  are equal, it is manifest that the two pyramids are composed of an equal number of physical surfaces placed one upon another. Now it may be demonstrated in the same manner that every surface or section of the pyramid  $A$  is triple of the corresponding surface or section of the pyramid  $F$ . Therefore the whole pyramid  $A$  is triple of the whole pyramid  $F$ .

COROLLARY. Pyramids of the same height and equal bases are equal, since they are to one another as their bases.

990. PROP. CIX. *A pyramid whose base is that of a cube and whose vertex is at the centre of the cube is equal to a third part of the product of its height and base.*

Fig. 348.

Fig. 349.

Fig. 350.

Let the cube AM and the pyramid C (*fig. 351.*) have the same base AD, and let the vertex of the pyramid be at the centre of the cube C; this pyramid is equal to a third part of the product of its height and base.

Conceive right lines drawn from the centre of the cube to its eight angles A, B, D, F, N, G, L, M, the cube will be divided into six equal pyramids, each of which has one surface of the cube for its base, and half the height of the cube for its height; for example, the pyramid CABDF.

Three of these pyramids will therefore be equal to half the cube. Now the solid content of half the cube is (Prop. 99.) equal to the product of the base and half the height. Each pyramid, therefore, will be equal to one third part of the product of the base, and half the height of the cube; that is, the whole height of the pyramid.

991. *PROP. CX. The solid content of a pyramid is equal to a third part of the product of its height and base.*

Let RPS (*fig. 352.*) be a pyramid, its solid content is equal to a third part of the product of its height and its base RS.

Form a cube the height of which BL is double of the height of the pyramid RPS. A pyramid the base of which is that of this cube and the vertex of which is C, the centre of the cube, will be equal to a third part of the product of its base and height.

The pyramids C and P have the same height; they are therefore (Corol. to Prop. 108.) to one another as their bases. If the base AFDB is double of the base RS, the pyramid C will therefore be double of the pyramid P.

But the pyramid C is equal to a third part of the product of its height and base. The pyramid P will therefore be equal to a third part of the product of the same height, and half the base AFDB, or, which is the same thing, the whole base RS.

992. *PROP. CXI. The solid content of a cone is equal to the third part of the product of its height and base.*

For the base of a cone may be considered as a polygon composed of exceedingly small sides, and consequently the cone may be considered as a pyramid having a great number of exceedingly small surfaces; whence its solid contents will be equal (Prop. 110.) to one third part of the product of its height and base.

993. *PROP. CXII. The solid content of a cone is a third part of the solid content of a cylinder described about it.*

Let the cone BAC and the cylinder BDFC (*fig. 353.*) have the same height and base, the cone is a third part of the cylinder.

For the cylinder is equal to the product of its height and base, and the cone is equal to a third part of this product. Therefore the cone is a third part of the cylinder.

994. *PROP. CXIII. The solid content of a sphere is equal to a third part of the product of its radius and surface.*

Two points not being sufficient to make a curve line, three points will not be sufficient to make a curve surface. If, therefore, all the physical points which compose the surface of the sphere C (*fig. 354.*) be taken three by three, the whole surface will be divided into exceedingly small plane surfaces; and radii being drawn to each of these points, the sphere will be divided into small pyramids, which have their vertex at the centre, and have plane bases.

The solid contents of all these small pyramids will be equal (Prop. 110.) to a third part of the product of the height and bases. Therefore the solid content of the whole sphere will be equal to a third part of the product of the height and all the bases, that is, of its radius and surface.

995. *PROP. CXIV. The surface of a sphere is equal to four of its great circles.*

If a plane bisect a sphere, the section will pass through the centre, and it is called a great circle of the sphere.

Let ABCD (*fig. 355.*) be a square; describe the fourth part of the circumference of a circle BLD; draw the diagonal AC, the right line FM, parallel to AD, and the right line AL.

In the triangle ABC, on account of the equal sides AB, BC, the angles A and C are (Prop. 4.) equal; therefore, since the angle B is a right angle, the angles A and C are each half a right angle. Again, in the triangle AFG, because the angle F is a right angle, and the angle A half a right angle, the angle G is also half a right angle; therefore (Prop. 26.) AF is equal to FG.

Fig. 351.

Fig. 352.

Fig. 353.

Fig. 354.

Fig. 355.

The radius AL is equal to the radius AD : but AD is equal to FM ; therefore AL is equal to FM.

In the rectangular triangle AFL the square of the hypotenuse AL is equal (Prop. 32.) to the two squares of AF and FL taken together. Instead of AL put its equal FM, and instead of AF put its equal FG ; and the square of FM will be equal to the two squares of FG and FL taken together.

Conceive the square ABCD to revolve about the line AB. In the revolution the square will describe a cylinder, the quadrant a hemisphere, and the triangle ABC an inverted cone the vertex whereof will be in A. Also the line FM will form a circular section of a cylinder, the line FL will form a circular section of a hemisphere, and the line FG a circular section of a cone.

These circular sections, or circles, are to each other (Prop. 83.) as the squares of their radii ; therefore, since the square of the radius FM is equal to the squares of the radii FL and FG, the circular section of the cylinder will be equal to the circular sections of the hemisphere and cone.

In the same manner it may be demonstrated that all the other sections or circular surfaces whereof the cylinder is composed are equal to the corresponding sections or surfaces of the hemisphere and cone. Therefore the cylinder is equal to the hemisphere and cone taken together : but the cone (Prop. 112.) is equal to a third part of the cylinder : the hemisphere is therefore equal to the remaining two thirds of the cylinder ; and consequently the hemisphere is double of the cone. The cone BSC (fig. 356.) is (Prop. 111.) equal to a third part of the product of the radius and base BC, which is a great circle of the sphere : the hemisphere ALD is therefore equal to a third part of the product of the radius and two of its great circles ; and consequently the whole sphere is equal to a third part of the product of the radius and four of its great circles.

Lastly, since the sphere is equal (Prop. 113.) to a third part of the product of the radius and surface of the sphere, and also to a third part of the product of the radius and four of its great circles, the surface of the sphere is equal to four of its great circles.

Fig. 356.

## SECT. III.

## PRACTICAL GEOMETRY.

996. Practical Geometry is the art of accurately delineating on a plane surface any plane figure. It is the most simple species of geometrical drawing, and the most generally useful ; for the surfaces of buildings and other objects are more frequently plane than curved, and they must be drawn with truth, and of the required proportions, before they can be properly executed, unless in cases where the extreme simplicity of the form renders it improbable that mistakes should arise. It has been defined as the art which directs the mechanical processes for finding the position of points, lines, surfaces, and planes, with the description of such figures on diagrams as can be intelligibly understood by definition, according to given dimensions and positions of lines, points, &c.

No part of a building or drawing can be laid down or understood without the assistance of practical geometry, nor can any mechanical employment in the building department be conducted without some assistance from this branch of the science. Cases frequently occur requiring a knowledge of very complex problems, as in masonry, carpentry, and joinery ; but these will be given in other parts of this work.

The demonstration of most of the following problems will be found in the preceding section ; we therefore refer the reader back to it for definitions, and for the proof of those enunciations which will follow.

## PROBLEMS.

997. PROBLEM I. To bisect a line AB ; that is, to divide it into two equal parts.

From the two centres A and B (fig. 357.) with any equal radii describe arcs of circles intersecting each other in C and D, and draw the line CD. This will bisect the given line in the point E.

998. PROB. II. To bisect an angle BAC.

From the centre A (fig. 358.) with any radius describe an arc cutting off the equal lines AD, AE ; and from the two centres D, E, with the same radius describe arcs intersecting in F, then draw AF, and it will bisect the angle A, as required.

999. PROB. III. At a given point C in a line AB to erect a perpendicular.

From the given point C (*fig. 359.*) with any radius cut off any equal parts CD, CE of the given line; and from the two centres D and E with any one radius describe arcs intersecting in F. Then join CF, and it will be the perpendicular required.

Otherwise — When the given point C is near the end of the line.

From any point D (*fig. 360.*) assumed above the line as a centre, through the given point C describe a circle cutting the given line at E, and through E and the centre D draw the diameter EDF; then join CF, and it will be the perpendicular required.

Fig. 357.

Fig. 358.

Fig. 359.

1000. PROB. IV. *From a given point A to let fall a perpendicular on a line BC.*

From the given point A (*fig. 361.*) as a centre with any convenient radius describe an arc cutting the given line at two points D and E; and from the two centres D and E with any radius describe two arcs intersecting at F; then draw AGF, and it will be the perpendicular to BC required.

Otherwise — When the given point is nearly opposite the end of the line.

From any point D in the given line BC (*fig. 362.*) as a centre, describe the arc of a circle through the given point A cutting BC in E; and from the centre E with the radius EA describe another arc cutting the former in F; then draw AGF, which will be the perpendicular to BC required.

Fig. 360.

Fig. 361.

1001. PROB. V. *At a given point A, in a line AB, to make an angle equal to a given angle C.*

From the centres A and C (*fig. 363.*) with any radius describe the arcs DE, FG; then with F as a centre, and radius DE, describe an arc cutting FG in G; through G draw the line AG, which will form the angle required.

Fig. 362.

Fig. 363.

1002. PROB. VI. *Through a given point C to draw a line parallel to a given line AB.*

#### Case I.

Take any point *d* in AB (*fig. 364.*); upon *d* and C, with the distance *Cd*, describe two arcs, *eC* and *df*, cutting AB in *e* and *d*. Make *df* equal to *eC*; and through *Cf* draw *Cf*, and it will be the line required.

Fig. 364.

#### Case II.

When the parallel is to be drawn at a given distance from AB.

From any two points *c* and *d* in the line AB, with a radius equal to the given distance describe the arcs *e* and *f*; draw the line CB to touch those arcs without cutting them, and it will be parallel to AB, as required.

1003. PROB. VII. *To divide a line AB into any proposed number of equal parts.*

Draw any other line AC (*fig. 365.*), forming any angle with the given line AB; on the latter set off as many of any equal parts AD, DE, EF, FC as those into which the line AB is to be divided; join BC, and parallel thereto draw the other lines FG, EH, DI; then these will divide AB, as required.

1004. PROB. VIII. *To find a third proportional to two other lines AB, AC.*

Let the two given lines be placed to form any angle at A (*fig. 366.*), and in AB take AD equal to AC; join BC, and draw DE parallel to it; then AE will be the third proportional sought.

Fig. 365.

1005. PROB. IX. To find a fourth proportional to three lines AB, AC, AD.

Let two of the lines AB, AC (fig. 367.), be so placed as to form any angle at A, and set out AD or AB; join BC, and parallel to it draw DE; then AE will be the fourth proportional required.

1006. PROB. X. To find a mean proportional between two lines AB, BC.

Place AB, BC (fig. 368.) joined together in one straight line AC, which bisect in the point O; then with the centre O and radius OA or OC describe the semicircle ADC, to meet which erect the perpendicular BD, which will be the mean proportional between AB and BC sought.

Fig. 368.

Fig. 369.

Fig. 370.

1007. PROB. XI. To find the centre of a circle.

Draw any chord AB (fig. 369.), and bisect perpendicularly with the line CD, which bisected in O will be the centre required.

1008. PROB. XII. To describe the circumference of a circle through three points A, B, C. From the middle point B (fig. 370.) draw the chords BA, BC to the two other points, and bisect these chords perpendicularly by lines meeting in O, which will be the centre; from the centre O, with the distance of any one of the points, as OA, describe a circle, and it will pass through the two other points B, C, as required.

1009. PROB. XIII. To draw a tangent to a circle through a given point A.

When the given point A (fig. 371.) is in the circumference of the circle, join A and the centre O, and perpendicular thereto draw BAC, which will be the tangent required.

If the given point A (fig. 372.) be out of the circle, draw AO to the centre O, on which, as a diameter, describe a semicircle cutting the given circumference in D, through which draw BADC, which will be the tangent required.

Fig. 371.

Fig. 372.

1010. PROB. XIV. To draw an equilateral triangle on a given line AB.

From the centres A and B (fig. 373.) with the distance AB describe arcs intersecting in C; draw AC, BC, and ABC will be the equilateral triangle.

Fig. 373.

1011. PROB. XV. To make a triangle with three given lines AB, AC, BC.

With the centre A and distance AC (fig. 374.) describe an arc; with the centre B and distance BC describe another arc cutting the former in C; draw AC, BC, and ABC will be the triangle required.

Fig. 374.

1012. PROB. XVI. To make a square on a given line AB.

Raise AD, BC (fig. 375.) each perpendicular and equal to AB, and join DC; then ABCD will be the square sought.

Fig. 375.

1013. PROB. XVII. To inscribe a circle in a given triangle ABC.

Bisect the angles at A and B with the two lines AD, BD (fig. 376.); from the intersection D, which will be the centre of the circle, draw the perpendiculars DE, DF, DG, and they will be the radii of the circle required.

Fig. 376.

1014. PROB. XVIII. To describe a circle about a given triangle ABC.

Bisect any two sides with two of the perpendiculars DE, DF, DG (*fig. 377.*), and D will be the centre of the circle.

1015. PROB. XIX. *To inscribe an equilateral triangle in a given circle.*

Through the centre C draw any diameter AB (*fig. 378.*); from the point B as a centre, with the radius BC of the given circle, describe an arc DCE; join AD, AE, DE, and ADE is the equilateral triangle sought.

1016. PROB. XX. *To inscribe a square in a given circle.*

Draw two diameters AC, BD (*fig. 379.*) crossing at right angles in the centre E; then join the four extremities A, B, C, D with right lines, and these will form the inscribed square ABCD.

1017. PROB. XXI. *To describe a square about a given circle.*

Draw two diameters AC, BD crossing at right angles in the centre E (*fig. 380.*); then through the four extremities of these draw FG, IH parallel to AC, and FI, GH parallel to BD, and they will form the square FGHI.

1018. PROB. XXII. *To inscribe a circle in a given square.*

Bisect the two sides FG, FI in the points A and B (see *fig. 380.*); then through these two points draw AC parallel to FG or IH, and BD parallel to FI or GH. Then the point of intersection E will be the centre, and the four lines EA, EB, EC, ED radii of the inscribed circle.

1019. PROB. XXIII. *To cut a given line in extreme and mean ratio.*

Let AB be the given line to be divided in extreme and mean ratio (*fig. 381.*); that is, so that the whole line may be to the greater part as the greater part is to the less part.

Draw BC perpendicular to AB, and equal to half AB; join AC, and with the centre C and distance CB describe the circle BD; then with the centre A and distance AD describe the arc DE. Then AB will be divided in E in extreme and mean ratio, or so that AB is to AE as AE is to EB.

1020. PROB. XXIV. *To inscribe an isosceles triangle in a given circle that shall have each of the angles at the base double the angle at the vertex.*

Draw any diameter AB of the given circle (*fig. 382.*), and divide the radius CB in the point D in extreme and mean ratio (by the last problem); from the point B apply the chords BE, BF, each equal to the greater part CD; then join AE, AF, EE; and AEF will be triangle required.

1021. PROB. XXV. *To inscribe a regular pentagon in a given circle.*

Inscribe the isosceles triangle AB (*fig. 383.*) having each of the angles ABC, ACB double the angle BAC (Prob. 24.); then bisect the two arcs ADB, AEC, in the points D, E; and draw the chords AD, DB, AE, EC; then ADBCE will be the inscribed equilateral triangle required.

1022. PROB. XXVI. *To inscribe a regular hexagon in a circle.*

Apply the radius of the given circle AO as a chord (*fig. 384.*) quite round the circumference, and it will form the points thereon of the regular hexagon ABCDEF.

1023. PROB. XXVII. *To describe a regular pentagon or hexagon about a circle.*

In the given circle inscribe a regular polygon of the same name or number of sides as ABCDE (*fig. 385.*) by one of the foregoing problems; then to all its angular points draw (Prob. 13.) tangents, and these will by their intersections form the circumscribing polygon required.

Fig. 377.

Fig. 378.

Fig. 379.

Fig. 380.

Fig. 381.

Fig. 382.

Fig. 383.

Fig. 384.

Fig. 385.

Fig. 386.

1024. PROB. XXVIII. *To inscribe a circle in a regular polygon.*

Bisect any two sides of the polygon by the perpendiculars  $GO$ ,  $FO$  (*fig. 386.*), and their intersection  $O$  will be the centre of the inscribed circle, and  $OG$  or  $OF$  will be the radius.

1025. PROB. XXIX. *To describe a circle about a regular polygon.*

Bisect any two of the angles  $C$  and  $D$  with the lines  $CO$ ,  $DO$  (*fig. 387.*), then their intersection  $O$  will be the centre of the circumscribing circle; and  $OC$  or  $OD$  will be the radius.

1026. PROB. XXX. *To make a triangle equal to a given quadrilateral ABCD.*

Draw the diagonal  $AC$  (*fig. 388.*), and parallel to it  $DE$ , meeting  $BA$  produced at  $E$ , and join  $CE$ ; then will the triangle  $CEB$  be equal to the given quadrilateral  $ABCD$ .

Fig. 387.

Fig. 388.

1027. PROB. XXXI. *To make a triangle equal to a given pentagon ABCDE.*

Draw  $DA$  and  $DB$ , and also  $EF$ ,  $CG$  parallel to them (*fig. 389.*), meeting  $AB$  produced at  $F$  and  $G$ ; then draw  $DF$  and  $DG$ , so shall the triangle  $DFG$  be equal to the given pentagon  $ABCDE$ .

Fig. 389.

Fig. 390.

1028. PROB. XXXII. *To make a rectangle equal to a given triangle ABC.*

Bisect the base  $AB$  in  $D$  (*fig. 390.*), then raise  $DE$  and  $BF$  perpendicular to  $AB$ , and meeting  $CF$  parallel to  $AB$  at  $E$  and  $F$ . Then  $DF$  will be the rectangle equal to the given triangle  $ABC$ .

1029. PROB. XXXIII. *To make a square equal to a given rectangle ABCD.*

Produce one side  $AB$  till  $BE$  be equal to the other side  $BC$  (*fig. 391.*). On  $AE$  as a diameter describe a circle meeting  $BC$  produced at  $F$ , then will  $BF$  be the side of the square  $BFGH$  equal to the given rectangle  $BD$ , as required.

Fig. 391.

Fig. 392.

1030. PROB. XXXIV. *To draw a catenary.*

A catenary being a curve into which a perfectly flexible cord or chain will arrange itself when suspended by its two extremities, it may thus be described. Let  $AB$  (*fig. 392.*) be a given line from two points  $c, d$ , whereof the curve is to fall, and let  $C$  be the lowest point in the curve. From two pins inserted at the points  $c$  and  $d$  suspend a fine cord or chain, lengthening it till the lowest point of the crown touches  $C$ , then a pencil tracing its line on the paper; the curve thus formed will be the catenary required.

1031. PROB. XXXV. *To draw a cycloid.*

If the circumference of a circle be rolled along a right line  $AB$  (*fig. 393.*) until any point  $b$  in the circumference which was in contact with the line come again in contact with it, the point  $b$  will describe a curve called a cycloid. Let the circle be  $BC$ , and the semi-base be  $AB$ , which must be equal to the semi-circumference of the circle. Draw any chords  $Cb$ ,  $Cb$ , and parallel to  $AB$  draw the horizontal lines  $ab$ ,  $ab$ , making them respectively equal to the length of the arcs cut off by the chords. Then through the points  $a, a$ , so obtained, draw a curve line, and it will be the cycloid required.

Fig. 393.

1032. PROB. XXXVI. *To draw a diagonal scale.*

Let it be of feet, tenths and hundredth parts of a foot. Set off on  $AB$  (*fig. 394.*) as many times as necessary, the number of feet by equal distances. Divide  $AG$  into ten equal parts. On  $AB$  raise the perpendiculars  $BD$ ,  $GG$ , and  $AC$ , and set off on  $AC$  ten equal divisions of any convenient length, through which draw horizontal lines. Then, from the point  $G$  in  $DC$  to the first tenth part from  $G$  to  $A$  in  $BA$  draw a diagonal, and parallel thereto the other diagonals required. The intersections of these diagonals with the horizontal lines give hundredth parts of a foot, inasmuch as each tenth is divided by the diagonals into ten equal parts in descending.

Fig. 394.

## SECT. IV.

## PLANE TRIGONOMETRY.

1033. Plane Trigonometry is that branch of mathematics whose object is the investigation and calculation of the sides and angles of plane triangles. It is of the greatest importance to the architect in almost every part of his practice; but the elements will be sufficient for his use, without pursuing it into those more abstruse subdivisions which are essential in the more abstract relations which connect it with geodisic operations.

1034. We have already observed that every circle is supposed to be divided into 360 equal parts, called degrees, and that each degree is subdivided into 60 minutes, these minutes each into 60 seconds, and so on. Hence a semicircle contains 180 degrees, and a quadrant 90 degrees.

1035. The measure of an angle is that arc of a circle contained between those two lines which form the angle, the angular point being the centre, and such angle is estimated by the number of degrees contained in the arc. Thus, a right angle whose measure is a quadrant or quarter of the circle is one of 90 degrees (Prop. 22. Geometry); and the sum of the three angles of every triangle, or two right angles, is equal to 180 degrees. Hence in a right-angled triangle, one of the acute angles being taken from 90 degrees, the other acute angle is known; and the sum of two angles in a triangle taken from 180 degrees leaves the third angle; or either angle taken from 180 degrees leaves the sum of the other two angles.

1036. It is usual to mark the figure which denotes degrees with a small  $^{\circ}$ : thus,  $60^{\circ}$  means 60 degrees; minutes are marked thus  $'$ : hence,  $45'$  means 45 minutes; seconds are marked thus  $''$ ,  $49''$  meaning 49 seconds; and an additional comma is superadded for thirds, and so on. Thus,  $58^{\circ} 14' 25''$  is read 58 degrees, 14 minutes, 25 seconds.

1037. The complement of an arc is the quantity it wants of 90 degrees. Thus, AD (fig. 395.) being a quadrant, BD is the complement of the arc AB, and, reciprocally, AB is the complement of BD. Hence, if an arc AB contain 50 degrees, its complement BD will be 40.

1038. The supplement of an arc is that which it wants of 180 degrees. Thus, ADE being a semicircle, BDE is the supplement of the arc AB, which arc, reciprocally, is the supplement of BDE. Thus, if AB be an arc of 50 degrees, then its supplement BDE will be 130 degrees.

1039. The line drawn from one extremity of an arc perpendicular to a diameter passing through its other extremity is called a *sine* or *right sine*. Thus, BF is the sine of the arc AB, or of the arc BDE. Hence the sine (BF) is half the chord (BG) of the double arc (BAG).

1040. That part of the diameter intercepted between the arc and its sine is called the *versed sine* of an arc. Thus, AF is the versed sine of the arc AB, and EF the versed sine of the arc EDB.

1041. The *tangent* of an arc is a line which touches one end of the arc, continued from thence to meet a line drawn from the centre, through the other extremity, which last line is called the *secant* of the arc. Thus, AH is the tangent and CH the secant of the arc AB. So EI is the tangent and CI the secant of the supplemental arc BDE. The latter tangent and secant are equal to the former; but, from being drawn in a direction opposite or contrary to the former, they are denominated *negative*.

1042. The *cosine* of an arc is the right sine of the complement of that arc. Thus BF, the sine of AB, is the cosine of BD.

1043. The *cotangent* of an arc is the tangent of that arc's complement. Thus AH, which is the tangent of AB, is the cotangent of BD.

1044. The *cosecant* of an arc is the secant of its complement. Thus CH, which is the secant of AB, is the cosecant of BD.

1045. From the above definitions follow some remarkable properties.

I. That an arc and its supplement have the same sine, tangent, and secant; but the two latter, that is, the tangent and the secant, are accounted negative when the arc exceeds a quadrant, or 90 degrees. II. When the arc is 0, or nothing; but the secant then becomes the radius CA, which is the least it can be. As the arc increases from 0, the sines, tangents, and secants all increase, till the arc becomes a whole quadrant AD, and then the sine is the greatest it can be, being equal to the radius of the circle; under which circumstance the tangent and secant are infinite. III. In every arc AB, the versed sine AF, and the cosine BK or CF, are together equal to the radius of the circle. The radius CA, the tangent AH, and the secant CH, form a right-angled triangle CAH. Again, the radius, sine, and cosine form another right-angled triangle CBF or CBK. So also the radius,

Fig. 395.

cotangent, and cosecant form a right-angled triangle CDL. All these right-angled triangles are similar to each other.

1046. The sine, tangent, or secant of an angle is the sine, tangent, or secant of the arc by which the angle is measured, or of the degrees, &c. in the same arc or angle. The method of constructing the scales of chords, sines, tangents, and secants engraved on mathematical instruments is shown in the annexed figure.

1047. A trigonometrical canon (*fig. 396.*) is a table wherein is given the length of the sine, tangent, and secant to every degree and minute of the quadrant, compared with the radius, which is expressed by unity or 1 with any number of ciphers. The logarithms, moreover, of these sines, tangents, and secants, are tabulated, so that trigonometrical calculations are performed by only addition and subtraction. (See 632. *et seq.*) Tables of this sort are published separately, and we suppose the reader to be provided with such.

1048. PROBLEM I. To compute the natural sine and cosine of a given arc.

The semiperiphery of a circle whose radius is 1 is known to be  $3.141592653589793$ , &c.: we have then the following proportion:—

As the number of degrees or minutes in the semicircle  
Is to the degrees or minutes in the proposed arc,  
So is  $3.14159265$ , &c. to the length of the said arc.

Now the length of the arc being denoted by the letter  $a$ , and its sine and cosine by  $s$  and  $c$ , these two will be expressed by the two following series, viz. —

$$\begin{aligned} s &= a - \frac{a^3}{2 \cdot 3} + \frac{a^5}{2 \cdot 3 \cdot 4 \cdot 5} - \frac{a^7}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \cdot 7} + \&c. \\ &= a - \frac{a^3}{6} + \frac{a^5}{120} - \frac{a^7}{5040} + \&c. \\ c &= 1 - \frac{a^2}{2} + \frac{a^4}{2 \cdot 3 \cdot 4} - \frac{a^6}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} + \&c. \\ &= 1 - \frac{a^2}{2} + \frac{a^4}{24} - \frac{a^6}{720} + \&c. \end{aligned}$$

Example 1. Let it be required to find the sine and cosine of one minute. The number of minutes in 180 degrees being 10800, it will be, first, as  $10800 : 1 :: 3.14159265$ , &c. :  $.000290888208665$  = the length of an arc of one minute. Hence, in this case,—

$$a = .0002908882$$

$$\text{and } \frac{1}{2}a^2 = .00000000004$$

The difference is  $s = .0002908882$ , the sine of one minute.

Also from 1.

$$\text{take } \frac{1}{2}a^2 = 0.0000000423079, \&c.$$

$$\text{leaves } c = .9999999577, \text{ the cosine of one minute.}$$

Example 2. For the sine and cosine of 5 degrees:—

Here  $180^\circ : 5^\circ :: 3.14159265$ , &c. :  $.08726646 = a$ , the length of 5 degrees.

$$\text{Hence } a = .08726646$$

$$-\frac{1}{2}a^2 = .00011076$$

$$+\frac{1}{24}a^4 = .00000004$$

These collected give  $s = .08715574$ , the sine of 5 degrees.

And for the cosine  $1 = 1$

$$-\frac{1}{2}a^2 = .00380771$$

$$+\frac{1}{24}a^4 = .00000241$$

These collected give  $c = .99619470$ , the cosine of 5 degrees.

In the same way we find the sines and cosines of other arcs may be computed. The greater the arc the slower the series will converge; so that more terms must be taken to make the calculation exact. Having, however, the sine, the cosine may be found from it by the property of the right-angled triangle CBF, viz. the cosine  $CF = \sqrt{CB^2 - BF^2}$ , or  $c = \sqrt{1 - s^2}$ . There are other methods of constructing tables, but we think it unnecessary to mention them; our sole object being here merely to give a notion of the mode by which such tables are formed.

Fig. 396.

1049. PROB. II. *To compute the tangents and secants.*

Having, by the foregoing problem, found the sines and cosines, the tangents and secants are easily found from the principles of similar triangles. In the arc AB (*fig. 395.*), where BF is the sine, CF or BK the cosine, AH the tangent, CH the secant, DL the cotangent, and CL the cosecant, the radius being CA or CB or CD; the three similar triangles CFB, CAH, CDL, give the following proportions:—

- I.  $CF : FB :: CA : AH$ , by which we find that the tangent is a fourth proportional to the cosine, sine, and radius.
- II.  $CF : CB :: CA : CH$ , by which we find that the secant is a third proportional to the cosine and radius.
- III.  $BF : FC :: CD : DL$ , by which we find that the cotangent is a fourth proportional to the sine, cosine, and radius.
- IV.  $BF : BC :: CD : CL$ , by which we find that the cosecant is a third proportional to the sine and radius.

Observation 1. There are therefore three methods of resolving triangles, or the cases of trigonometry; viz. geometrical construction, arithmetical computation, and instrumental operation. The method of carrying out the first and the last does not need explanation: the method is obvious. The second method, from its superior accuracy in practice, is that whereof we propose to treat in this place.

Observation 2. Every triangle has six parts, viz. three sides and three angles. And in all cases of trigonometry, three parts must be given to find the other three. And of the three parts so given, one at least must be a side; because, with the same angles, the sides may be greater or less in any proportion.

Observation 3. All the cases in trigonometry are comprised in three varieties only; viz.

- 1st. When a side and its opposite angle are given.
- 2d. When two sides and the contained angle are given.
- 3d. When the three sides are given.

More than these three varieties there cannot possibly be; and for each of them we shall give a separate theorem.

1050. THEOREM I. *When a side and its opposite angle are two of the given parts.*

Then—the sides of the triangle have the same proportion to each other as the sines of their opposite angles have. That is,

As any one side  
Is to the sine of its opposite angle,  
So is any other side  
To the sine of its opposite angle.

For let ABC (*fig. 397.*) be the proposed triangle, having AB the greatest side, and BC the least. Take AD as a radius equal to BC, and let fall the perpendiculars DE, CF, which will evidently be the sines of the angles A and B, to the radius AD or BC. Now the triangles ADE, ACF are equiangular; they therefore have their like sides proportional, namely,  $AC : CF :: AD$  or  $BC : DE$ , that is, the sine AC is to the sine of its opposite angle B as the side BC is to the sine of its opposite angle A.

Fig. 397.

Note 1. In practice, when an angle is sought, the proportion is to be begun with a side opposite a given angle; and to find a side, we must begin with the angle opposite the given side.

Note 2. By the above rule, an angle, when found, is ambiguous; that is, it is not certain whether it be acute or obtuse, unless it come out a right angle, or its magnitude be such as to remove the ambiguity; inasmuch as the sine answers to two angles, which are supplements to each other; and hence the geometrical construction forms two triangles with the same parts, as in an example which will follow: and if there be no restriction or limitation included in the question, either result may be adopted. The degrees in a table answering to the sine is the acute angle; but if the angle be obtuse, the degrees must be subtracted from 180 degrees, and the remainder will be the obtuse angle. When a given angle is obtuse, or is one of 90 degrees, no ambiguity can occur, because neither of the other angles can then be obtuse, and the geometrical construction will only form one triangle.

Example 1. In the plane triangle ABC,  
Let AB be 345 feet,  
BC 232 feet,  
 $\angle A$   $37^{\circ} 20'$ :

Required the other parts.

First, to the angles at C and B (*fig. 398.*)

Fig. 398.

As the side	BC=232	-	-	Log.	2.365488
To sine opp. $\angle A = 37^\circ 20'$		-	-		9.782796
So side AB	=345	-	-		2.537819
<hr/>					
To sine opp. $\angle C = 115^\circ 36'$ or $64^\circ 24'$				=	9.955127
Add $\angle A = 37^\circ 20'$					37 20
The sum	=152 56	101 44			
Taken from	180 00	180 00			
Leaves $\angle B$	27 04	78 16			

It is to be observed here that the second and third logarithms are added (that is, the numbers are multiplied), and from the sum the first logarithm is subtracted (that is, division by the first number), which leaves the remainder 9.955127, which, by the table of sines, is found to be that of the angle  $115^\circ 36'$ , or  $64^\circ 24'$ .

To find the side AC.

As sine $\angle A = 37^\circ 30'$	-	-	Log.	9.782796
To opp. side BC = 232		-	-	2.365488
So sine $\angle B = \begin{cases} 27 & 04 \\ 78 & 16 \end{cases}$		-	-	9.658037
		-	-	9.990829
To opp. side AC = 174 07		-	-	2.240729
Or 374 56		-	-	2.573521

**Example 2.** In the plane triangle ABC,

Let AB=365 yards,

$\angle A = 57^\circ 12'$

$\angle B = 24^\circ 45'$

Herein two angles are given, whose sum is  $81^\circ 57'$ . Therefore  $180^\circ - 81^\circ 57' = \angle C$ , &c.

As sine $\angle C = 98^\circ 3'$	-	-	Log.	9.9956993
Is to AB = 365.	-	-	-	2.5622929
So sine $\angle B = 24^\circ 45'$	-	-	-	9.6218612
To side AC=154 33'	-	-	-	2.1884548

To find the side BC.

As sine $\angle B = 24^\circ 45'$	-	-	Log.	9.6210612
Is to AC =154 33	-	-	-	2.1884548
So sin. $\angle A = 57^\circ 12'$	-	-	-	9.9245721
To side BC=309 86	-	-	-	2.4911657

**1051. THEOREM II.** When two sides and their contained angle are given.

The given angle is first to be subtracted from  $180^\circ$  or two right angles, and the remainder will be the sum of the other two angles. Divide this remainder by 2, which will give the half sum of the said unknown angles; and using the following ratio, we have—

As the sum of the two given sides  
Is to their difference,  
So is the tangent of half the sum of their opposite angles  
To the tangent of half the difference of the same angles.

Now the half sum of any two quantities increased by their half difference gives the greater, and diminished by it gives the less. If, therefore, the half difference of the angles above found be added to their half sum, it will give the greater angle, and subtracting it will leave the lesser angle. All the angles thus become known, and the unknown side is then found by the former theorem.

For let ABC (*fig. 399.*) be the proposed triangle, having the two given sides AC, BC, including the given angle C. With the centre C and radius CA, the less of these two sides, describe a semicircle, meeting the other side BC produced in D, E, and the unknown side AB in A, G. Join AE, CG, and draw DE parallel to AE. Now BE is the sum of the given sides AC, CB, or of EC, CB; and BD is the difference of these given sides. The external angle ACE is equal to the sum of the two internal or given angles CAB, CBA; but the angle ADE at the circumference is equal to half the angle ACE at the centre; wherefore the same angle ADE is equal to half the sum of the given angles CAB, CBA. Also the external angle AGC of the triangle BGC is equal to the sum of the two internal angles GCB, GBC, or the angle GCB is equal to the difference of the two angles AGC, GBC; but the angle CAB is equal to the said angle AGC, these being opposite to the equal sides AC, CG; and the angle DAB at the circumference is equal to half the angle DCG at the centre. Therefore the angle DAB is equal to half the difference of the two given angles CAB, CBA, of which it has been shown that ADE or CDA is the half sum.

Fig. 399.

Now the angle DAE in a semicircle, is a right angle, or AE is perpendicular to AD; and DF, parallel to AE, is also perpendicular to AD: therefore AE is the tangent of CDA the half sum; and DF, the tangent of DAB, the half difference of the angles to the same radius AD, by the definition of a tangent. But the tangents AE, DF being parallel, it will be as BE : BD :: AE : DF; that is, as the sum of the sides is to the difference of the sides, so is the tangent of half the sum of the opposite angles to the tangent of half their difference.

It is to be observed, that in the third term of the proportion the cotangent of half the given angle may be used instead of the tangent of the half sum of the unknown angles.

Example. In the plane triangle ABC (*fig. 400.*),

Let AB = 345 ft.  
AC = 174.07 ft.  
 $\angle A = 37^\circ 20'$ .

Now, the side AB being 345	From	180° 00'
The side AC 174.07	Take $\angle A$	37 20
Their sum is 519.07	Sum of C and B	142 40
Their difference 170.93	Half sum of do.	71 20
As the sum of their sides AB, AC = 519.07	- - Log.	2.715226
To difference of sides AB, AC = 170.93	- -	2.232818
So tang. half sum $\angle s$ C and B = $71^\circ 20'$	- -	10.471298
To tang. half diff. $\angle s$ C and B = 44 16	- -	9.988890

These added, give  $\angle C = 115 36$

And subtracted, give  $\angle B = 27 4$

By the former theorem:—

As sine $\angle C$ $115^\circ : 36'$ , or $64^\circ 24'$	- - Log.	9.955126
To its opposite side AB 345	- -	2.537819
So sine $\angle A$ $37^\circ 20'$	- -	9.782796
To its opposite side BC 232	- -	2.365489

1052. THEOREM III. *When the three sides of a triangle are given.*

Let fall a perpendicular from the greatest angle on the opposite side, or base, dividing it into two segments, and the whole triangle into two right-angled triangles, the proportion will be—

As the base or sum of the segments  
Is to the sum of the other two sides,  
So is the difference of those sides  
To the difference of the segments of the base.

Then take half the difference of these segments, and add it to the half sum, or the half base, for the greater segment; and for the lesser segment subtract it.

Thus, in each of the two right-angled triangles there will be known two sides and the angle opposite to one of them, whence, by the first theorem, the other angles will be found.

For the rectangle under the sum and difference of the two sides is equal to the rectangle under the sum and difference of the two segments. Therefore, forming the sides of these rectangles into a proportion, their sums and differences will be found proportional.

Example. In the plane triangle ABC (*fig. 401.*),

Let AB = 345 ft.  
AC = 232 ft.  
BC = 174.07.

Letting fall the perpendicular CP,

Base BC : AC + BC :: AC - BC : AP - BP;

That is, 345 : 406.07 :: 57.93 : 68.18 = AP - BP;

Its half is 34.09

The half base is 172.50

The sum of these is 206.59 = AP

And their difference 138.41 = BP

Then, in the triangle APC right-angled at P,

As the side AC = 232	- Log.	2.365488
To sine opp. $\angle P$ = $90^\circ$	-	10.000000
So is side AP = 206.59	-	2.315109
To sine opp. $\angle ACP$ = $62^\circ 56'$	-	9.949621
Which subtracted from = 90 0		
Leaves $\angle A$ = 27 04		

Again, in the triangle BPC, right-angled at P,

As the side BC	= 174.07	-	Log. 2.240724
To sine opp. $\angle P$	= $90^\circ 00'$	-	10.000000
So is side BP	= 138.41	-	2.141168
To sine opp. $\angle BCP$	= $52^\circ 40'$	-	0.990444
Which taken from	90 00		
Leaves the $\angle B$	= 37 20		

Also the angle ACP = 62 56

Added to the angle BCP = 52.40

Gives the whole angle ACB = 115.36

So that the three angles are as follow, viz.  $\angle A 27^\circ 4'$ ;  $\angle B 37^\circ 20'$ ;  $\angle C 115^\circ 36'$ .

1053. THEOREM IV. *If the triangle be right-angled, any unknown part may be found by the following proportion:—*

As radius  
Is to either leg of the triangle,  
So is tangent of its adjacent angle  
To the other leg;  
And so is secant of the same angle  
To the hypotenuse.

For AB being the given leg in the right-angled triangle ABC, from the centre A with any assumed radius AD describe an arc DE, and draw DF perpendicular to AB, or parallel to BC. Now, from the definitions, DF is the tangent and AF the secant of the arc DE, or of the angle A, which is measured by that arc to the radius AD. Then, because of the parallels BC, DF, we have  $AD : AB :: DF : BC$ , and  $AF : AC$ , which is the same as the theorem expresses in words.

Fig. 402.

Note. Radius is equal to the sine of  $90^\circ$ , or the tangent of  $45^\circ$ , and is expressed by 1 in a table of natural sines, or by 10 in logarithmic sines.

Example 1. In the right-angled triangle ABC,

Let the leg AB = 162

$\angle A = 53^\circ 7' 48''$

As radius	= tang. $45^\circ$	-	Log. 10.000000
To leg AB	= 162	-	2.209515
So tang. $\angle A$	= $53^\circ 7' 48''$	-	10.124937
To leg BC	= 216	-	2.334452
So secant $\angle A$	= $53^\circ 7' 48''$	-	10.221848
To hypotenuse AC	= 270	-	2.431363

Note. There is another mode for right-angled triangles, which is as follows:—

ABC being such a triangle, make a leg AB radius; or, in other words, from the centre A and distance AB describe an arc BF. It is evident that the other leg BC will represent the tangent and the hypotenuse AC the secant of the arc BF or of the angle A.

In like manner, if BC be taken for radius, the other leg AB represents the tangent, and the hypotenuse AC the secant of the arc BG or angle C.

If the hypotenuse be made radius, then each leg will represent the sine of its opposite angle; namely, the leg AB the sine of the arc AE or angle C, and the leg BC the sine of the arc CD or angle A.

Fig. 403.

Then the general rule for all such cases is, that the sides of the triangle bear to each other the same proportion as the parts which they represent. This method is called making every side radius.

1054. If two sides of a right-angled triangle are given to find the third side, that may be found by the property of the squares of the sides (Geom. Prop. 32; viz. That the square of the hypotenuse or longest side is equal to both the squares of the two other sides together). Thus, if the longest side be sought, it is equal to the square root of the sum of the two shorter sides; and to find one of the shorter sides, subtract one square from the other, and extract the square root of the remainder.

1055. The application of the foregoing theorems in the cases of measuring heights and distances will be obvious. It is, however, to be observed, that where we have to find the length of inaccessible lines, we must employ a line or base which can be measured, and, by means of angles, which will be furnished by the use of instruments, calculate the lengths of the other lines.

## SECT. V.

## CONIC SECTIONS.

1056. The *conic sections*, in geometry, are those lines formed by the intersections of a plane with the surface of a cone, and which assume different forms and acquire different properties, according to the several directions of such plane in respect of the axis of the cone. Their species are five in number.

1057. DEFINITIONS.—1. A plane passing through the vertex of a cone meeting the plane of the base or of the base produced is called the *directing plane*. The plane VRX (fig. 404.) is the directing plane,
2. The line in which the directing plane meets the plane of the base or the plane of the base produced is called the *directrix*. The line RX is the directrix.
3. If a cone be cut by a plane parallel to the directing plane, the section is called a *conic section*, as AMB or AHI (fig. 405.)
4. If the plane of a conic section be cut by another plane at right angles passing along the axis of the cone, the common section of the two planes is called the *line of the axis*.
5. The point or points in which the line of the axis is cut by the conic surface is or are called the *vertex* or *vertices* of the conic section. Thus the points A and B (figs. 404. and 405.) are both vertices, as is the point A or vertex (fig. 406.).
6. If the line of the axis be cut in two points by the conic surface, or by the surfaces of the two opposite cones, the portion of the line thus intercepted is called the *primary axis*. The line AB (figs. 404. and 405.) and AH (fig. 406.) is called the primary axis.
7. If a straight line be drawn in a conic section perpendicular to the line of the axis so as to meet the curve, such straight line is called an *ordinate*, as PM in the above figures.
8. The *abscissa* of an ordinate is that portion of the line of axis contained between the vertex and an ordinate to that line of axis. Thus in figs. 404, 405, and 406. the parts AP, BP of the line of axis are the abscissas AP BP.
9. If the primary axis be bisected, the bisecting point is called the *centre* of the conic section.
10. If the directrix fall without the base of the cone, the section made by the cutting plane is called an *ellipse*. Thus, in fig. 404., the section AMB is an ellipse. It is evident that, since the plane of section will cut every straight line drawn from the vertex of the cone to any point in the circumference of the base, every straight line drawn within the figure will be limited by the conic surface. Hence the axis, the ordinates, and abscissas will be terminated by the curve.
11. If the directrix fall within the base of the cone, the section made by the cutting plane is called a *hyperbola*. Hence it is evident, that since the directing plane passes alike through both cones, the plane of section will cut each of them, and therefore two sections will be formed. And as every straight line on the surface of the cone and on the same side of the directing plane cannot meet the cutting plane, neither figure can be enclosed.
12. If the directrix touch the curve forming the base of the cone, the section made by the cutting plane is a *parabola*.

Fig. 404.

Fig. 405.

Fig. 406.

## OF THE ELLIPSIS.

1058. The primary axis of an ellipse is called the *major axis*, as AB (fig. 407.); and a straight line DE drawn through its centre perpendicular to it, and terminated at each extremity by the curve, is called the *minor axis*.

1059. A straight line VQ drawn through the centre and terminated at each extremity by the curve is called a *diameter*. Hence the two axes are also diameters.

Fig. 407.

1060. The extremities of a diameter which terminate in the curve are called the vertices of that diameter. Thus the points V and Q are the vertices of the diameter VQ.

1061. A straight line drawn from any point of a diameter parallel to a tangent at either extremity of the diameter to meet the curves is called an ordinate to the two abscissas. Thus PM, being parallel to a tangent at V, is an ordinate to the two abscissas VP, PQ.

1062. If a diameter be drawn through the centre parallel to a tangent at the extremity of another diameter, these two diameters are called conjugate diameters. Thus VQ and RS are conjugate diameters.

1063. A third proportional to any diameter and its conjugate is called the *parameter* or *latus rectum*.

1064. The points in the axis where the ordinate is equal to the semi-parameter are called the foci.

1065. THEOREM I. *In the ellipsis the squares of the ordinates of an axis are to each other as the rectangles of their abscissas.*

Let AVB (*fig. 408.*) be a plane passing through the axis of the cone, and AEB another section of the cone perpendicular to the plane of the former; AB the axis of the elliptic section, and PM, HI ordinates perpendicular to it; then it will be

$$PM^2 : HI^2 :: AP \times PB : AH \times HB.$$

For through the ordinates PM, HI draw the circular sections KML, MIN parallel to the base of the cone, having KL, MN for their diameters, to which PM, HI are ordinates as well as to the axis of the ellipse. Now, in the similar triangles APL, AHN,

$$AP : PL :: AH : HN,$$

And in BPK, BHM,

$$BP : PK :: BH : HM.$$

Taking the rectangles of the corresponding terms,

$$AP \times BP : PL \times PK :: AH \times BH : HN \times HM.$$

By the property of the circle,

$$\begin{aligned} PL \times PK &= PM^2 \text{ and } HN \times HM = HI^2. \text{ Therefore,} \\ AP \times BP : PM^2 :: AH \times HB : HI^2, \text{ or} \\ PM^2 : HI^2 :: AP \times BP : AH \times HB. \end{aligned}$$

Coroll. 1. If C be the centre of the figure,  $AP \times PB = CA^2 - CP^2$ , and  $AH \times HB = CA^2 - CH^2$ .

Therefore  $PM^2 : HI^2 :: CA^2 - CP^2 : CA^2 - CH^2$ . For  $AP = CA - CP$ , and  $PB = CA + CP$ ; consequently  $AP \times PB = (CA - CP)(CA + CP) = CA^2 - CP^2$ ; and in the same manner it is evident that  $AH \times HB = (CA + CH)(CA - CH) = CA^2 - CH^2$ .

Coroll. 2. If the point P coincide with the middle point C of the semi-major axis, PM will become equal to CE, and CP will vanish; we shall therefore have

$$PM^2 : HI^2 :: CA^2 - CP^2 : CA^2 - CH^2$$

$$\text{Now } CE^2 : HI^2 :: CA^2 : CA^2 - CH^2, \text{ or } CA^2 \times HI^2 = CE^2(CA^2 - CH^2).$$

1066. THEOREM II. *In every ellipsis the square of the major axis is to the square of the minor axis as the rectangle of the abscissas is to the square of their ordinate.*

Let AB (*fig. 409.*) be the major axis, DE the minor axis, C the centre, PM and HI ordinates to the axis AB; then will

$$CA^2 : CE^2 :: AP \times PB : PM^2.$$

For since by Theor. I.,  $PM^2 : HI^2 :: AP \times PB : AH \times HB$ ; and if the point H be in the centre, then AH and HB become each equal to CA, and HI becomes equal to CE; therefore

$$PM^2 : CE^2 :: AP \times PB : CA^2;$$

$$\text{And, alternately, } CA^2 : CE^2 :: AP \times PB : PM^2.$$

Coroll. 1. Hence, if we divide the two first terms of the analogy by AC, it will be  $CA : \frac{CE}{CA} :: AP \times PB : PM^2$ . But by the definition of parameter,  $AB : DE :: DE : \text{parameter}$ , or  $CA : CE :: 2CE : \text{parameter} = \frac{2CE^2}{CA}$ . Therefore  $\frac{2CE^2}{CA}$  is the parameter, which let us call P; then

$$AB : P :: AP \times PB : PM^2.$$

Coroll. 2. Hence  $CA^2 : CE^2 :: CA^2 - CP^2 : PM^2$ . For  $CA^2 - CP^2 = (CA - CP)(CA + CP) = (AP \times PB)$ .

Coroll. 3. Hence, also,  $A : P :: CA^2 - CP^2 : PM^2$ .

Fig. 408.

Fig. 409.

1067. THEOREM III. *In every ellipsis, the square of the minor axis is to the square of the major axis as the difference of the squares of half the minor axis and the distance of an ordinate from the centre on the minor axis to the square of that ordinate.*

Draw  $MQ$  (fig. 410.) parallel to  $AB$ , meeting  $CE$  in  $Q$ ; then will

$$CE^2 : CA^2 :: CE^2 - CQ^2 : QM^2;$$

For by Cor. 2. Theor. II.,  $CA^2 : CA^2 - CP^2 :: CE^2 : PM^2$ ;

Therefore by division,  $CA^2 : CP^2 :: CE^2 : CE^2 - PM^2$ ;

Therefore, since  $CQ = PM$  and  $CP = QM$ ;  $CA^2 : QM^2 :: CE^2 : CE^2 - CQ^2$ .

Coroll. 1. If a circle be described on each axis as a diameter, one being inscribed within the ellipse, and the other circumscribed about it, then an ordinate in the circle will be to the corresponding ordinate in the ellipsis as the axis belonging to this ordinate is to the axis belonging to the other; that is,

$$\begin{aligned} CA : CE :: PG : PM, \\ \text{and } CE : CA :: pg : pM; \\ \text{and since } CA^2 : CE^2 :: AP \times PB : PM^2, \\ \text{and because } AP \times PB = PG^2; \quad CA^2 : CE^2 :: PG^2 : PM^2, \\ \text{or } CA : CE :: PG : PM. \end{aligned}$$

In the same manner it may be shown that  $CE : CA :: pg : pM$ , or, alternately,  $CA : CE :: pM : pg$ ; therefore, by equality,  $PG : PM :: pM : pg$ , or  $PG : Cp :: CP : pg$ ; therefore  $CpG$  is a continued straight line.

Coroll. 2. Hence also, as the ellipsis and circle are made up of the same number of corresponding ordinates, which are all in the same proportion as the two axes, it follows that the area of the whole circle and of the ellipsis, as also of any like parts of them, are in the same ratio, or as the square of the diameter to the rectangle of the two axes; that is, the area of the two circles and of the ellipsis are as the square of each axis and the rectangle of the two; and therefore the ellipsis is a mean proportional between the two circles.

Coroll. 3. Draw  $MQ$  parallel to  $GC$ , meeting  $ED$  in  $Q$ ; then will  $QM = CG = CA$ ; and let  $R$  be the point where  $QM$  cuts  $AB$ ; then, because  $RMGC$  is a parallelogram,  $RM$  is equal to  $CG = CE$ ; and therefore, since  $QM$  is equal to  $CA$ , half the major axis and  $RM = CE$ , half the minor axis  $QR$  is the difference of the two semi-axes, and hence we have a method of describing the ellipsis. This is the principle of the trammel, so well known among workmen.

If we conceive it to move in the line  $DE$ , and the point  $R$  in the line  $AB$ , while the point  $M$  is carried from  $A$  towards  $E, B, D$ , until it return to  $A$ , the point  $M$  will in its progress describe the curve of an ellipsis.

1068. THEOREM IV. *The square of the distance of the foci from the centre of an ellipsis is equal to the difference of the square of the semi-axes.*

Let  $AB$  (fig. 412.) be the major axis,  $C$  the centre,  $F$  the focus, and  $FG$  the semi-parameter; then will  $CE^2 = CA^2 - CF^2$ . For draw  $CE$  perpendicular to  $AB$ , and join  $FE$ . By Cor. 2. Th. II.,  $CA^2 : CE^2 :: CA^2 - CF^2 : FG^2$ , and the parameter  $FG$  is a third proportional to  $CA, CE$ ; therefore  $CA^2 : CE^2 :: CE^2 : FG^2$ , and as in the two analogies the first, second, and fourth terms are identical, the third terms are equal; consequently

$$CE^2 = CA^2 - CF^2.$$

Coroll. 1. Hence  $CF^2 = CA^2 - CE^2$ .

Coroll. 2. The two semi-axes and the distance of the focus from the centre are the sides of a right-angled triangle  $CFE$ , and the distance  $FE$  from the focus to the extremity of the minor axis is equal to  $CA$  or  $CB$ , or to half the major axis.

Coroll. 3. The minor axis  $CE$  is a mean proportional between the two segments of the axis on each side of the focus. For  $CE^2 = CA^2 - CF^2 = (CA + CF) \times (CA - CF)$ .

1069. THEOREM V. *In an ellipsis, the sum of the lines drawn from the foci to any point in the curve is equal to the major axis.*

Let the points  $F, f$  (fig. 413.) be the two foci, and  $M$  a point in the curve; join  $FM$  and  $fM$ , then will  $AB = 2CA = FM + fM$ .

By Cor. 2. Th. II.,  $CA^2 : CE^2 :: CA^2 - CP^2 : PM^2$ ,

But by Th. IV.,  $CE^2 = CA^2 - CF^2$ ;

Therefore  $CA^2 : CA^2 - CF^2 :: CA^2 - CP^2 : PM^2$ ;

And by taking the rectangle of the extremes and means, and dividing the equation by  $CA^2$ , the result is—

Fig. 410.

Fig. 411.

Fig. 412.

Fig. 413.

$$PM^2 = CA^2 - CP^2 - CF^2 + \frac{CF^2 \cdot CP^2}{CA^2}.$$

And because  $FP^2 = (CF - CP)^2 = CF^2 - 2CF \cdot CP + CP^2$ ,

And since  $FM^2 = PM^2 + FP^2$ ,

Therefore  $FM^2 = CA^2 - 2CF \cdot CP + \frac{CF^2 \cdot CP^2}{CA^2}$ .

Extracting the root from each number,  $FM = CA - \frac{CF \cdot CP}{CA}$ .

In the same manner it may be shown that  $FM = CA + \frac{CF \cdot CP}{CA}$ ; therefore the sum of these is  $FM + fM = 2CA$ .

Coroll. 1. A line drawn from a focus to a point in the curve is called a radius vector, and the difference between either radius vector and half the major axis is equal to half the difference between the radius vectors. For, since

$$fM = CA - \frac{CF \cdot CP}{CA}; \text{ therefore, by transposition, } \frac{CF \cdot CP}{CA} = CA - fM.$$

Coroll. 2. Because  $\frac{CF \cdot CP}{CA}$  is a fourth proportional to  $CA$ ,  $CF$ ,  $CP$ ; therefore  $CA : CF :: CP : CA - fM$ .

Coroll. 3. Hence the difference between the major axis and one of the radius vectors gives the other radius vector. For, since  $FM + fM = 2CA$ ;

Therefore  $FM = 2CA - fM$ .

Coroll. 4. Hence is derived the common method of describing an ellipsis mechanically, by a thread or by points, thus:—Find the foci  $Ff$  (fig. 414.), and in the axis  $AB$  assume any point  $G$ ; then with the radius  $AG$  from the point  $F$  as a centre describe two arcs  $H, h$ , one on each side of the axis; and with the same radius from the point  $f$  describe two other arcs  $h, h$ , one on each side of the major axis. Again, with the distance  $GB$  from the point  $f$  describe two arcs, one on each side of the axis, intersecting the arcs  $HH$  in the points  $HH$ ; and with the same radius from the point  $f$  describe two other arcs, one on each side of the axis, intersecting the arcs described at  $h, h$  in the point  $h, h$ . In this manner we may find as many points as we please; and a sufficient number being found, the curve will be formed by tracing it through all the points so determined.

1070. THEOREM VI. The square of half the major axis is to the square of half the minor axis as the difference of the squares of the distances of any two ordinates from the centre to the difference of the squares of the ordinates themselves.

Let  $PM$  and  $HI$  (fig. 415.) be ordinates to the major axis  $AB$ ; draw  $MN$  parallel to  $AB$ , meeting  $HI$  in the point  $N$ ; then will  $PM = HN$ , and  $MN = PH$ , and the property to be demonstrated is thus expressed—

$$CA^2 : CE^2 :: CP^2 - CH^2 : HI^2 - HN^2.$$

Or by producing  $HI$  to meet the curve in the point  $K$ , and making  $CQ = CP$ , the property to be proved will be

$$\begin{aligned} & CA^2 : CE^2 :: PH \times HQ : KN. \\ \text{By Cor. 2. Theor. II. } & \begin{cases} CA^2 : CE^2 :: CA^2 - CP^2 : PM^2, \\ CA^2 : CE^2 :: CA^2 - CH^2 : HI^2. \end{cases} \\ \text{Therefore} & CA^2 - CH^2 : CA^2 - CP^2 :: HI^2 : PM^2 \text{ or } HN^2; \\ \text{But, by division,} & CA^2 - CH^2 : CP^2 - CH^2 :: HI^2 : HI^2 - HN^2. \\ \text{Alternately,} & CA^2 - CH^2 : HI^2 :: CP^2 - CH^2 : HI^2 - HN^2; \\ \text{And, since we have above,} & CA^2 - CH^2 : HI^2 :: CA^2 : CE^2, \\ \text{Therefore, by equality,} & CA^2 : CE^2 :: CP^2 - CH^2 : HI^2 - HN^2; \\ \text{But since} & CP^2 - CH^2 = (CP - CH)(CP + CH) = PH \times QH, \\ \text{And since} & HI^2 - HN^2 = (HI - HN)(HI + HN) = NI \times NK, \\ \text{Therefore} & CA^2 : CE^2 :: PH \times HQ : NI \times NK. \end{aligned}$$

Coroll. 1. Hence half the major axis is to half the minor axis, or the major axis is to the minor axis, as the difference of the squares of any two ordinates from the centre is to the rectangle of the two parts of the double ordinate, which is the greatest made of the sum and difference of the two semiordinates. For  $KN = HK + HN = HI + HN$ , which is the sum of the two ordinates, and  $NI = HI - HN$ , which is the difference of the two ordinates.

Coroll. 2. Hence, because  $CP^2 - CH^2 = (CP - CH)(CP + CH)$ , and since  $HI^2 - HN^2 = (HI - HN)(HI + HN)$ , and because  $CP - CH = PH$  and  $HI - HN = NI$ ; therefore  $CA^2 : CE^2 :: (CP + CH)PH : (HI + HN)NI$ .

Fig. 414.

Fig. 415.

**1071. THEOREM VII.** *In the ellipsis, half the major axis is a mean proportional between the distance of the centre and an ordinate, and the distance between the centre and the intersection of a tangent to the vertex of that ordinate.*

Fig. 416.

To the major axis draw the ordinates PM (fig. 416.) and HI, and the minor axis CE. Draw MN perpendicular to HI. Through the two points I, M draw MT, IT, meeting the major axis produced in T; then will  $CT : CA :: CA : CP$ . For,

By Cor. 1. Theor. VI.,  $CE^2 : CA^2 :: (IH + HN)IN : (PC + CH)HP$ ;

By Cor. 2. Th. II.,  $CE^2 : CA^2 :: PM^2 : CA^2 - CP^2$ ;

Therefore, by equality,  $PM^2 : CA^2 - CP^2 :: (IH + HN)IN : (PC + CH)HP$ .

By similar triangles,  $INM, MPT$ ;  $IN : NM$  or  $PH :: PM : PT$  or  $CT - CP$ .

Therefore, taking the rectangles of the extremes and means of the two last equations, and throwing out the common factors, they will be converted to the equation

$$PM(CT - CP)(CP + CH) = (CA^2 - CP^2)(IH + HN).$$

But when HI and PM coincide, HI and HN will become equal to PM, and CH will become equal to CP; therefore, substituting in the equation  $2CP$  for  $CP + PH$ , and  $2PM$  for  $IH + HN$ , and throwing out the common factors and the common terms, we have

$$CT \cdot CP = CA^2$$

$$\text{or } CT : CA :: CA : CP.$$

Coroll. 1. Since CT is always a third proportional to CP and CA, if the points P, A, B remain fixed, the point T will be the same; and therefore the tangents which are drawn from the point M, which is the intersection of PQ and the curve, will meet in the point T in every ellipsis described on the same axis AB.

Coroll. 2. When the outer ellipsis AQB, by enlarging, becomes a circle, draw QT perpendicular to CQ, and joining TM, then TM will be a tangent to the ellipsis at MM.

Coroll. 3. Hence, if it were required to draw a tangent from a given point T in the prolongation of the major axis to the ellipsis AEB, it will be found thus: — On AB describe the semicircle AQB. Draw a tangent TQ to the circle, and draw the ordinate PQ intersecting the curve AEB of the ellipsis in the point M; join TM; then TM is the tangent required. This method of drawing a tangent is extremely useful in practice.

**1072. THEOREM VIII.** *Four perpendiculars to the major axis intercepted by it and a tangent will be proportionals when the first and last have one of their extremities in the vertices, the second in the point of contact, and the third in the centre.*

Let the four perpendiculars be AD, PM, CE, BP, of which AD and BF have their extremities in the vertices A and B, the second in the point of contact M, and the third in the centre C; then will

Fig. 417.

$$AD : PM :: CE : BF.$$

$$\text{For, by Theor. VII., } TC : AC :: AC : CP;$$

$$\text{By division, } TC - AC : CA - CP :: TC : AC \text{ or } CB;$$

$$\text{That is, } TA : AP :: TC : CB.$$

$$\text{By composition, } TA : TA + AP :: TC : TC + CB;$$

$$\text{Therefore } TA : TP :: TC : TB.$$

But by the similar triangles TAD, TPM, TCE, and TBF, the sides TA, TP, TC, and TB are proportionals to the four perpendiculars AD, PM, CE, and BF; therefore

$$AD : PM :: CE : BF.$$

Coroll. 1. If AM and CF be joined, the triangles TAM and TCF will be similar.

For by similar triangles, the sides TD, TM, TE, TF are in the same proportion as the sides TA, TP, TC, TB.

$$\text{Therefore } TD : TM :: TE : TF;$$

$$\text{Alternately, } TD : TE :: TM : TF \text{ but TAD is similar to TCE;}$$

$$\text{Hence } TD : TE :: TA : TC;$$

$$\text{Therefore, by equality, } TA : TM :: TC : TF.$$

Coroll. 2. The triangles APM and CBF are similar;

$$\text{For } TA : TP :: TC : TB.$$

$$\text{By division, } TP : TP - TA :: TB : TB - TC;$$

$$\text{That is, } TP : AP :: TB : CB.$$

$$\text{Alternately, } TP : TB :: AP : CB \text{ but TPM is similar to TBF;}$$

$$\text{Consequently, } TP : TB :: PM : BF;$$

$$\text{Therefore, by equality, } AP : PM :: CB : BF.$$

Coroll. 3. If AF be drawn cutting PM in I, then will PI be equal to the half of PM

For, since  $AP : PM :: CB : BF$ , and, by the similar triangles  $API$ ,  $ABF$ ,

$$AP : PI :: AB : BF;$$

Therefore  $PM : PI :: CB : AB$ .

But  $CB$  is the half of  $AB$ ; therefore, also,  $PI$  is the half of  $PM$ .

1073. THEOREM IX. *If two lines be drawn from the foci of an ellipse to any point in the curve, these two lines will make equal angles with a tangent passing through that point.*

Let  $TM$  (fig. 418.) be a tangent touching the curve at the point  $M$ , and let  $F, f$  be the two foci; join  $FM, fM$ , then will the angle  $FMT$  be equal to the angle  $fMR$ . For draw the ordinate  $PM$ , and draw  $fR$  parallel to  $FM$ , then will the triangles  $TFM$  and  $TfR$  be similar; and by Cor. Theor. VII.,

Fig. 418

$$CA : CP :: CT : CA;$$

By Cor. 2. Theor. V.,

$$CA : CP :: CF : CA - FM;$$

Therefore, by equality,

$$CT : CF :: CA : CA - FM.$$

By division and composition,  $CT - CF : CT + CF :: FM : 2CA - FM$ ;

That is,

$$TF : Tf :: FM : fM.$$

By the similar triangles  $TFM, TfR$ ;  $TF : Tf :: FM : fR$ .

It therefore appears that  $fM$  is equal to  $fR$ , therefore the angle  $fMR$  is equal to the angle  $fRM$ ; but because  $FM$  and  $fR$  are parallel lines, the angle  $FMT$  is equal to the angle  $fRM$ ; therefore the angle  $FMT$  is equal to the angle  $fMR$ .

Coroll. 1. Hence a line drawn perpendicular to a tangent through the point of contact will bisect the angle  $FMf$ , or the opposite angle  $DMG$ . For let  $MN$  be perpendicular to the tangent  $TR$ . Then, because the angle  $NMT$  and  $NMR$  are right angles, they are equal to one another; and since the angles  $FMT$  and  $fMR$  are also equal to one another, the remaining angles  $NMF$  and  $NMf$  are equal to one another. Again, because the opposite angles  $FMN$  and  $IMG$  are equal to one another, and the opposite angle  $fMN$  and  $IMD$  are equal to one another; therefore the straight line  $MI$ , which is the line  $MN$  produced, will also bisect the angle  $DMG$ .

Coroll. 2. The tangent will bisect the angle formed by one of the radius vectors, and the prolongation of the other. For prolong  $FM$  to  $G$ . Then, because the angles  $RMN$  and  $RMI$  are right angles, they are equal to one another; and because the angles  $NMf$  and  $IMD$  are equal to one another, the remaining angles  $RMG$  and  $RMf$  are equal to one another.

*Scholium.* Hence we have an easy method of drawing a tangent to any given point  $M$  in the curve, or of drawing a perpendicular through a given point in the curve, which is the usual mode of drawing the joints for masonic arches. Thus, in order to draw the line  $IM$  perpendicular to the curve: produce  $FM$  to  $G$ , and  $fM$  to  $D$ , and draw  $MI$  bisecting the angle  $DMG$ ; then  $IM$  will be perpendicular to the tangent  $TR$ , and consequently to the curve.

As in optics the angle of incidence is always found equal to the angle of reflection, it appears that the foundation of that law follows from this theorem; for rays of light issuing from one focus, and meeting the curve in any point, will be reflected into lines drawn from these points to the other focus: thus the ray  $fM$  is reflected into  $MF$ : and this is the reason why the points  $Ff$  are called *foci*, or burning points. In like manner, a sound in one focus is reflected in the other focus.

1074. THEOREM X. *Every parallelogram which has its sides parallel to two conjugate diameters and circumscribes an ellipse is equal to the rectangle of the two axes.*

Let  $CM$  and  $CI$  (fig. 419.) be two semi conjugate diameters. Produce  $CA$  and  $MD$  to meet in  $T$ , and let  $AT$  meet  $DI$  in  $t$ . Draw  $Ih$  and  $PM$  ordinates to the axis, and draw half the minor axis  $CE$ . Produce  $DM$  to  $K$ , and draw  $CK$  perpendicular to  $DK$ : then will the parallelogram  $CIDM$  be equal to the rectangle, whose sides are  $CA$  and  $CE$ ; or four times the rectangle  $CIDM$  will be equal to the rectangle made of the two axes  $AB$  and  $GE$ .

Fig. 419.

By Cor. Theor. VII.,

$$\begin{cases} CA : CT :: CP : CA, \\ Ct : CA :: CA : CH; \end{cases}$$

Therefore

$$Ct : CT :: CP : CH.$$

By the similar triangles  $CtI, TCM$ ,

$$Ct : CT :: CI : TM;$$

By equality, therefore,

$$CI : TM :: CP : CH.$$

By the similar triangles  $CIh, TMP$ ,

$$CI : TM :: CH : PT;$$

Therefore, by equality,

$$CH : PT :: CP : CH.$$

Consequently

$$CP \times PT = CH^2.$$

But by Theor. VII.,

$$CP \times CT = CA^2;$$

Therefore, since  $CT = CP + PT$ ,

$$CP^2 + CP.PT = CA^2,$$

And, by transposition,

Hence, by equality,

Or, by transposition,

But by Cor. 2. Theor. I.,

And substituting  $CP^2$  for its equal  
 $CA^2 - CH^2$ , we have

Therefore

But again, by Theor. VII.,

By equality, therefore,

But by the similar triangles HIC, KCT,

Therefore

Consequently

$$CP.PT = CA^2 - CP^2;$$

$$CH^2 = CA^2 - CP^2,$$

$$CP^2 = CA^2 - CH^2.$$

$$CA^2 \times HI^2 = CE^2(CA^2 - CH^2),$$

$$CA^2 \times HI^2 = CE^2 \times CP^2;$$

$$CA : CP :: CE : HI.$$

$$CA : CP :: CT : CA;$$

$$CE : HI :: CT : CA.$$

$$HI : CI :: CK : CT;$$

$$CE : CI :: CK : CA;$$

$$CE \times CA = CI \times CK.$$

The ellipsis is of so frequent occurrence in architectural works, that an acquaintance with all the properties of the curve, and the modes of describing it, is of great importance to the architect. Excepting the circle, which may be called an ellipsis in which the two foci coincide, it is the most generally employed curve in architecture.

1075. PROBLEM I. *To describe an ellipsis.*

Let two pins at E and F (fig. 420.) be fixed in a plane within a string whose ends are made fast at C. If the point C be drawn equally tight while it is moved forward in the plane till it returns to the place from which it commenced, it will describe an ellipsis.

1076. PROB. II. *The two diameters AB and ED of an ellipse being given in position and magnitude, to describe the curve through points.*

Let the two diameters cut each other at C (fig. 421.). Draw AF and BG parallel to ED. Divide AC and AF each into the same number of equal parts, and draw lines, as in the figure, through the points of division; viz. those from the line AF to the point D, and the lines through AC to the point E; then through the points of intersection of the corresponding lines draw the curve AD, and in the same manner find the curve BD; then ADB will be the semi-ellipsis.

It is evident that the same method also extends to a circle by making CD equal to CA; (fig. 422.); and it appears that the two lines forming any point of the curve to be drawn will make a right angle with each other. For these lines terminate at the extremities of the diameter ED, and the point of concurrence being in the curve, the angle made by them must be a right angle; that is, the angle EAD, or E $\hat{A}$ D, or E $\hat{I}$ D, or E $\hat{A}$ D, is a right angle; and from this property we have the following method of drawing the segment of a circle through points found in the curve.

Thus, let AB be the chord, and CD be the versed sine of an arc of a circle, to describe the arc. Through D draw HI (fig. 423.) parallel to AB; join AD and DB; draw AH perpendicular to AD, and BI perpendicular to BD; divide AC and HD each into the same number of equal parts, and join the corresponding points; divide AF into the same number of equal parts, and through the points of division draw lines to D, and through the corresponding points where these lines meet the former draw a curve AD. In the same manner the other half BD may be drawn.

1077. PROB. III. *A diameter KH of an ellipsis being given, and an ordinate DL, to find the limits of the other conjugate diameter.*

Bisect KH in I (fig. 424.), through I draw EA parallel to DL, and draw DC and KB perpendicular to EA; from the point L with the distance K describe an arc cutting EA at F; join LF, and produce LF to C; make IE and IA each equal to LG; then will EA be a diameter conjugate to KH.

1078. PROB. IV. *A diameter KH and an ordinate DL of an ellipsis being given, to describe the curve.* (See fig. 424.)

Find the limits E and A of the other conjugate diameter by the preceding construction. Produce KB to  $g$ , and make K $g$  equal to IA or IE, and through the centre I of the curve and the point  $g$ , draw the straight line MN. Then, suppose the straight line KB $g$  to be an inflexible rod, having the point B marked upon it. Move the rod round, so that the point  $g$  on the rod may be in the line MN, while the point B is in the line EA; then, at any instant of the motion, the place

Fig. 420.

Fig. 421.

Fig. 422.

Fig. 423.

Fig. 424.

of the point  $K$  on the plane whereon the figure is to be drawn may be marked; the points thus found will be in the curve. Instead of a rod, a slip of paper may be used, and in some cases a rod with adjustable points to slide in a cross groove, and a sliding head for a pencil is convenient; and such an instrument is called a *trammel*.

When the diameters  $KH$  and  $EA$  (fig. 425.) are at right angles to each other, the straight line  $Kq$  coincides with the diameter  $KH$ , and consequently the line  $MN$ , on which the point  $q$  of the inflexible line  $Kq$  moves, will also fall upon the diameter  $KH$ . Therefore in this case nothing more is required to find the limits of the other diameter, than to take the half diameters  $IK$ ,  $KH$  of the given diameters, and from the extremity  $L$  with that distance describe an arc cutting the unlimited diameter in the point  $F$ ; then drawing  $LF$ , and producing it to  $q$ , and making  $IE$  and  $IA$  each equal to  $qL$ ,  $EA$  will be the other diameter; and since the two diameters are at right angles to each other, they are the two axes given in position and magnitude, and thus the curve may be described as before.

FIG. 425.

A method of describing the curve from any two conjugate diameters is occasionally of considerable use, and particularly so in perspective. For, in every representation of a circle in perspective, a diameter and a double ordinate may be determined by making one of the diameters of the original circle perpendicular to the plane of the picture and the other parallel to it; and then the representation of the diameter of the original circle, which is perpendicular to the intersecting line, will be a diameter of the ellipsis, which is the representation of that circle; and the representation of the diameter of the circle which is parallel to the intersecting line will become a double ordinate to the diameter of the ellipsis which is the perspective representation of the circle.

1079. PROB. V. *Through two given points A and B to describe an ellipsis, the centre C being given in position and the greater axis being given in magnitude only.*

About the centre  $C$  (fig. 426.) with a radius equal to half the greater axis describe a circle  $HEDG$ ; join  $AC$  and  $BC$ ; draw  $AD$  perpendicular to  $AC$ , and  $BE$  perpendicular to  $BC$ , cutting the circumference in the points  $D$  and  $E$ ; draw also  $BF$  parallel to  $AC$ , and find  $BF$ , which is a fourth proportional to  $AD$ ,  $AC$ , and  $BE$ ; through the point  $F$  and the centre  $C$  draw  $FG$  to cut the circle in  $H$  and  $G$ , and  $GH$  is the major axis of the ellipsis. By drawing an ordinate  $Bq$ , the curve may be described by the preceding problem, having the axis  $GH$  and the ordinate  $Bq$ .

FIG. 426.

1080. PROB. VI. *Through a given point in the major axis of a given ellipsis to describe another similar ellipsis which shall have the same centre and its major axis on the same straight line as that of the given ellipsis.*

Let  $ACBD$  (fig. 427.) be the given ellipsis, having  $AB$  for its major axis and  $CD$  for its minor axis, which are both given in position and magnitude. It is required to draw a similar ellipsis through the point  $G$  in the major axis  $AG$ . Draw  $BK$  perpendicular and  $CK$  parallel to  $AB$ , and join  $KE$ . Again, draw  $GL$  perpendicular to  $AB$  cutting  $EK$  at  $L$ , and draw  $LH$  parallel to  $AB$  cutting  $CD$  in  $H$ . On the axis  $CD$  make  $EI$  equal to  $EH$ , and on the axis  $AB$  make  $EF$  equal to  $EG$ . Then, having the major axis  $AB$ , and the minor axis  $FG$ , the ellipsis  $FIGH$  may be described, and when drawn, it will be similar to the given ellipsis  $ADBC$ .

FIG. 427.

1081. PROB. VII. *Through any given point  $p$ , within the curve of a given ellipsis to describe another ellipsis which shall be similar and concentric to the given one.*

Let  $C$  (fig. 428.) be its centre. Draw the straight line  $CpP$ , cutting the curve of the given ellipsis in  $P$ . In such curve take any other number of points  $Q, R, S$ , &c., and join  $QC, RC, SC$ , &c.; join  $PQ$  and draw  $pq$  parallel thereto cutting  $QC$  at  $q$ : join  $PR$  and draw  $pr$  parallel to  $PR$ , cutting  $RC$  at  $r$ ; join  $PS$  and draw  $ps$  parallel to  $PS$  cutting  $SC$  in  $s$ . The whole being completed, and the curve  $p, s, t, u$  drawn through the points  $p, q, r, s$ , &c., the figure will be similar and concentric to the given ellipse  $P, S, T, U$ ; or when the points at the extremities for one half of the curve have been drawn, the other half may be found by producing the diameter to the opposite side, and making the part produced equal to the other part.

FIG. 428.

1082. PROB. VIII. *About a given rectangle  $ABCD$  to describe an ellipsis which shall have its major and minor axes respectively parallel to the sides of the rectangle and its centre in the points of intersection of the two diagonals.*

Bisect the sides  $AD$  and  $AB$  (fig. 429.) of the rectangle respectively at  $L$  and  $O$ ;

through L draw GH parallel to AB cutting the opposite side BC of the rectangle in M, and through the point O draw KI parallel to AD or BC cutting the opposite side DC in N. In NK or NK produced, make NQ equal to NC, and join CQ; draw QR parallel to GH cutting CB or CB produced in R; make EH and EG each equal to QC, as also EI and EK each equal to PC; then will GH be the major axis and KI the minor axis of the ellipsis required.

Fig. 429.

The demonstration of this method, in which the line QK has nothing to do with the construction, is as follows:—

By the similar triangles CPM and COR, we have  $CP : CM :: CQ : CR$ .

But because MP is equal to MC = EN, and since CR is equal to RQ = EM,

And, by construction, since PC is equal to EI or EK, and QC is equal to EG or EH,

$EI : EN :: EH : EM$ , or, alternately,  $EI : EH :: EN : EM$ .

But EN is equal to MC, and EM equal to NC;

Whence  $EI : EH :: MC : CN$ .

But since the wholes are as the halves, we shall have  $KI : GH :: BC : CD$ .

This problem is useful in its application to architecture about domes and pendentives, as well as in the construction of spheroidal ceilings and other details.

#### OF THE HYPERBOLA.

1083. The direction of a plane cutting a cone, which produces the form called the hyperbola, has been already described; its most useful properties will form the subject of the following theorems, which we shall preface with a few definitions:—

1. The primary axis of an hyperbola is called the *transverse axis*.
2. A straight line drawn through the centre of an hyperbola and terminated at each extremity by the opposite curves is called a *diameter*.
3. The extremities of a diameter terminated by the two opposite curves are called the *vertices of that diameter*.
4. A straight line drawn from any point of a diameter to meet the curve parallel to a tangent at the extremity of that diameter is called an *ordinate* to the two abscissas.
5. A straight line which is bisected at right angles by the transverse axis in its centre, and which is a fourth proportional to the mean of the two abscissas, their ordinate, and the transverse axis, is called the *conjugate axis*.
6. A straight line which is a third proportional to the transverse and conjugate axis is called the *latus rectum* or *parameter*.
7. The two points in the transverse axis cut by ordinates which are equal to the semi-parameter are called the *foci*.

1084. THEOREM I. *In the hyperbola the squares of the ordinates of the transverse axis are to each other as the rectangular of their abscissas.*

Let QVN (fig. 430.) be a section of the cone passing along the axis VD, the line of section of the directing plane, HB the line of axis of the cutting plane, the directing and cutting plane being perpendicular to the plane QVN. Let the cone be cut by two planes perpendicular to the axis passing through the two points P, H, meeting the plane of section in the lines PM, HI, which are ordinates to the circles and to the figure of the section, of the same time.

Fig. 430.

By the similar triangles APL and AHN,  $AP : PL :: AH : HN$ ;

And by the similar triangles BPK and BHQ,  $BP : PK :: BH : HQ$ .

Therefore, taking the rectangles of the corresponding terms,  $AP \times BP : PL \times PK :: AH \times BH : HN \times HQ$ .

But in the circle,  $PL \times PK = PM^2$ , and  $HN \times HQ = HI^2$ ;

Therefore  $AP \times BP : PM^2 :: AH \times BH : HI^2$ ,

Or, alternately,  $PM^2 : HI^2 :: AP : PB : AH : BH$ .

1085. THEOREM II. *In the hyperbola, as the square of the transverse axis is to the square of the conjugate axis, so is the rectangle of the abscissas to the square of their ordinate.*

Let AB (fig. 431.) be the transverse axis, GE the conjugate axis, C being the centre of the opposite curves; also let HI and PM be ordinates as before; then will

$AB^2 : GE^2 :: PA \times PB : PM^2$ ,

Or  $CA^2 : CE^2 :: PA \times PB : PM^2$ .

By Theor. I.,  $PA \times PB : HA \times HB :: PM^2 : HI^2$ ;

Alternately,  $PA \times PB : PM^2 :: HA \times HB : HI^2$ .

But  $HA \times HB : HI^2 :: AB^2 : GE^2$ ;

Therefore  $AB^2 : GE^2 :: PA \times PB : PM^2$ .

Fig. 431.

Coroll. Hence  $AB^2 : GE^2 :: CP^2 - CA^2 : PM^2$  (*fig. 432.*). For let the cutting plane of the opposite hyperbola intersect two circles parallel to the base in HI and PM, and let the cone be cut by another plane parallel to the base, passing through the centre C of the transverse axis, and let  $mn$  be the diameter of the circle made by the plane QVN.

Then  $ACm$ ,  $APK$  are similar, and  $AC : Cm :: AP : PK$ .  
And as  $BCn$ ,  $BPL$  are similar,  $BC : Cn :: BP : PL$ .

Therefore, taking the rectangles of the corresponding terms,  
 $BC \times AC : Cn \times Cm :: BP \times AP : PL \times PK$ .

But  $BC = AC$ ;  $Cm \times Cn = Ct^2$ ; and  $PL \times PK = PM^2$ .  
Therefore  $AC^2 : Ct^2 :: AP \times BP : PM^2$ .

Though  $Ct$  is not in the same plane, it is what is usually called the semi-conjugate axis, and it agrees with what has been demonstrated in the first part of this proposition.

1086. THEOREM III. *In the hyperbola, the square of the semi-conjugate axis is to the square of the semi-transverse axis as the sum of the squares of the semi-conjugate axis and of the ordinate parallel to it is to the square of the abscissas.*

Let  $AB$  (*fig. 433.*) be the transverse axis,  $GE$  the conjugate,  $C$  the centre of the figure, and  $PM$  an ordinate, then will

$$GE^2 : AB^2 :: CE^2 + PM^2 : CP^2.$$

For, by Theor. II.,  $CE^2 : CA^2 :: PM^2 : CP^2 - CA^2$ ,

And, by composition,  $CE^2 : CA^2 :: CE^2 + PM^2 : CP^2$ .

This demonstration may be also applied to what are called conjugate hyperbolas.

1087. THEOREM IV. *In the hyperbola, the square of the distance of the focus from the centre is equal to the sum of the squares of the semi-axes.*

Let  $AB$  (*fig. 434.*) be the transverse axis,  $CE$  the semi-conjugate. In  $AB$ , produced within the curve each way, let  $F$  be one focus; and  $f$  the other, and let  $FG$  be the semi-parameter then  $CF^2 = CA^2 + CE^2$ .

For, by Theor. I.,  $CA^2 : CE^2 :: FA \times FB : FG^2$ ;

But, by property of parameter,  $CA^2 : CE^2 :: CE^2 : FG^2$ .

Therefore  $CE^2 = AF \times FB = CF - CA$ ;

And, by transposition,  $CF^2 = CA^2 + CE^2$ .

Coroll. 1. The two semi-axes, and the distance of the focus from the centre, are the sides of a right-angled triangle  $CEA$ , of which the distance  $AE$  is the distance of the focus from the centre.

Coroll. 2. The conjugate axis  $CE$  is a mean proportional between  $FA$  and  $FB$ , or between  $fB$  and  $fA$ , for  $CE^2 = CF^2 - CA^2 = (CF + CA) \times (CF - CA) = BF \times AF$ .

1088. THEOREM V. *The difference of the radius vectors is equal to the transverse axis.*

That is,  $fM - FM = AB = 2CA = 2CB$ .

For  $CA^2 : CE^2 :: CP^2 - CA^2 : PM^2$ ;

And  $CE^2 = CF^2 - CA^2$ .

Therefore  $CA^2 : CF^2 - CA^2 :: CP^2 - CA^2 : PM^2$ .

And by taking the rectangle of the extremes and means, and dividing by  $CA^2$ ,

$$PM^2 = \frac{CF^2 \times CP^2}{CA^2} - CF^2 - CF^2 + CA^2;$$

But  $FP^2 = (CP - CF)^2 = CP^2 - 2CP \times CF + CF^2$ ,

And  $FM^2 = PM^2 + FP^2$ .

Therefore  $FM^2 = \frac{CF^2 \times CP^2}{CA^2} - 2CP \times CF + CA^2$ .

Now each side of this equation is a complete square.

Therefore, extracting the root of each number,

$$FM = \frac{CF \times CP}{CA} - CA.$$

In the same manner we find

$$fM = \frac{CF \times CP}{CA} + CA;$$

And, subtracting the upper equation from the lower,  $fM - FM = 2CA$ .

Coroll. 1. Hence is derived the common method of describing the hyperbolic curve mechanically. Thus:—In the transverse axis  $AB$  produced (*fig. 435.*), take the foci  $F, f$ , and any point  $I$  in the straight line  $AB$  so produced. Then, with the radii  $AI, BI$ , and the

Fig. 432.

Fig. 433.

Fig. 434.

Fig. 435.

centre F, *f*, describe arcs intersecting each other; call the points of intersection E, then E will be a point in the curve; with the same distances another point on the other side of the axis may be found. In like manner, by taking any other points I, we may find two more points, one on each side of the axis, and thus continue till a sufficient number of points be found to describe the curve by hand. By the same process, we may also describe the opposite hyperbolas.

Coroll. 2. Because  $\frac{CF \times CP}{CA}$  is a fourth proportional, CA, CF, CP  
 CA : CF :: CP : CA + FM.

1089. THEOREM VI. *As the square of the semi-transverse axis is to the square of the semi-conjugate, so is the difference of the squares of any two abscissas to the difference of the squares of their ordinates.*

By Theor. II.,  $\begin{cases} CA^2 : CE^2 :: CP^2 - CA^2 : PM^2 \text{ (fig. 436.)} \\ CA^2 : CE^2 :: CH^2 - CA^2 : HI^2. \end{cases}$

Therefore, by equality,  $CH^2 - CA^2 : CP^2 - CA^2 :: HI^2 : PM^2$  or  $HN^2$ ;

And, by division,  $CH^2 - CA^2 : CH^2 - CP^2 :: HI^2 : HI^2 - HN^2$ ;

Alternately,  $CH^2 - CA^2 : HI^2 :: CH^2 - CP^2 : HI^2 - HN^2$ .

But  $CH^2 - CA^2 : HI^2 :: CA^2 : CE^2$

Therefore  $CA^2 : CE^2 :: CH^2 - CP^2 : HI^2 - HN^2$ .

Coroll. 1. If IH be produced to K, and CQ be made equal to CP, then will  $CH^2 - CP^2 = (CH + CP)(CH - CP) = (CP + CH)PH$ ; and  $HI^2 - HN^2 = (HI + HN)(HI - HN) = (HI + HN)NI$ . Therefore the analogy resulting becomes

$$CA^2 : CE^2 :: (CP + CH)PH : (HI + HN)NI.$$

So that the square of the transverse axis is to the square of the conjugate, or the square of the semi-transverse is to the square of the semi-conjugate, as the rectangle of the sum and difference of the two ordinates from the centre is to the rectangle of the sum and difference of these ordinates.

1090. THEOREM VII. *If a tangent and an ordinate be drawn from any point in an hyperbola to meet the transverse axis, the semi-transverse axis will be a mean proportional between the distances of the two intersections from the centre.*

For (fig. 437.)  $CE^2 : CA^2 :: (IH + HN)IN :: (PC + CH)HP$ ;

And by Theor. I.,  $CE^2 : CA^2 :: PM^2 : CP^2 - CA^2$ ;

By equality,  $PM^2 : CP^2 - CA^2 :: (IH + HN)IN : (PC + CH)HP$ ;

And by similar triangles INM, MPT,  $IN : NM$  or  $PH :: PM : PT$  or  $CP - CT$ .

Therefore, taking the rectangles of the extremes and means of the two last equations, and neglecting the common factors, it will be  $PM(CP - CT)(CP + CH) = (CP^2 - CA^2)(IH + HN)$ ; but when IH and PM coincide, IH and HN each become equal to PM, and CH equal to CP: therefore in the equation substitute  $2CP$  for  $CP + CH$ , and  $2PM$  for  $IH + HN$ , and neglecting the common factors and common terms, the result is  $CT.CP = CA^2$ , or  $CT : CA :: CA : CP$ .

Coroll. Since CT is always a third proportional to CP, CA; suppose the points P and A to remain constant, the point T will also remain all the tangents will meet in the point T which are drawn from the extremity of the ordinate M of every hyperbola described on the same axis AB.

1091. THEOREM VIII. *Four perpendiculars to the transverse axis intercepted by it and a tangent, will be proportionals when the first and last have one of their extremities in each vertex, the second in the point of contact, and the third in the centre.*

Let the four perpendiculars be AD, PM, CE, BF (fig. 438.), whereof AD and BF have their extremities in the vertices A and B, and the second in the point of contact M of the tangent and the curve, and the third in the centre C.

Then will  $AD : PM :: CE : BF$ .

For, by Theor. VII.,  $CT : CA :: CA : CP$ ,

And, by division,  $CA - CT : CP - CA :: CT : CA$  or  $CB$ ;

That is,  $AT : AP :: CT : CB$ ;

By composition,  $AT : AT + AP :: CT : CT + CB$ .

Therefore  $AT : TP :: CT : BT$ .

Fig. 436.

Fig. 437.

Fig. 438.

But by the similar triangles TAD, TPM, TCE, and TBF, the sides AT, PT, CT, and BT are proportional to the four perpendiculars AD, PM, CE, BF.

Therefore  $AP : PM :: CE : BF$ .

1092. THEOREM IX. *The two radius vectors meeting the curve in the same point will make equal angles with a tangent passing through that point. (Fig. 439.)*

For, by Theor. VII.,  $CA : CP :: CT : CA$ ;  
By Cor. 2. Theor. V.,  $CA : CP :: CF : CA + FM$ ;  
By equality,  $CT : CF :: CA : CA + FM$ ;  
By division and composition,  $CF - CT : CF + CT :: FM : 2CA + FM$ ;  
 $FT : fT :: FM : fR$ ;

And by the similar triangles TFM, TfR, FT : fT :: FM : fR.  
Therefore fR is equal to fM; consequently the angle fRM is equal to the angle fMR: and because fR is parallel to fM, the angle FMT is equal to the angle fRM; therefore the angle FMT is equal to the angle fRM.

1093. PROBLEM I. *To describe an hyperbola by means of the end of a ruler moveable on a pin F (fig. 440.) fixed in a plane, with one end of a string fixed to a point E in the same plane, and the other extremity of the string fastened to the other end C of the ruler, the point C of the ruler being moved towards G in that plane.*

While the ruler is moving, a point D being made to slide along the edge of the ruler, kept close to the string so as to keep each of the parts CD, DE of the string taught, the point D will describe the curve of an hyperbola.

If the end of the ruler at F (fig. 441.) be made moveable about the point E, and the string be fixed in F and to the end C of the ruler, as before, another curve may be described in the same manner, which is called the *opposite hyperbola*: the points E and F, about which the ruler is made to revolve, are the foci.

There are many occasions in which the use of this conic section occurs in architectural details. For instance, the profiles of many of the Grecian mouldings are hyperbolic; and in conical roofs the forms are by intersections such that the student should be well acquainted with the methods of describing it.

1094. PROB. II. *Given the diameter AB, the abscissa BC, and the double ordinate DE in position and magnitude, to describe the hyperbola. (Fig. 442.)*

Through B draw FG parallel to DE, and draw DF and EG parallel to AB.

Divide DF and DC each into the same number of equal parts, and from the points of division in BF draw lines to B, also from the points of division in DC draw straight lines to A; then through the points of intersection found by the lines drawn through the corresponding points draw the curve DB. In like manner the curve EB may be drawn so that DBE will form the curve on each side of the diameter AB. If the point A be considered as the vertex, the opposite hyperbola HAI may be described in the same manner, and thus the two curves formed by cutting the opposite cones by the same plane will be found. By the theorists, the hyperbola has been considered a proper figure of equilibrium for an arch whose office is to support a load which is greatest at the middle of the arch, and diminishes towards the abutments. This, however, is matter of consideration for another part of this work.

Fig. 439.

Fig. 440.

Fig. 441.

Fig. 442.

# OF THE PARABOLA.

1095. DEFINITIONS.—1. The parameter of the axis of a parabola is a third proportional to the abscissa and its ordinate.
2. The focus is that point in the axis where the ordinate is equal to the semi-parameter.
3. The diameter is a line within the curve terminated thereby, and is parallel to the axis.
4. An ordinate to any diameter is a line contained by the curve and that diameter parallel to a tangent at the extremity of the diameter.

1096. THEOREM I. *In the parabola, the abscissas are proportional to the squares of their ordinates.*

Let QVN (fig. 443.) be a section of the cone passing along the axis, and let the directrix RX pass through the point Q perpendicular to QN, and let the parabolic section be ADI meeting the base QIND of the cone in the line DI, and the diameter QN in the point H; also let KML be a section of the cone parallel to the base QIN intersecting the plane VQN in the line KL, and the section ADI in PM. Let P be the point of concurrence of the three planes QVN, KML, AHI, and let H be the point of concurrence of the three planes QVN, KML, AHI; then, because the planes VRX and ADI are parallel, and the plane AQN is perpendicular to the plane ARX, the plane ADI is also perpendicular to the plane AQN. Again, because the plane QIN is perpendicular to the plane QVN, and the plane KML is parallel to the plane QIN, the plane KML is perpendicular to the plane QVN: therefore the common sections PM and HI are perpendicular to the plane AQN; and because the plane KML is parallel to the plane QIN; and these two planes are intersected by the plane QVN, their common sections KL and QN are parallel. Also, since PM and HI are each perpendicular to the plane QVN, and since KL is the common section of the planes QVN, KML, and QN in the common section of the planes QVN, QIN; therefore PM and HI are perpendicular respectively to KI and QN.

Fig. 443.

Consequently

$$AP : AH :: PM^2 : HI^2.$$

For, by the similar triangles APL, AHN,  $AP : AH :: PL : HN$ ,

Or

$$AP : AH :: KP \times PL : KP \times HN.$$

But, by the circle

$$KML, \quad KP \times PL = PM^2,$$

And, by the circle

$$QIN, \quad QH \times HN = HI^2. \text{ But } QH = KP;$$

Therefore

$$KP \times HN = HI^2.$$

Therefore, by substitution.

$$AP : AH :: PM^2 : HI^2.$$

Coroll. By the definition of the parameter, which we shall call P,

$$AP : PM :: PM : P = \frac{PM^2}{PA},$$

$$\text{And } P \times AP = PM^2, \text{ or } P \times AH = HI^2.$$

$$\text{Therefore } P : PM :: PM : AP, \text{ or } P : HI :: HI : AH.$$

1097. THEOREM II. *As the parameter of the axis is to the sum of any two ordinates, so is the difference of these ordinates to the difference of their abscissas.*

That is,  $P : HI + PM :: HI - PM : AH - AP$ .

$$\text{For since by Cor. Theor. I. } \begin{cases} P = \frac{PM^2}{AP}, \\ P = \frac{HI^2}{AH}; \end{cases}$$

Fig. 444.

Multiplying the first of these equations by AP and the second by AH,

$$\text{they become } \begin{cases} P \times AP = PM^2, \\ P \times AH = HI^2. \end{cases}$$

Subtract the corresponding numbers of the first equation, and  $P(AH - AP) = HI^2 - PM^2$ . But the difference of two squares is equal to a rectangle under the sum and difference of their sides.

$$\text{And } HI^2 - PM^2 = (HI + PM)(HI - PM).$$

$$\text{Therefore } P(AH - AP) = (HI + PM)(HI - PM).$$

$$\text{Consequently } P : HI + PM :: HI - PM : AH - AP;$$

Or, by drawing KM parallel to AH, we have  $GK = PM + HI$ , and  $KI = HI - PM$ ; and since  $PH = AH - AP$ ;  $P : GK :: KI : PH$ , or  $KM$ .

Coroll. Hence, because

$$P \times KM = GK \times KI;$$

And since

$$HI^2 = P \times AH;$$

Therefore, by multiplication,  $KM \times HI^2 = GK \times KI \times AH$ , or

$$AH : KM :: HI^2 : GK \times KI.$$

So that any diameter MK is as the rectangle of the segments GK, KI of the double ordinate GI. From this a simple method has been used of finding points in the curve, so as to describe it.

1098. THEOREM III. *The distance between the vertex of the curve and the focus is equal to one fourth of the parameter.*

Let LG (fig. 445.) be a double ordinate passing through the focus, then LG is the parameter. For by the definition of parameter  $AF : FG :: FG : P = 2FG$ .

$$\text{Therefore } 2AF = FG = \frac{1}{2}LG;$$

$$\text{Consequently } AF = \frac{1}{4}LG.$$

Fig. 445.

1099. **THEOREM IV.** *The radius vector is equal to the sum of the distances between the focus and the vertex, and between the ordinate and the vertex. (Fig. 446.)*

That is,  $FM = AP + AF$ .  
 For  $FP = AP - AF$ ;  
 Therefore  $FP^2 = AP^2 - 2AP \times AF + AF^2$ .  
 But, by Cor. Theor. II.,  $PM^2 = P \times AP = 4AF \times AP$ .  
 Therefore, by addition,  $FP^2 + PM^2 = AP^2 + 2AF \times AP + AF^2$ .

Fig. 446.

But by the right-angled triangles,  $FP^2 + PM^2 = FM^2$ ;  
 And therefore  $FM^2 = AP^2 + 2AF \times AP + AF^2$ .  
 Hence, extracting the roots,  $FM = AP + AF = 2AF + FP$ ;  
 Or by making  $AG = AF$ ,  $FM = GP$ .

Coroll. 1. If through the point G (fig. 447.) the line GQ be drawn perpendicular to the axis, it is called the directrix of the parabola.

By the property shown in this theorem, it appears that if any line QM be drawn parallel to the axis, and if FM be joined, the straight line FM is equal to QM; for QM is equal to GP.

Coroll. 2. Hence, also, the curve is easily described by points. Take AG equal to AF, (fig. 447.), and draw a number of lines M, M perpendicular to the axis AP; then with the distances GP, GP, &c. as radii, and from F as a centre, describe arcs on each side of AP, cutting the lines MM, MM, &c. at MN, &c.; then through all the points M, M, M, &c. draw a curve, which will be a parabola.

Fig. 447.

Fig. 448.

1100. **THEOREM V.** *If a tangent be drawn from the vertex of an ordinate to meet the axis produced, the subtangent PT (fig. 448.) will be equal to twice the distance of the ordinate from the vertex.*

If MT be a tangent at M, the extremity of the ordinate PM; then the sub-tangent PT is equal to twice AP. For draw MK parallel to AH,

Then, by Theor. II.,  $KM : KI :: GK : P$ ;  
 And as MKI, TPM are similar,  $KM : KI :: PT : PM$ .  
 Therefore, by equality,  $P : PM :: GK : PT$ ;  
 And by Cor. Theor. I.,  $P : PM :: PM : AP$ .  
 Therefore, by equality,  $AP : PT :: PM : GK$ .

But when the ordinates HI and PM coincide, MT will become a tangent, and GK will become equal to twice PM.

Therefore  $AP : PT :: PM : 2PM$ , or  
 $PT = 2AP$ .

From this property is obtained an easy and accurate method of drawing a tangent to any point of the curve of a parabola. Thus, let it be required to draw a tangent to any point M in the curve. Produce PA to T (fig. 449.), and draw MP perpendicular to PT, meeting AP in the point P. Make AP equal to AP, and join MT, which will be the tangent required.

Fig. 449.

Fig. 450.

Produce PA to T (fig. 450.), and let MT be a tangent at M; then will  $FT = FM$ .

For  $FT = AF + AT$ ;  
 But, by last theorem,  $AP = AT$ ;  
 Therefore  $FT = AF + AP$ .  
 But, by Theorem III.,  $FM = AF + AP$ ;  
 Therefore, by equality,  $FM = FT$ .

Coroll. 1. If MN be drawn perpendicular to MT to meet the axis in N, then will  $FN = FM = FT$ . For draw FH perpendicular to MT, and it also bisects MT, because  $FM = FT$ ; and since HF and MN are parallel, and MT is bisected in H, the line TN will also be bisected in F. It therefore follows that  $FN = FM = FT$ .

Coroll. 2. The subnormal PN is a constant quantity, and it is equal to half the parameter, or to  $2AF$ . For since TMN is a right angle,

Therefore  $2AP$  or  $TP : PM :: PM : PN$ .  
 But, by the definition of parameter,  $AP : PM :: PM : P$ ;  
 Therefore  $PN = \frac{1}{2}P$ .

Coroll. 3. The tangent of the vertex AH is a mean proportional between AF and AP. For since FHT is a right angle, therefore AH is a mean proportional between AF and AT; and since  $AT = AP$ , AH is a mean proportional between AF and AP. Also FH is a mean proportional between FA and FT, or between FA and FM.

Coroll. 4. The tangent makes equal angles with FM and the axis AP, as well as with FC and CI.

1102. THEOREM VII. *A line parallel to the axis, intercepted by a double ordinate and a tangent at the vertex of that ordinate, will be divided by the curve in the same ratio as the line itself divides the double ordinate.*

Let QM (fig. 451.) be the double ordinate, MT the tangent, AP the axis, GK the intercepted line divided by the curve in the point I; then will  $GI : IK :: MK : KQ$ .

For by similar triangles MKG, MPT;  $MK : KG :: PM : PT$ ,  
or  $2AP$ ;

By the definition of parameter,

$P : PM :: PM : 2AP$ ;

Therefore, by equality,

$P : MK :: PM : KG$ ;

And again, by equality,

$PM : MK :: 2AP : KG$ ;

And by division,

$MK : KQ :: GI : IK$ .

Fig. 451.

1103. PROBLEM I. *To describe a parabola.*

If a thread, equal in length to the leg BC (fig. 452.) of a right angle or square, be fixed to the end C, and the other end of the thread be fixed to a point F in a plane, then if the square be moved in that plane so that the leg AB may slide along the straight line GH, and the point D be always kept close to the edge BC of the square, and the two parts FD and DC of the string kept stretched, the point D will describe a curve on the plane, which will be a parabola.

Fig. 452.

1104. PROB. II. *Given the double ordinate DE and the abscissa BC in position and magnitude, to describe a parabola.*

Through B (figs. 453, 454.) draw FG parallel to DE and DF, and EG parallel to CD.

Fig. 453.

Divide DC and DF each into the same number of equal parts. From the points of division in DE draw lines to B.

Fig. 454.

Through the points of division in DC draw lines parallel to BC, and through the points of intersection of the corresponding lines draw a curve, and complete the other half in the same manner; then will DBE be the complete curve of the parabola. The less BC is in proportion to CD, the nearer the curve will approach to the arc of a circle, as in fig. 422.; and hence we may describe

the curve for diminishing the shaft of a column, or draw a flat segment of a circle.

1105. PROB. III. *The same parts being given, to describe the parabola by the intersection of straight lines.*

Produce CB to F (fig. 455.), and make BF equal to BC. Join FD and FE. Divide DF and FE in the same proportion, or into the same number of equal parts. Let the divisions be numbered from D to F, and from F to E, and join every two corresponding points by a straight line; then the intersection of all the straight lines will form the parabola required.

Fig. 455.

1106. PROB. IV. *To draw a straight line from a given point in the curve of a parabola, which shall be a tangent to the curve at that point.*

Let DC (fig. 456.) be the double ordinate, CB the abscissa to the parabolic curve DBC, and let it be required to draw a tangent from the point e in the curve. Draw ef parallel to DC, cutting BC in f; produce CB to g, and make Bg equal to Bf, and join ge, then will ge be the tangent required. In the same manner DH will be found to be a tangent at D. If eK be drawn perpendicular to the tangent ge, then will eK be also perpendicular to the curve, and in the proper direction for a joint in the masonry of a parabolic arch.

Fig. 456.

1107. The uses of the parabolic curve in architecture are many. The theorists say that it is the curve of equilibrium for an arch which has to sustain a load uniformly diffused over its length, and that therefore it should be included in the depth of lintels and flat arches; and that it is nearly the best form for suspension and other bridges, and for roofs. It is also considered the best form for beams of equal strength. It may be here also remarked, that it is the curve described by a projectile, and that it is the form in which a jet of water is delivered from an orifice made in the side of a reservoir. So is it the best curve for the reflection of light to be thrown to a distance. In construction it occurs in the intersection of conic surfaces by planes parallel to the side of the cone, and is a form of great beauty for the profiles of mouldings, in which manner it was much used in Grecian buildings.

GENERAL METHOD OF DETERMINING THE SPECIES AND OF DESCRIBING CONIC SECTIONS.

1108. In a conic section, let there be given the abscissa AB (*fig. 457.*), an ordinate BC, and a tangent CD to the curve at the extremity of the ordinate to determine the species of the conic section, and to describe the figure.

Draw AD parallel to BC, and join AC (Nos. 1. and 2.). Bisect AC in E, and produce DE and AB, so as to meet in F when DE is not parallel to AB; then in the case where DE will meet AB or AB produced in F, the point F will be the centre of an ellipsis or hyperbola. In this case produce AF to G, and make FG equal to FA; then if the ordinate BC and the centre be upon the same side of the apex A, the curve to which the given parts belong is an ellipsis; but if they be on different sides of it, the curve is an hyperbola. When the line DE (No. 3.) is parallel to AB, the figure is a parabola.

Fig. 457.

Fig. 458.

1109. In a conic section, the abscissa AB (*fig. 458.*), an ordinate BC, and a point D in the curve being given, to determine the species of the curve, and thence to describe it.

Draw CG parallel to AB (Nos. 1. and 2.), and AG parallel to BC. Join AD, and produce it to meet CG in e. Divide the ordinate CB in f in the same proportion as CG is divided, then will  $Cf : fB :: Ce : eG$ . Join Df, and produce it or fD to meet AB or BA in h; then if the points D and h fall upon opposite sides of the ordinate BC, the curve is an ellipsis; but if D and h fall upon the same side of the ordinate BC, the curve will be an hyperbola. If Df (No. 3.) be parallel to AB, the curve will be a parabola. In the case of the ellipsis and hyperbola, Ah is a diameter; and therefore we have a diameter and ordinate to describe the curve.

SECT. VI.

DESCRIPTIVE GEOMETRY.

1110. The term Descriptive Geometry, first used by Monge and other French geometers to express that part of the science of geometry which consists in the application of geometrical rules to the representation of the figures and the various relations of the forms of bodies, according to certain conventional methods, differs from common perspective by the design or representation being so made that the exact distance between the different points of the body represented can always be found; and thus the mathematical relations arising from its form and position may be deduced from the representation. Among the English writers on practical architecture, it has usually received the name of *projection*, from the circumstance of the different points and lines of the body being projected on the plane of representation; for, in descriptive geometry, points in space are represented by their orthographical projection on two planes at right angles to each other, called the *planes of projection*, one of which planes is usually supposed to be horizontal, in which case the other is vertical, the projections being called horizontal or vertical, according as they are on one or other of these planes.

1111. In this system, a point in space is represented by drawing a perpendicular from it to each of the planes of projection; the point whereon the perpendicular falls is the

projection of the proposed point. Then, as points in space are the boundaries of lines, so their projections similarly form lines, by whose means their projection is obtained; and by the projections of points lying in curves of any description, the projections of those curves are obtained.

1112. For obvious reasons, surfaces cannot be similarly represented; but if we suppose the surface to be represented, covered by a system of lines, according to some determinate law, then these lines projected on each of the two planes will, by their boundaries, enable us to project the surface in a rigorous and satisfactory manner.

1113. There are, however, some surfaces which may be more simply represented; for a plane is completely defined by the straight lines in which it intersects the two planes of projection, which lines are called the *traces* of the plane. So a sphere is completely defined by the two projections of its centre and the great circle which limits the projections of its points. So also a cylinder is defined by its intersection (or trace) with one of the planes of projection and by the two projections of one of its ends; and a cone by its intersection with one of the planes of projection and the two projections of its summit.

1114. Monge, before mentioned, Hachette, Vallée, and Leroi, are the most systematic writers on this subject, whose immediate application to architecture, and to the mechanical arts, and most especially to engineering, is very extensive; in consequence, indeed, of which it is considered of so much importance in France, as to form one of the principal departments of study in the Polytechnic School of Paris. A sufficient general idea of it for the architectural student may be obtained in a small work of Le Croix, entitled, *Complément des Elémens de Geometrie*. In the following pages, and occasionally in other parts of this work, we shall detail all those points of it which are connected more immediately with our subject, inasmuch as we do not think it necessary to involve the reader in a mass of scientific matter connected therewith, which we are certain he would never find necessary in the practice of the art whereon we are engaged.

1115. In order to comprehend the method of tracing geometrically the projections of all sorts of objects, we must observe,—I. That the visible faces only of solids are to be expressed. II. That the surfaces which enclose solids are of two sorts, rectilinear and curved. These, however, may be divided into three classes,—1st. Those included by plane surfaces, as prisms, pyramids, and, generally, similar sorts of figures used in building. 2d. Those included by surfaces whereof some are plane and others with a simple curvature, as cylinders, cones, or parts of them, and the *voussoirs* of arches. 3d. Solids enclosed by one or several surfaces of double flexure, as the sphere, spheroids, and the *voussoirs* of arches on circular planes.

1116. *First class, or solids with plane surfaces.*—The plane surfaces by which these solids are bounded form at their junction edges or *arriages*, which may be represented by right lines.

1117. And it is useful to observe in respect of solids that there are three sorts of angles formed by them. *First*, those arising from the meeting of the lines which bound the faces of a solid. *Second*, those which result from the concurrence of several faces whose edges unite and form the summit of an angle: thus a solid angle is composed of as many plane angles as there are planes uniting at the point, recollecting however that their number must be at least three. *Third*, the angles of the planes, which is that formed by two of the faces of a solid. A cube enclosed by six square equal planes comprises twelve rectilinear edges or *arriages* and eight solid angles.

1118. Pyramids are solids standing on any polygonal bases, their planes or faces being triangular and meeting in a point at the top, where they form a solid angle.

1119. Prisms, like pyramids, may be placed on all sorts of polygonal bases, but they rise on every side of the base in parallelograms instead of triangles, thus having throughout similar form and thickness.

1120. Though, strictly speaking, pyramids and prisms are polyhedrons, the latter term is only applied to those solids whose faces forming polygons may each be considered as the base of a separate pyramid.

1121. In all solids with plane surfaces the *arriages* terminate in solid angles formed by several of these surfaces, which unite with one another; whence, in order to find the projection of the right lines which represent those *arriages*, all that we require to know is the position of the solid angles where they meet; and as a solid angle is generally composed of several plane angles, a single solid angle will determine the extremity of all the *arriages* by which it is formed.

1122. *Second class: solids terminated by plane and curved surfaces.*—Some of these, as cones for instance, exhibit merely a point and two surfaces, one curved and the other flat. The meeting of these surfaces forms a circular or elliptical *arris* common to both. The projection of an entire cone requires several points for the curvature which forms its base, but a single point only is necessary to determine its summit. This solid may be considered as a pyramid with an elliptic or circular base; and to facilitate its projection a polygon is inscribed in the ellipsis or circle, which serves as its base.

1123. If the cone is truncated or cut off, polygons may in like manner be inscribed in the curves which produce the sections.

1124. Cylinders may be considered as prisms whose bases are formed by circles, ellipses, or other curves, and their projections may be obtained in a similar manner: that is, by inscribing polygons in the curves which form their bases.

1125. *Third class: solids whose surfaces have a double curvature.*—A solid of this sort may be enclosed in a single surface, as a sphere or spheroid.

1126. As these bodies present neither angles nor lines, they can only be represented by the apparent curve which seems to bound their superficies. This curve may be determined by tangents parallel to a line drawn from the centre of the solid perpendicularly to the plane of projection.

1127. If these solids are truncated or cut by planes, we must, after having traced the curves which represent them entire, inscribe polygons in each curve produced by the sections, in order to proceed as directed for cones and cylinders.

1128. To obtain a clear notion of the combination of several pieces, as, for instance, of a vault, we must imagine the bodies themselves annihilated, and that nothing remains but the arrises or edges which form the extremes of the surfaces of the voussoirs. The whole assemblage of material lines which would result from this consideration being considered transparent would project upon a plane perpendicular to the rays of light, *traces* defining all these edges that we have supposed material, some foreshortened, and others of the same size. These will form the outlines of the vault, whence follow the subjoined remarks.

- I. That in order, on a plane, to obtain the projection of a right line representing the arris of any solid body, we must on such plane let fall verticals from each of its extremities.
- II. That if the arris be parallel to the plane of the drawing, the line which represents its projection is the same size as the original.
- III. That if it be oblique, its representation will be shorter than the original line.
- IV. That perpendiculars by means of which the projection is made being parallel to each other, the line projected cannot be longer than the line it represents.
- V. That in order to represent an arris or edge perpendicular to the plane of projection, a mere point marks it because it coincides in the length with the perpendiculars of projection.
- VI. That the measure of the obliquity of an arris or edge will be found by verticals let fall from its extremities.

1129. In conducting all the operations relative to projections, they are referable to two planes, whereof one is horizontal and the other vertical.

# PROJECTION OF RIGHT LINES.

1130. The projection of a line AB (*fig. 459.*) perpendicular to a horizontal plane is ex-

Fig. 459.

Fig. 460.

Fig. 461.

Fig. 462.

pressed on such plane by a point K, and by the lines *ab*, *a'b'*, equal to the original on vertical planes, whatever their direction.

1131. An inclined line CD (*fig. 460.*) is represented on an horizontal or a vertical plane by *cd*, *c'd'*, shorter than the line itself, except on a vertical plane, parallel to its projection, on the horizontal plane *c''d''*, where it is equal to the original CD

1132. An inclined line EF (*fig. 461.*) moveable on its extremity E, may, by preserving the same inclination in respect of the plane on which it lies, have its projection successively in all the radii of the circle *Ef*, determined by the perpendicular let fall from the point F.

1133. Two lines GH, IK (*fig. 462.*), whereof one is parallel to an horizontal plane and the other inclined, may have the same projection *m*, *n*, upon such plane. Upon a vertical

plane perpendicular to  $mn$ , the projection of the line  $GH$  will be a point  $g$ ; and that of the inclined line  $IK$ , the vertical  $ik$ , which measures the inclination of that line. Lastly, on a vertical plane parallel to  $mn$ , the projection  $i'k'$  and  $g'h'$  will be parallel and equal to the original lines.

#### PROJECTION OF SURFACES.

1134. What has been said in respect of right lines projected on vertical and horizontal planes may be applied to plane surfaces; thus, from the surface  $ABCD$  (*fig. 463.*), parallel to an horizontal plane, results the projection  $abcd$  of the same size and form. An inclined surface  $EFGH$  may have, though longer, the same projection as the level one  $ABCD$ , if the lines of projection  $AE$ ,  $BF$ ,  $DH$ ,  $CG$  are in the same direction.

1135. The level surface  $ABCD$  would have for projection on vertical planes the right lines  $ab$ ,  $b'c'$ , because that surface is in the same plane as the lines of projection.

1136. The inclined surface  $EFGH$  will give on vertical planes the foreshortened figure  $hgef$  of that surface; and upon the other the simple line  $fq$ , which shows the profile of its inclination, because this plane is parallel to the side of the inclined surface.

Fig. 463.

#### PROJECTION OF CURVED LINES.

1137. Curve lines not having their points in the same direction occupy a space which brings them under the laws of those of surfaces. The projection of a curve on a plane parallel to the surface in which it lies (*fig. 464.*) is similar to the curve.

Fig. 464.

Fig. 465.

Fig. 466.

Fig. 467.

1138. If the plane of projection be not parallel, a foreshortened curve is the result, on account of its obliquity to the surface (*fig. 465.*).

1139. If the curve be perpendicular to the plane of projection, we shall have a line representing the profile of the surface in which it is comprised; that is to say, a right line if the surface lie in the same plane (*fig. 466.*), and a curved line if the surface be curved (*fig. 467.*).

1140. In order to describe the projection of the curve line  $ABC$  (*fig. 467.*), if the surface in which it lies is curved, and it is not perpendicular to the plane of projection, a polygon must be inscribed in the curve, and from each of the angles of such polygon a perpendicular must be let fall, and parallels made to the chords which subtend the arcs. But it is to be observed, that this line having a double flexure, we must further inscribe a polygon in the curvature which forms the plane  $abc$  of the surface wherein the curved line lies.

1141. The combination and developement of all the parts which compose the curved surfaces of vaults being susceptible of representation upon vertical and horizontal planes by right or curve lines terminating their surfaces, if what has been above stated be thoroughly understood, it will not be difficult to trace their projections for practical purposes, whatever their situation and direction in vaults or other surfaces.

PROJECTION OF SOLIDS.

1142. The projections of a cube  $ABCDEFGH$  placed parallel to two planes, one horizontal and the other vertical, are squares whose sides represent faces perpendicular to these planes (*fig. 468.*), which are represented by corresponding small letters.

Fig. 468.

Fig. 469.

1143. If we suppose the cube to move on an axis, so that two of its opposite faces remain perpendicular to the planes (*fig. 469.*), its projection on each will be a rectangle, whose length will vary in proportion to the difference between the side and the diagonal of the square. The motion of the opposite arrisses will, on the contrary, produce a rectangle whose width will be constant in all the dimensions contained of the image of the perfect square to the exact period when the two arrisses unite in a single right line.

1144. A cylinder (*fig. 470.*) stands perpendicularly on an horizontal plane, and on such

Fig. 470.

Fig. 471.

plane its projection  $ADBC$  is shown, being thereon represented by a circle, and upon a vertical plane by the rectangle  $gedh$ .

Fig. 472.

Fig. 473.

1145. The projection of an inclined cylinder (*fig. 471.*) is shown on a vertical and horizontal plane.

1146. In *fig. 472.* we have the representation of a cube doubly inclined, so that the diagonal from the angle B to the angle G is upright. The projection produced by this position upon an horizontal plane is a regular hexagon *acbefg*, and upon a vertical plane the rectangle *Begc* whose diagonal *Bg* is upright; but as the effect of perspective changes the effect of the cube and its projections, it is represented geometrically in *fig. 473.*

1147. In *figures 474. and 475.* a pyramid and cone are represented with their projects on horizontal and vertical planes.

1148. *Fig. 476.* represents a ball or sphere with its projections upon two planes, one

Fig. 471.

Fig. 475.

Fig. 476.

vertical and the other horizontal, wherein is to be remarked the perfection of this solid, seeing that its projection on a plane is always a circle whenever the plane is parallel to the circular base formed by the contact of the tangents.

#### DEVELOPEMENT OF SOLIDS WHOSE SURFACES ARE PLANE.

1149. We have already observed that solids are only distinguished by their apparent faces, and that in those which have plane surfaces, their faces unite so as to form solid angles. We have also observed that at least three plane angles are necessary to form a solid angle; whence it is manifest that the most simple of all the solids is a pyramid with a triangular base, which is formed by four triangles, whereof three are united in the angles at its apex. (*Fig. 477.*)

1150. The development of this solid is obtained by placing on the sides of the base,

Fig. 478.

Fig. 479.

Fig. 480.

Fig. 481.

Fig. 482.

the three triangles whose faces are inclined (*fig. 478.*); by which we obtain a figure composed of four triangles. To cut this out in paper, for instance, or any other flexible material, after bending it on the lines *ab*, *bc*, *ac*, which form the triangle at the base, the three triangles are turned up so as to unite in the summit.

#### DEVELOPEMENT OF REGULAR POLYHEDRONS.

1151. The solid just described formed of four equal equilateral triangles, as we have seen, is the simplest of the five regular polyhedrons, and is called a *tetrahedron*, from its being composed of four similar faces. The others are —

The *hexahedron*, or cube whose faces are six in number ;  
 The *octahedron*, whose faces are eight equilateral triangles ;  
 The *dodecahedron*, whose faces are twelve regular pentagons ;  
 The *icosahedron*, consisting of twenty equilateral triangles.

These five regular polyhedrons are represented by the *figures* 477. 479, 490, 481, and 482., and their developement by the *figures* 478. 483, 484, 485, and 486.

1152. The surfaces of these developements are so arranged as to be capable of being united by moving them on the lines by which they are joined.

1153. It is here proper to remark, that the equilateral triangle, the square, and the pentagon, are the only figures which will form regular polyhedrons whose angles and sides are equal ; but by cutting in a regular method the solid angles of these polyhedrons, others regularly symmetrical may be formed whose sides will be formed of two similar figures. Thus, by cutting in a regular way the angles of a tetrahedron, we obtain a polyhedron of eight faces, composed of four hexagons and four equilateral triangles. Similarly operating on the cube, we shall have six octagons, connected by eight equilateral triangles, forming a polyhedron of fourteen faces.

1154. The same operation being performed on the octahedron also gives a figure of fourteen faces, whereof eight are octagons and six are squares.

1155. The dodecahedron so cut produces twelve pentagons united by twenty hexagons, and having thirty-two sides. This last, from some points of view, so approaches the figure of the sphere, that, at a little distance, it looks almost spherical.

#### DEVELOPEMENT OF PYRAMIDS AND PRISMS.

1156. The other solids whose surfaces are plane, whereof mention has already been made, are pyramids and prisms, partaking of the tetrahedron and cube ; of the former, inasmuch as their sides above the base are formed by triangles which approach each other so as together to form the solid angle which is the summit of the pyramid ; of the latter, because their faces, which rise above the base, are formed by rectangles or parallelograms which preserve the same distance from each other, but differ, from their rising on a polygonal base and being undetermined as to height.

1157. This species may be regular or irregular, they may have their axes perpendicular or inclined, they may be truncated or cut in a direction either parallel or inclined to their bases.

1158. The developement of a pyramid or right prism, whose base and height are given, is not attended with difficulty. The operation is by raising on each side of the base a triangle equal in height to the inclined face, as in the pyramidal figures 487. and 488., and a rectangle equal to the perpendicular height if it be a prism.

#### DEVELOPEMENT OF AN OBLIQUE PYRAMID.

1159. If the pyramid be oblique, as in *fig.* 489., wherein the length of the sides of each triangle can only be represented by foreshortening them in a vertical or horizontal projection, a third operation is necessary, and that is founded on a principle common to all projections ; viz. that the length of an inclined line projected or foreshortened on a plane, depends upon the difference of the perpendicular elongation of its extremities from the plane,

whence in all cases a rectangular triangle, whose vertical and horizontal projections give two sides, the third, which is the hypotenuse, joining them, will express the length of the foreshortened line.

1160. In the application of this rule to the oblique pyramid of *fig. 489.*, the position of the point P (*fig. 490.*) must be shown on the plan or horizontal projection answering to the apex of the pyramid, and from this point perpendicular to the face CD on the same side the perpendicular PG must be drawn. Then from the point P as a centre describe the arcs Bb, Cc, which will transfer upon PG the horizontal projections of the inclined arrisses AP, EP, and DP; and raising the perpendicular PS equal to the height of the apex P of the pyramid above the plane of projection, draw the lines Sa, Sb, Sc, which will give the real lengths of all the edges or arrisses of the pyramid.

1161. We may then obtain the triangles which form the development of this pyramid, by describing from C as a centre with the radius Sc, the arc *ig*, and from the point D another arc intersecting the other in F. Drawing the lines CF, DF, the triangles CFD will be the development of the side DC. To obtain that answering to BC, from the points F and C with Sb and Bc as radii, describe arcs intersecting in B' and draw B'F and CB': the triangle FCB' will be the development of the face answering to the side Bc.

1162. We shall find the triangle FA'B', by using the lengths SA and BA to find the points B' and F, which will determine the triangle corresponding to the face AB, and lastly the triangles FDE' and FE'A'' corresponding to the faces DE, AE by using the lengths Sb, DE and SA, AE. The whole development AEDE'A''F, A'B', CBA being bent on the lines BFcF, CD, DF, and EF will form the inclined figure represented in *fig. 489.*

1163. If this pyramid be truncated by the plane *mn*, parallel to the base, the contour resulting from the section may be traced on the development by producing Pm from F to *a*, and drawing the lines *ab, bc, cd, de* and *ea''* parallel to A'B', B'C, CD, DE' and E'A''.

1164. But if the plane of the section be perpendicular to the axis, as *mo*, from the point F with a radius equal to Po describe an arc of a circle, in which inscribe the polygon *ab''c'd'e''a''*. Then the polygon *oqmq'o'* is the plane of the section induced by the line *mo*.

#### DEVELOPEMENT OF RIGHT AND OBLIQUE PRISMS.

1165. In a right prism, the faces being all perpendicular to the bases which terminate the solid, the developments are rectangles, consisting of all these faces joined together and enclosed by two parallel right lines equal to the contours of the bases.

1166. When a prism is inclined, the faces form different angles with the lines of the contours of the bases, whence results a development whose extremities are terminated by lines forming portions of polygons.

1167. We must first begin by tracing the profile of the prism parallel to its degree of inclination (*fig. 491.*). Having drawn the line Cc, which represents the inclined axis of the prism in the direction of its length, and the lines AD, *bd*, to show the surfaces by which it is terminated, describe on such axis the polygon which forms the plane of the prism *h, i, k, l, m* perpendicular to the axis. Producing the sides *kl, hn* parallel to the axis to meet the lines AD, *bd*, they will give the four arrisses of the prism, answering to the angles *h, n, k, l*; and the line Cc which loses itself in the axis will give the arrisses *im*.

1168. It must be observed, that in this profile the sides of the polygon *h, i, k, l, m* give the width of the faces round the prism, and the lines Ab, Cc, Dd their length. From this profile follows the horizontal projection (*fig. 492.*) wherein the lengthened polygons repre-

sent the bases of the prism. In order to obtain the developement of this inclined prism, so that being bent up it may form the figure, from the middle of  $Cc$ , *fig. 491.* a perpendicular  $o, p, q$  must be raised, produced to  $l, l'$ , *fig. 493.*; on this line must be transferred the widths of the faces shown by the polygon  $h, i, k, l, m, n$ , of *fig. 491.* in  $l, k, i, h, n, m, l'$ , *fig. 493.*; through these points parallel to the axis, lines are to be drawn, upon which  $qD$  of *fig. 491.* must be laid from  $l$  to  $E$ , from  $k$  to  $D$ , and from  $l'$  to  $E'$ , *fig. 493.*;  $pC$ , *fig. 491.*, must be laid from  $i$  to  $C$ , and from  $m$  to  $F$  in *fig. 493.*

$oA$ , *fig. 491.*, is to be laid from  $h$  to  $B$  and from  $n$  to  $A$ , *fig. 493.*, which will give the contour of the developement of the upper part by drawing the lines  $ED$ ,  $DCB$ ,  $BA$ ,  $AFE'$ , *fig. 492.*

To obtain the contour of the base,  $qd$  of *fig. 491.* must be transferred from  $l$  to  $q$ , from  $k$  to  $d$ , and from  $l'$  to  $e'$ , *fig. 493.*

$pc$  from *fig. 491.* from  $i$  to  $c$  and from  $m$  to  $f$  (*fig. 493.*); lastly,  $ob$  of *fig. 16.* must be transferred from  $h$  to  $b$  and from  $n$  to  $a$  (*fig. 493.*) and drawing the lines  $ed$ ,  $bed$ ,  $ba$ , and  $afe'$ , the contour will be obtained.

1169. The developement will be completed by drawing on the faces  $BA$  and  $ba$ , elongated polygons similar to  $ABCDEF$  and  $abcdef$  of *fig. 491.* and of the same size.

#### DEVELOPEMENT OF RIGHT AND OBLIQUE CYLINDERS.

1170. Cylinders may be considered as prisms whose bases are formed by polygons of an infinite number of sides. Thus, graphically, the developement of a right cylinder is obtained, by a rectangle of the same height, having in its other direction the circumference of the circle which serves as its base measured by a greater or less number of equal parts.

1171. But if the cylinder is oblique (*fig. 494.*), we must take the same measures as for

the prism, and consider the inclination of it. Having described centrally on its axis the circle or ellipsis which forms its perpendicular thickness in respect of the axis, the circumference must be divided into an equal number of equal parts, as, for instance, twelve, beginning from the diameter and drawing from the points of division the parallels to the axis  $HA, bi, ck, dl, em, fm, GO$ , which will give the projection of the bases and the general developement.

1172. For the projection of the bases on an horizontal plane, it is necessary that from the points where the parallels meet the line of the base  $HO$ , indefinite perpendiculars should be let fall, and after having drawn the line  $H'O'$ , parallel to  $HO$ , upon these perpendiculars above and below the parallel must be transferred the size of the ordinates of

the circle or ellipsis traced on the axis of the cylinder, that is,  $p1$  and  $p10$  to  $i'1$ , and  $i'10$  :  $q2$  and  $q9$  in  $k'2$  and  $k'q$ , &c. In order to avoid unnecessary repetition, the *figs.* 494, 495, 496. are similarly figured, and will by inspection indicate the corresponding lines.

1173. In the last figure the line  $E'E'$  is the approximate development of the circumference of the circles which follow the section  $DE$  perpendicular to the axis of the cylinder, divided into 12 equal parts, *fig.* 494. For which purpose there have been transferred upon this line on each side of the point  $D$ , six of the divisions of the circle, and through these points have been drawn an equal number of indefinite parallels to the lines traced upon the cylinder in *fig.* 494 : then taking the point  $D'$  as correspondent to  $D$ , the length of these lines is determined by transferring to each of them their relative dimensions, measured from  $DG$  in  $AG$  for the superior surface of the cylinder, and from  $DE$  to  $HO$  for the base.

1174. In respect of the two elliptical surfaces which terminate this solid, what has been above stated, on the manner of describing a curve by means of ordinates, will render further explanation on that point needless.

#### DEVELOPEMENT OF RIGHT AND OBLIQUE CONES.

1175. The reasoning which has been used in respect of cylinders and prisms, is applicable to cones and pyramids.

1176. In right pyramids, with regular and symmetrical bases, the edges or arrisses from the base to the apex are equal, and the sides of the polygon on which they stand being equal, their development must be composed of similar isosceles triangles, which in their union will form throughout, part of a regular polygon, inscribed in a circle whose inclined sides will be the radii. Thus, in considering the base of the cone  $A'B'$  (*fig.* 497.) as a

regular polygon of an infinite number of sides, its development becomes a sector of a circle  $A'B''B'''C'$  (*fig.* 498.) whose radius is equal to the side  $A'C'$  of the cone, and the arc equal to the circumference of the circle which is its base.

1177. Upon this may be traced the development of the curves which would result from the cone cut according to the lines  $DI$ ,  $EF$ , and  $GH$ , which are the ellipsis, the parabola, and the hyperbola. For this purpose the circumference of the base of the cone must be divided into equal parts; from each point lines must be drawn to the centre  $C$ , representing in this case the apex of the cone. Having transferred, by means of parallels, to  $FF$ , the divisions of the semi-circumference  $AFB$  of the plan, upon the line  $A'B'$ , forming the base of the vertical projection of the cone (*fig.* 497.) to the points  $1'2'$ ,  $F'3'$ , and  $4'$ , which, because of the uniformity of the curvature of the circle will also represent the divisions on the plan marked 8,  $7F'$ , 6, and 5; from the summit  $C'$  in the elevation of the cone, the lines  $C'1'$ ,  $C'2'$ ,  $C'F'$ ,  $C'3'$ ,  $C'4'$  are to be drawn, cutting the plans  $DI$ ,  $EF$ , and  $GH$  of the ellipse, of the parabola, and of the hyperbola; then by the assistance of these intersections their figures may be drawn on the plan, the first in  $D'p'I'p'$ ; the second in  $FE'F'$ ; the third in  $H'GH'$ .

1178. To obtain the points of the circumference of the ellipse upon the development (*fig.* 498.) from the points  $n$ ,  $o$ ,  $p$ ,  $q$ ,  $r$  of the line  $DI$  (*fig.* 497.), draw parallels to the base for the purpose of transferring their heights upon  $C'B'$  at the points 1, 2, 3, 4, 5. Then transfer  $C'D$  upon the development, in  $C''n''$ ,  $C''o''$ ,  $C''p''$ ,  $C''q''$ ,  $C''r''$ ; and in the same order below,  $C''n'''$ ,  $C''o'''$ ,  $C''p'''$ ,  $C''q'''$ ,  $C''r'''$ ; and  $CI$  from  $C''$  in  $I''$  and  $I'''$ . The

curve passing through these points will be the development of the circumference of the ellipse indicated in *fig. 497.* by the right line *DI*, which is its great axis.

1179. For the parabola (*fig. 499.*) on the side *C'A'* (*fig. 497.*), draw *bg* and *ah*; then transfer *C'E* on the development in *C''E''*; *C'g* from *C''* to *b'''* and *b''''*; *C'h*, from *C''* to *a'''* and *a''''*; and through the points *F''*, *a'''*, *b'''*, *E''*, *b''''*, *a''''*, *F'''*, trace a curve, which will be the development of the parabola shown in *fig. 497.* by the line *EF*.

1180. For the hyperbola, having drawn through the points *m* and *i*, the parallels *me*, *if*, transfer *C'G* from *C''* to *G''*, and from *C''* to *G'''* of the development, *C'e* from *C''* to *m''* and *m'''*, *C'f* from *C''* to *i'''* and *i''''*; and after having transferred *3H'* and *6H''* of the plan to the circumference of the development, from *3* to *H'''*, and from *6* to *H''''*, by the aid of the points *H'''*, *i'''*, *m'''*, *G'''* and *H''''*, *i''''*, *m''''*, *G''''*, draw two curves, of which each will be the development of one half of the hyperbola represented by the right lines *GH* and *H'H'*, *figs. 497.* and *500.*, and by *fig. 501.*

1181. The mode of finding the development of an oblique cone, shown in *figs. 502, 503,*

504, 505. differs, as follows, from the preceding. 1. From the position of the apex *C* upon the plan 503., determined by a vertical let fall from such apex in *fig. 502.* 2. Because the line *DI* of this figure, being parallel to the base, gives for the plan a circle instead of an ellipsis. 3. Because in finding the lengthened extent of the right lines drawn from the apex of the cone to the circumference of the base, divided into equal parts, *fig. 504.* is introduced to bring them together in order to avoid confusion, these lines being all of a different size on account of the obliquity of the cone. In this figure the line *CC'* shows the perpendicular height of the apex of the cone above the plan; so that by transferring from each side the projections of these lines taken on the plan from the point *C* to the circumference, we shall have *CA'*, *C1*, *C2*, *CF'*, *C3*, *C4*, *CB'*, on one side, and *CA'*, *C8*, *C7*, *CF*, *C6*, *C5*, and *CB''* on the other; lastly, from the point *C* drawing lines to all these points, they will give the edges or arrisses of the inscribed pyramid, by which the development in *fig. 505.* is obtained. Having obtained the point *C''* representing the apex, a line is to be drawn through it equal to *CA''* (*fig. 504.*); then with one of the divisions of the base taken on the plan, such as *A1*, it must be laid from the point *A* of the development of the section; then taking *C'1* of *fig. 504.*, describe from the point *C''* another arc which will cross the former, and will determine the point *1* of the development. Continuing the operations with the constant length *A1* and the different lengths *C2*, *CF'*, *C3*, &c., taken from *fig. 504.* and transferred to *C'2*, *C'F*, *C'3*, &c. of the development, the necessary points will be obtained for tracing the curve *B''AB'''*, representing the contour of the oblique base of the cone.

1182. We obtain the development of the circle shown by the line *DI* of *fig. 502.* parallel to that of the base *AB*, by drawing another line *I'D'D'I''* (*fig. 504.*) at the same distance from the summit *C*, cutting all the oblique lines that have served for the preceding development; and on one side, *CD''*, *Cn*, *Co*, *Cp*, *Cq*, *Cr*, *CI'*, must be carried to *fig. 505.*, from *C''* to *D''*, *n*, *o*, *p*, *q*, *r*, and on the other from *C''* to *n*, *o*, *p*, *q*, *r*, and *I'''*, on *fig. 505.* The curve line passing through these points will be the development of this circle.

1183. To trace upon the development the parabola and hyperbola shown by the lines *EF*, *G3* of *fig. 502.*, from the points *Ela*, *Gmi* draw parallels to the base *AB*, which, transferred to *fig. 504.*, will indicate upon corresponding lines the real distance of these points from the apex *C*, which are to be laid in *fig. 505.* from *C''* to *E*, *b*, *a*, *b* and *a* for

the parabola; and from  $C''$  to  $G, m, i$  on one side, and on the other to  $G, m, i$ , for the hyperbola. Each of these is represented in *figs.* 506. and 507.

DEVELOPEMENT OF BODIES OR SOLIDS WHOSE SURFACES HAVE A DOUBLE CURVATURE.

1184. The developement of the sphere and other bodies whose surface has a double flexure would be impossible, unless we considered them as consisting of a great number of plane faces or of simple curvatures, as the cylinder and the cone. Thus a sphere or spheroid may be considered, — I. As a polyhedron of a great number of plane faces formed by truncated pyramids whose base is a polygon, as *fig.* 508. II. By truncated cones, forming zones, as in *fig.* 509. III. By parts of cylinders cut in gores, forming flat sides that diminish in width, shown by *fig.* 510.

1185. In reducing the sphere or spheroid to a polyhedron with flat faces, the developement may be accomplished in two ways, which differ only by the manner in which the faces are developed.

1186. The most simple method of dividing the sphere to reduce it to a polyhedron is that of parallel circles crossed by others perpendicular to them, and intersecting in two opposite points, as in the common geographical globes. If, instead of the circle, the polygons are supposed of the same number of sides, a polyhedron will be the result, similar to that represented by *fig.* 508., whose half  $ADB$  shows the geometrical elevation, and  $AEB$  the plan of it.

Fig. 509.

Fig. 510.

1187. For the developement, produce  $A1, 12, 23$ , so as to meet the produced axis  $CP$  in order to obtain the summits  $P, q, r, D$  of the truncated pyramids which form the semi-polyhedron  $ADB$ ; then from the points  $P, q, r$ , with the radii  $PA, P1, q1, q2, r2, r3$  and  $D3$ , describe the indefinite arcs  $AB', 1b', 1b'', 2f', 2f'', 3g'$ , and  $3g$ , upon which, after having transferred the divisions of the demi-polygons  $AEB, 1e6''', 2e5''', 3e'', 4''$ , from all the transferred points, as  $A, 4', 5', 6', 7', 8', 9', B'$ , for each truncated pyramid draw lines to the summits  $PqrD$ , and other lines which will form inscribed polygons in each of the arcs  $AB', 1b', 1b'', \&c.$  These lines will represent for each band or zone the faces of the truncated pyramids whereof they are part.

1188. We may arrive at the same developement by raising upon the middle of each side of the polygon  $AEB$  indefinite perpendiculars, upon which must be laid the height of the faces of the elevation in  $1, 2, 3, 4$ ; through which points draw parallels to the base, upon which transfer the widths of each of the faces taken on the plan, whereby trapezia will be formed, and triangles similar to those found in the first developement, but ranged in another manner. This last developement, which is called in *gores*, is more suitable for geographical globes; the other method, for the formation of the centres, moulds, and the like, of spherical vaults.

1189. The developement of the sphere by conic zones (*fig.* 509.) is obtained by the same process as that by truncated pyramids, the only difference being, that the developement of the arrisses  $AB, 1b, 2f, 3g$ , are arcs of circles described from the summits of cones, instead of being polygons.

1190. The developement of the sphere reduced to portions of cylinders cut in gores (*fig.* 510.) is conducted in the second manner, but instead of joining with lines the points  $b, i, k, d$ , (*fig.* 508.) they must be united by a curve. This last method is useful in drawing the caissons or pannels in spherical or spheroidal vaults.

OF THE ANGLES OF PLANES OR SURFACES BY WHICH SOLIDS ARE BOUNDED.

1191. In considering the formation of solids, we have already noticed three sorts of angles, viz. plane angles, solid angles, and the angles of planes. The two first have been

treated of in the preceding sections, and we have now to speak of the third, which must not be confounded with plane angles. Of these last, we have explained that they are formed by the lines or arrisses which bound the faces of a solid; but the angles of planes, whereof we are about to speak, are those formed by the meeting of two surfaces joining in an edge.

1192. The inclination of one plane ALDE to another ALCB (*fig. 511.*) is measured by two perpendiculars FG, FH raised upon each of these planes from the same point F of the line or arris AL formed by their union.

1193. It is to be observed, that this angle is the greatest of all those formed by lines drawn from the point F upon these two planes; for the lines FG, FH being perpendicular to AL, common to both the planes, they will be the shortest that can be drawn from the point F to the sides ED, BC, which we suppose parallel to AL; thus their distance GH will be throughout the same, whilst the lines FI, FK will be so much the longer as they extend beyond the perpendiculars FG, FH, and we shall always have KI equal to GH, and consequently the angle IFK so much smaller than GFH as it is more distant.

1194. Thus, let a rectangular surface be folded perpendicularly to one of its sides so that the contours of the parts separated by the fold may fall exactly on each other. If we raise one of them, so as to move it on the fold as on a hinge, and so as to make it form all degrees of angles, we shall see that each of the central extremities of the moveable part is always in a plane perpendicular to the part that is fixed.

1195. This property of lines moving in a perpendicular plane, furnishes a simple method of finding the angles of planes of all sorts of solids whose vertical and horizontal projections or whose developements are known.

1196. Thus, in order to find the angles formed by the tetrahedron or pyramid on a triangular base (*fig. 477.*), we must for the angles of the base with the sides, let fall from the angles ABC perpendiculars to the sides *ac*, *cb*, and *ab*, which meet at the centre of the base in D. It is manifest from what has just been said on this subject, that if the three triangles are made to move, their angles at the summit A, B, C will not be the vertical planes shown by the lines AD, DB, DC, and that they will meet at the extremity of the vertical, passing through the intersection of these planes at the point D. Thus we obtain for each side a rectangular triangle, wherein two sides are known, namely, for the side *cb*, the hypotenuse *ed*, and the side *eD*. Thus raising from the point D an indefinite perpendicular, if from the point *e* with *eB* for a radius an arc is described cutting the perpendicular in *d*, and the line *de* be drawn, the angle *deD* will be that sought, and will be the same for the three sides if the polyhedron be regular; otherwise, if it is not, the operation must be repeated for each.

1197. These angles may be obtained with great accuracy by taking *de*, or its equal *eB*, for the whole sine; then *de* : *eD* :: sine : sine  $19^{\circ} 28'$ , whose complement  $70^{\circ} 32'$  will, if the polyhedron be regular, be the angle sought. In this case, all the sides being equal, and each being capable of serving as base, the angles throughout are equal. In respect of the cube (*figs. 479. and 483.*) whose faces are composed of equal squares, and whose angles are all right angles, it is evident that no other angles can enter into their combination with each other.

1198. To obtain the angle formed by the faces of the octahedron (*fig. 480.*) from the points C and D: with a distance equal to a vertical dropped upon the base of one of the triangles of its developement (*fig. 484.*), describe arcs crossing each other in F; and the angle CFD will be equal to that formed by the faces of the polyhedron, and will be found by trigonometry to be  $70^{\circ} 32'$ . In the dodecahedron (*fig. 481.*), the angle formed by the faces will be found by drawing upon its projection the lines DA, and producing the side B to E, determined by an arc made from the point D with a radius equal to BA. The angle sought will be found to be 108 degrees.

1199. For the icosahedron (*fig. 482.*), draw the parallels Aa, Bb, Cc, and after having made *bc* parallel and equal to BC, with a radius equal thereto, describe an arc cutting in *a* the parallel drawn from the point A; the angle *abc* will be equal to that formed by the sides of the polygon, which by trigonometry is found to be 108 degrees, as in the dodecahedron.

1200. For the pyramid with a quadrangular base (*fig. 487.*) the angle of each face with the base is equal to PAB or PBA, because this figure, which represents its vertical projection, is in a plane parallel to that within which will be found the perpendiculars dropped from the summit on the lateral faces of the base.

1201. In order to obtain the angles which the inclined sides form with one another, draw upon the developement (*fig. 488.*) the line ED, which, because the triangles PEC, PCD are equal and isosceles, will be perpendicular to the line PC, representing one of the arrisses which are formed. Then from the point D with a radius equal to DF, and

Fig. 511.

from the point C with a radius equal to the diagonal AD (of the square representing the square of the base) describe arcs intersecting each other. The angle FDG will be the angle sought. We may suppose it taken along the line BC traced in *fig. 487*.

1202. In order to obtain the angles formed by the faces of an oblique pyramid (*fig. 489.*), through some point *g* of the axis draw the perpendicular *mo*, showing the base *ogmq'o'* of the right pyramid *mpo*, whose developement is shown in *fig. 490.*, by the portion of the polygon *a, b'', c'', e'', d'', a'F*.

1203. By means of this base and the part developed, proceeding as we have already explained for the right pyramid, we shall find the angles formed by the meeting of the faces, and they will differ but little from those of the little polygon *ogmq'o'*.

1204. In respect to the angles formed by the faces inclined to the base, that of the face answering to the side *De* of the base is expressed by the angle *ADP* of the vertical projection, *fig. 489*.

1205. As to the other faces, for instance, that which corresponds to the side *AE* of the base (*fig. 490.*), through any point *g* draw *gf* perpendicular to it, meeting the line *AF*, showing the projection of one of the sides of the inclined face; upon the developement of this face, expressed by *A'E'F*, raise at the same distance from the point *E'* another perpendicular *g'm'*, which will give the prolongation of the line shown on the base by *Af*. If we transfer *A'm'* of the developement upon *Am*, which expresses the inclination of the arris represented by this line, we shall have the perpendicular height *mf* of the point *m* above the base, which, being transferred from *fm'* upon a perpendicular to *gf*, we shall have the two sides of a triangle whose hypotenuse *gm''* will give *m'gf*, the angle sought.

1206. In the oblique prism (*fig. 491.*), the angles of the faces are indicated by the plane of the section perpendicular to the axis, represented by the polygon *hiklmn*.

1207. Those of the sides perpendicular to the plan of the inclination of the axis are expressed by the angles *Ddb, Abd* of the profile in the figure last named.

1208. In order to obtain the angles formed with the other sides, for instance *CcDd* and *CcAb*, draw the perpendiculars *csbt*, whose projection in plan are indicated by *s'e'* and *b't'*, then upon *fc*, drawn aside, raise a perpendicular *c'e''* equal to *cs* of the profile, *fig. 491*. Through the point *c''* draw a line parallel to *fc*, upon which, having transferred *c's'* of the projection in plan (*fig. 492.*), draw the hypotenuse *s'e''*, and it will give the angle *s'e''f* formed by the face *CcDd* with the inferior base.

1209. To obtain the angles of the face *CcAb*, raise upon *Fb''*, drawn on one side, a perpendicular *b't''*, equal to *bt* (*fig. 492.*), and drawing as before a parallel to *b''* through the point *t''*, transfer *b't'* of *fig. 492.* to *t''t''*; and drawing *t'b''*, the angle *t'b''F* is that required.

1210. As the bases of this prism are parallel, these faces necessarily form the same angles with the superior base.

1211. An acquaintance with the angles of planes is of the greatest utility in the preparation of stone, and a thorough acquaintance with it will well repay the architectural student for the labour he may bestow on the subject.

## SECT. VII.

### MENSURATION.

1212. The area of a plane figure is the measure of its surface or of the space contained within its extremities or boundaries, without regard to thickness. This area, or the content of the plane figure, is estimated by the number of small squares it contains, the sides of each whereof may be an inch, a foot, a yard, or any other fixed quantity. Hence the area is said to consist of so many square inches, feet, yards, &c., as the case may be.

1213. Thus if the rectangle to be measured be *ABCD* (*fig. 512.*), and the small square *E*, whose side we will suppose to be one inch, be the measuring unit proposed; then, as often as such small square is contained in the rectangle, so many square inches are said to be contained in the rectangle. Here it will be seen by inspection that the number is 12; that the side *DC* or *AB*, which is 4 times the length of the measuring unit, multiplied by the number of times 3, which the length of the measuring unit is contained in *AD* or *BC*, will give 12 for the product.

1214. PROBLEM I. To find the area of a parallelogram, whether it be a square, a rectangle, a rhombus, or a rhomboid.

Multiply the length by the perpendicular breadth or height, and the product will be the area.

Fig. 512.

**Example 1.** Required the area of a parallelogram whose length is 12.25 feet, and height 8.5 feet.

$$12.25 \times 8.5 = 104.125 \text{ feet, or } 104 \text{ feet } 1\frac{1}{2} \text{ inches.}$$

**Example 2.** Required the content of a piece of land in the form of a rhombus whose length is 6.20 chains, and perpendicular height 5.45.

Recollecting that 10 square chains are equal to a square acre, we have,

$$6.20 \times 5.45 = 33.79 \text{ and } \frac{33.79}{10} = 3.379 \text{ acres, which are equal to 3 acres, 1 rood, } 20\frac{64}{100} \text{ perches.}$$

**Example 3.** Required the number of square yards in a rhomboid whose length is 37 feet, and breadth 5 feet 3 inches ( $= 5.25$  feet).

Recollecting that 9 square feet are equal to 1 square yard, then we have

$$37 \times 5.25 = 194.25, \text{ and } \frac{194.25}{9} = 21.584 \text{ yards.}$$

#### 1215. PROBLEM II. To find the area of a triangle.

**Rule 1.** Multiply the base by the perpendicular height, and take half the product for the area. Or multiply either of these dimensions by half the other. The truth of this rule is evident, because all triangles are equal to one half of a parallelogram of equal base and altitude. (See Geometry, 904.)

**Example 1.** To find the area of a triangle whose base is 625 feet, and its perpendicular height 520 feet. Here,

$$625 \times 520 = 162500 \text{ feet, the area of the triangle.}$$

**Rule 2.** When two sides and their contained angle are given: multiply the two given sides together, and take half their product; then say, as radius is to the sine of the given angle, so is half that product to the area of the triangle. Or multiply that half product by the natural sine of the said angle for the area. This rule is founded on proofs which will be found in Chap. IV., on which it is unnecessary here to say more.

**Example.** Required the area of a triangle whose sides are 30 and 40 feet respectively, and their contained angles  $28^\circ 57'$ .

By natural numbers: —

$$\text{First, } \frac{1}{2} \times 40 \times 30 = 600.$$

$$\text{Then, } 1 : 600 :: .484046 (\sin. 28^\circ 57') : 290.4276.$$

By logarithms: —

$$\sin. 28^\circ 57' = 9.684887$$

$$\text{Log. of } 600 = 2.778151$$

$$2.463038 = 290.4276, \text{ as above.}$$

**Rule 3.** When the three sides are given, take half the sum of the three sides added together. Then subtract each side severally from such half sum, by which three remainders will be obtained. Multiply such half sum and the three remainders together, and extract the square root of the last product, which is the area of the triangle. This rule is founded on one of the theorems in Trigonometry to be found in the section relating to that branch of the subject.

**Example.** Required the area of a triangle whose three sides are 20, 30, and 40.

$$20 + 30 + 40 = 90, \text{ whose half sum is } 45.$$

$$45 - 20 = 25, \text{ first remainder; } 45 - 30 = 15, \text{ second remainder; } 45 - 40 = 5, \text{ third remainder.}$$

$$\text{Then, } 45 \times 25 \times 15 \times 5 = 84375, \text{ whose root is } 290.4737, \text{ area required.}$$

#### 1216. PROBLEM III. To find the area of a trapezoid.

Add together the parallel sides, multiply their sum by the perpendicular breadth or distance between them, and half the product is the area. (See Geometry, 932.)

**Example 1.** Required the area of a trapezoid whose parallel sides are 750 and 1225, and their vertical distance from each other 1540.

$$1225 + 750 \times 770 = 1520750, \text{ the area.}$$

**Example 2.** Required the area of any quadrangular figure (*fig. 513.*) wherein

AP is 110 feet,

AQ 745 feet,

AB 1110 feet,

CP 352 feet,

DQ 595 feet.

Fig. 513.

$$\text{Therefore, } QB = AB - AQ = 1110 - 745 = 365,$$

$$\text{And } PQ = AB - AP - QB = 1110 - 110 - 365 = 635.$$

For PCDQ,  $595 + 352 \times 635 \div 2 = 300672.5$

For the triangle ACP,  $176 \times 110 = 19360$

For the triangle DQB,  $\frac{365 \times 595}{2} = 108587.5$

Area = 428620.0 feet.

1217. PROBLEM IV. *To find the area of any trapezium.*

Divide the trapezium into two triangles by a diagonal; then find the areas of the two triangles, and their sum is the area.

Observation. If two perpendiculars be let fall on the diagonal from the other two opposite angles, then add these two perpendiculars together, and multiply that sum by the diagonal. Half the product is the area of the trapezium.

Example. Required the area of a trapezium whose diagonal is 42, and the two perpendiculars on it 16 and 18.

Here,  $16 + 18 = 34$ , whose half = 17;

Then,  $42 \times 17 = 714$ , the area.

1218. PROBLEM V. *To find the area of an irregular polygon.*

Draw diagonals dividing the proposed polygon into trapezia and triangles. Then, having found the areas of all these separately, their sum will be the content required of the whole polygon.

Example. Required the content of the irregular figure ABCDEFGA (fig. 514.), wherein the following diagonals and perpendiculars are given.

AC = 55, GC = 44, Bn = 18, Ep = 8,  
FD = 52, Gm = 13, GO = 12, Dq = 23.

And  $55 \times 9 = 495$   
 $55 \times 6.5 = 357.5$   
 $44 \times 11.5 = 506$   
 $52 \times 6 = 312$   
 $52 \times 4 = 208$

1878.5, area required.

Fig. 514.

1219. PROBLEM VI. *To find the area of a regular polygon.*

Rule 1. Multiply the perimeter of the polygon, or sum of its sides, by the perpendicular drawn from its centre on one of its sides, and take half the product of the area; which is in fact resolving the polygon into so many triangles.

Example. Required the area of the regular pentagon ABCDE (fig. 515.), whose side AB or BC, &c. is 25 ft., and perpendicular OP 17.2 ft.

Here  $\frac{25 \times 5}{2} = 62.5 =$  half the perimeter, and  $62.5 \times 17.2 = 1075$  square feet area required.

Rule 2. Square the side of the polygon, and multiply the square by the tabular area or multiplier set against its name in the following table, and the product will be the area. This rule is founded on the property, that like polygons, being similar figures, are to one another as the squares of their like sides. Now the multipliers of the table are the respective areas of the respective polygons to a side = 1; whence the rule is evident. In the table is added the angle OBP in the several polygons.

Fig. 515.

No. of Sides.	Names.	Multipliers.	Angle OBP.
3	Trigon or equilateral triangle	0.4330127	30°
4	Tetragon or square - -	1.0000000	45°
5	Pentagon - - - -	1.7204774	54°
6	Hexagon - - - -	2.5980762	60°
7	Heptagon - - - -	3.6339124	64½°
8	Octagon - - - -	4.8284271	67½°
9	Nonagon - - - -	6.1818242	70°
10	Decagon - - - -	7.6942088	72°
11	Undecagon - - -	9.3656399	73½°
12	Dodecagon - - -	11.1961524	75°

**Example.** Required the area of an octagon whose side is 20 feet.

Here  $20^2=400$ , and the tabular area 4·8284271 ;

Therefore  $4·8284271 \times 400=1931·37084$  feet, area required.

1220. **PROBLEM VII.** *To find the diameter and circumference of any circle, either from the other.*

**Rule 1.** As 7 is to 22, or as 1 is to 3·1416, so is the diameter to the circumference. Or as 22 is to 7, so is the circumference to the diameter.

**Example.** Required the circumference of a circle whose diameter is 9.

Here  $7 : 22 :: 9 : 28\frac{1}{2}$ ; or,  $\frac{22 \times 9}{7}=28\frac{1}{2}$ , the circumference required.

Required the diameter of a circle whose circumference is 36.

Here  $22 : 7 :: 36 : 11\frac{10}{22}$ ; or,  $\frac{36 \times 7}{22}=11\frac{10}{22}$ , the diameter required.

1221. **PROBLEM VIII.** *To find the length of any arc of a circle.*

**Rule 1.** Multiply the decimal ·01745 by the number of degrees in the given arc, and that by the radius of the circle; then the last product will be the length of the arc.

This rule is founded on the circumference of a circle being 6·2831854 when the diameter is 2, or 3·1415927 when the diameter is 1. The length of the whole circumference then being divided into 360 degrees, we have  $360^\circ : 6·2831854 :: 1^\circ : \cdot 01745$ .

**Example.** Required the length of an arc of 30 degrees, the radius being 9 feet.

Here  $\cdot 01745 \times 30 \times 9=4·7115$ , the length of the arc.

**Rule 2.** From 8 times the chord of half the arc subtract the chord of the whole arc, and one third of the remainder will be the length of the arc nearly.

**Example.** Required the length of an arc DCE (*fig. 516.*) whose chord DE is 48, and versed sine 18.

Here, to find DC, we have  $24^2 + 18^2 = 576 + 324 = 900$ ,  
and  $\sqrt{900} = 30 = DC$ .

Whence  $\frac{30 \times 8 - 48}{3} = \frac{240 - 48}{3} = \frac{192}{3} = 64$ , the length of the arc required.

1222. **PROBLEM IX.** *To find the area of a circle.*

**Rule 1.** Multiply half the circumference by half the diameter. Or multiply the whole circumference by the whole diameter, and take  $\frac{1}{4}$  of the product.

**Rule 2.** Square the diameter, and multiply such square by ·7854.

**Rule 3.** Square the circumference, and multiply that square by the decimal ·07958.

**Example.** Required the area of a circle whose diameter is 10, and its circumference 31·416.

By rule 1.,  $\frac{31·416 \times 10}{4} = 78·54$ .

By rule 2.,  $10^2 \times \cdot 7854 = 100 \times \cdot 7854 = 78·54$ .

By rule 3.,  $31·416 \times 31·416 \times \cdot 07958 = 78·54$ .

So that by the three rules the area is 78·54.

1223. **PROBLEM X.** *To find the area of a circular ring, or of the space included between the circumferences of two circles, the one being contained within the other.*

**Rule.** The difference between the areas of the two circles will be the area of the ring. Or, multiply the sum of the diameters by their difference, and this product again by ·7854, and it will give the area required.

**Example.** The diameters of two concentric circles being 10 and 6, required the area of the ring contained between their circumferences.

Here  $10 + 6 = 16$ , the sum, and  $10 - 6 = 4$ , the difference.

Therefore  $\cdot 7854 \times 16 \times 4 = \cdot 7854 \times 64 = 50·2656$ , the area required.

1224. **PROBLEM XI.** *To find the area of the sector of a circle.*

**Rule 1.** Multiply the radius, or half the diameter, by half the arc of the sector for the area. Or multiply the whole diameter by the whole arc of the sector, and take  $\frac{1}{4}$  of the product. This rule is founded on the same basis as that to Problem IX.

**Rule 2.** As 360 is to the degrees in the arc of the sector, so is the area of the whole circle to the area of the sector. This is manifest, because it is proportional to the length of the arc.

**Example.** Required the area of a circular sector whose arc contains 18 degrees, the diameter being 3 feet.

By the first rule,  $3·1416 \times 3 = 9·4248$ , the circumference.

$360 : 18 :: 9·4248 : \cdot 47124$ , the length of the arc.

$\cdot 47124 \times 3 \div 4 = 1·41372 \div 4 = \cdot 35343$ , the area of the sector.

FIG. 516.

By the second rule,  $7854 \times 32 = 7.0686$ , area of the whole circle.

$360 : 18 :: 7.0686 : .35343$ , the area of the sector.

1225. PROBLEM XII. To find the area of a segment of a circle.

Rule 1. Find the area of the sector having the same arc with the segment by the last problem. Then find the area of the triangle formed by the chord of the segment and the two radii of the sector. Take the sum of these two for the answer when the segment is greater than a semicircle, and their difference when less than a semicircle.

Example. Required the area of the segment ACBDA (fig. 517.), its chord AB being 12, and the radius AE or CE 10.

As  $AE : \sin. \angle D90^\circ :: AD : \sin. 36^\circ : 52\frac{1}{2} = 36.87$  degrees in the arc AC.

Their double  $73.74$  degrees in arc ACB.

Now,  $7854 \times 400 = 314.16$ , the area of the whole circle.

Therefore,  $360^\circ : 73.74 :: 314.16 : 64.3504$ , area of the sector ACBE.

Again,  $\sqrt{AE^2 - AD^2} = \sqrt{100 - 36} = \sqrt{64} = 8 = DE$ .

Therefore,  $AD \times DE = 6 \times 8 = 48$ , the area of the triangle AEB.

Hence the sector ACBE ( $64.350$ ), less triangle AEB ( $48$ ) =  $16.3504$ , area of segment ACBDA.

Fig. 517.

Rule 2. Divide the height of the segment by the diameter, and find the quotient in the column of heights in the following table. Take out the corresponding area in the next column on the right hand, and multiply it by the square of the circle's diameter for the area of the segment. This rule is founded on the principle of similar plane figures being to one another as the squares of their like lineal dimensions. The segments in the table are those of a circle whose diameter is 1. In the first column is contained the versed sines divided by the diameter. Hence the area of the similar segment taken from the table and multiplied by the square of the diameter gives the area of the segment to such diameter. When the quotient is not found exactly in the table, a proportion is used between the next less and greater area.

Example. As before, let the chord AB be 12, and the radius 10 or diameter 20.

Having found as above  $DE = 8$  : then  $CE - DE = CD = 10 - 8 = 2$ . Hence by the rule  $CD \div CF = 2 \div 20 = .1$ , the tabular height; this being found in the first column of the table, the corresponding tabular area is  $.040875$ ; then  $.040875 \times 20^2 = .040875 \times 400 = 16.340$ , the area nearly the same as before.

AREAS OF THE SEGMENTS OF A CIRCLE WHOSE DIAMETER, UNITY, IS SUPPOSED TO BE DIVIDED INTO 1000 EQUAL PARTS.

1226. PROBLEM XIII. *To find the area of an ellipse.*

Rule. Multiply the longest and shortest diameter together, and their product by .7854, which will give the area required. This rule is founded on Theorem 3. Cor. 2. in Conic Sections. (1098, 1100.)

Example. Required the area of an ellipse whose two axes are 70 and 50.

Here  $70 \times 50 \times .7854 = 2748.9$ .

1227. PROBLEM XIV. *To find the area of any elliptic segment.*

Rule. Find the area of a circular segment having the same height and the same vertical axis or diameter; then, as the said vertical axis is to the other axis (parallel to the base of the segment), so is the area of the circular segment first found to the area of the elliptic segment sought. This rule is founded on the theorem alluded to in the previous problem. Or, divide the height of the segment by the vertical axis of the ellipse; and find in the table of circular segments appended to Prob. 12. (1224.) the circular segment which has the above quotient for its versed sine; then multiply together this segment and the two axes of the ellipse for the area.

Example. Required the area of an elliptic segment whose height is 20, the vertical axis being 70, and the parallel axis 50.

Here  $20 \div 70 = .2857142$ , the quotient or versed sine to which in the table answers the segment .285714.

Then  $.285714 \times 70 \times 50 = 648.342$ , the area required.

1228. PROBLEM XV. *To find the area of a parabola or its segment.*

Rule. Multiply the base by the perpendicular height, and take two thirds of the product for the area. This rule is founded on the properties of the curve already described in conic sections, by which it is known that every parabola is  $\frac{2}{3}$  of its circumscribing parallelogram. (See 1097.)

Example. Required the area of a parabola whose height is 2 and its base 12.

Here  $2 \times 12 = 24$ , and  $\frac{2}{3}$  of 24 = 16 is the area required.

## MENSURATION OF SOLIDS.

1229. The measure of every solid body is the capacity or content of that body, considered under the threefold dimensions of length, breadth, and thickness, and the measure of a solid is called its solidity, capacity, or content. Solids are measured by units which are cubes, whose sides are inches, feet, yards, &c. Whence the solidity of a body is said to be of so many cubic inches, feet, yards, &c. as will occupy its capacity or space, or another of equal magnitude.

1230. The smallest solid measure in use with the architect is the cubic inch, from which other cubes are taken by cubing the linear proportions, thus, —

1728 cubic inches = 1 cubic foot;

27 cubic feet = 1 cubic yard.

1231. PROBLEM I. *To find the superficies of a prism.*

Multiply the perimeter of one end of the prism by its height, and the product will be the surface of its sides. To this, if wanted, add the area of the two ends of the prism. Or, compute the areas of the sides and ends separately, and add them together.

Example 1. Required the surface of a cube whose sides are 20 feet.

Here we have six sides; therefore  $20 \times 20 \times 6 = 2400$  feet, the area required.

Example 2. Required the surface of a triangular prism whose length is 20 feet and each side of its end or base 18 inches.

Here we have, for the area of the base,

$1.5^2 - .75^2 = (2.25 - .5625) = 1.6875^2$  for the perpendicular of triangle of base;

and  $\sqrt{1.6875} = 1.299$ , which multiplied by  $1.5 = 1.948$  gives the area of the two bases;

then,  $3 \times 20 \times 1.5 + 1.948 = 91.948$  is the area required.

Example 3. Required the convex surface of a round prism or cylinder whose length is 20 feet and the diameter of whose base is 2 feet.

Here,  $2 \times 3.1416 = 6.2832$ ,

and  $3.1416 \times 20 = 125.664$ , the convex surface required.

1232. PROBLEM II. *To find the surface of a pyramid or cone.*

Rule. Multiply the perimeter of the base by the length of the slant side, and half the product will be the surface of the sides or the sum of the areas of all the sides, or of the areas of the triangles whereof it consists. To this sum add the area of the end or base.

Example 1. Required the surface of the slant sides of a triangular pyramid whose slant height is 20 feet and each side of the base 3 feet.

Here,  $20 \times 3$  (the perimeter)  $\times 3 \div 2 = 90$  feet, the surface required.

**Example 2.** Required the convex surface of a cone or circular pyramid whose slant height is 50 feet and the diameter of its base  $8\frac{1}{2}$  feet.

Here,  $8\frac{1}{2} \times 3.1416 \times 50 \div 2 = 667.5$ , the convex surface required.

**1233. PROBLEM III.** To find the surface of the frustum of a pyramid or cone, being the lower part where the top is cut off by a plane parallel to the base.

**Rule.** Add together the perimeters of the two ends and multiply their sum by the slant height. One half of the product is the surface sought. This is manifest, because the sides of the solid are trapezoids, having the opposite sides parallel.

**Example 1.** Required the surface of the frustum of a square pyramid whose slant height is 10 feet, each side of the base being 3 feet 4 inches and each side of the top 2 feet 2 inches.

Here, 3 feet 4 inches  $\times 4 = 13$  feet 4 inches, and 2 feet 2 inches  $\times 4 = 8$  feet 8 inches; and 13 feet 4 inches  $+ 8$  feet 8 inches  $= 22$ . Then  $22 \div 2 \times 10 = 110$  feet, the surface required.

**Example 2.** Required the convex surface of the frustum of a cone whose slant height is  $12\frac{1}{2}$  feet and the circumference of the two ends 6 and 8.4 feet.

Here,  $6 + 8.4 = 14.4$ ; and  $14.4 \times 12.5 \div 2 = 180 \div 2 = 90$ , the convex surface required.

**1234. PROBLEM IV.** To find the solid content of any prism or cylinder.

**Rule.** Find the area of the base according to its figure, and multiply it by the length of the prism or cylinder for the solid content. This rule is founded on Prop. 99. (Geometry, 980.). Let the rectangular parallelepipedon be the solid to be measured, the small cube P (fig. 518.) being the measuring unit, its side being 1 inch, 1 foot, &c. Let also the length and breadth of the base ABCD, and also let the height AH, be divided into spaces equal to the side of the base of the cube P; for instance, here, in the length 3 and in the breadth 2, making 3 times 2 or 6 squares in the base AC each equal to the base of the cube P. It is manifest that the parallelepipedon will contain the cube P as many times as the base AC contains the base of the cube, repeated as often as the height AH contains the height of the cube. Or, in other words, the contents of a parallelepipedon is found by multiplying the area of the base by the altitude of the solid. And because all prisms and cylinders are equal to parallelepipedons of equal bases and altitudes, the rule is general for all such solids whatever the figure of their base.

**Example 1.** Required the solid content of a cube whose side is 24 inches.

Here,  $24 \times 24 \times 24 = 13824$  cubic inches.

**Example 2.** Required the solidity of a triangular prism whose length is 10 feet and the three sides of its triangular end are 3, 4, and 5 feet.

Here, because (Prop. 32. Geometry, 907.)  $3^2 + 4^2 = 5^2$ , it follows that the angle contained by the sides 3 and 4 is a right angle. Therefore  $\frac{3 \times 4}{2} \times 10 = 60$  cubic feet, the content required.

**Example 3.** Required the content of a cylinder whose length is 20 feet and its diameter 5 feet 6 inches.

Here,  $5.5 \times 5.5 \times .7854 = 23.75835$ , area of base;

and  $23.75835 \times 20 = 47.5167$ , content of cylinder required.

**1235. PROBLEM V.** To find the content of any pyramid or cone.

**Rule.** Find the area of the base and multiply that area by the perpendicular height. One third of the product is the content. This rule is founded on Prop. 110. (Geometry, 991.)

**Example 1.** Required the solidity of the square pyramid, the sides of whose base are 30, and its perpendicular height 25.

Here,  $\frac{30 \times 30}{2} \times 25 = 7500$ , content required.

**Example 2.** Required the content of a triangular pyramid whose perpendicular height is 30 and each side of the base 3.

Here,  $\frac{3+3+3}{2} = \frac{9}{2} = 4.5$ , half sum of the sides;

and  $4.5 - 3 = 1.5$ , one of the three equal remainders. (See Trigonometry, 1052.) but  $\sqrt{4.5 \times 1.5 \times 1.5 \times 1.5 \times 30 \div 3} = 3.897117 \times 10$ , or 38.97117, the solidity required.

**Example 3.** Required the content of a pentagonal pyramid whose height is 12 feet and each side of its base 2 feet.

Here,  $1.7204774$  (tabular area, Prob. 6. 1218.)  $\times 4$  (square of side)  $= 6.8819096$  area of base;

Then  $\frac{6.8819096}{3} = 2.2939698$ , content required.

**Example 4.** Required the content of a cone whose height is  $10\frac{1}{2}$  feet and the circumference of its base 9 feet.

Here,  $\cdot 07958$  (Prob. 9. 1221.)  $\times 81 = 6\cdot 44598$  area of base,

And  $3\cdot 5$  being  $\frac{1}{3}$  of  $10\frac{1}{2}$  feet,  $6\cdot 44598 \times 3\cdot 5 = 22\cdot 56093$  is the content required.

1236. **PROBLEM VI.** *To find the solidity of the frustum of a cone or pyramid.*

Add together the areas of the ends and the mean proportional between them. Then taking one third of that sum for a mean area and multiplying it by the perpendicular height or length of the frustum, we shall have its content. This rule depends upon Prop. 110. (Geometry, 991.).

It may be otherwise expressed when the ends of the frustum are circles or regular polygons. In respect of the last, square one side of each polygon, and also multiply one side by the other; add the three products together, and multiply their sum by the tabular area for the polygon. Take one third of the product for the mean area, which multiply by the length, and we have the product required. When the case of the frustum of a cone is to be treated, the ends being circles, square the diameter or the circumference at each end, and multiply the same two dimensions together. Take the sum of the three products, and multiply it by the proper tabular number, that is, by  $\cdot 7854$ , when the diameters are used, and  $\cdot 07958$  when the circumferences are used, and, taking one third of the product, multiply it by the length for the content required.

**Example 1.** Required the content of the frustum of a pyramid the sides of whose greater ends are 15 inches, and those of the lesser ends 6 inches, and its altitude 24 feet.

Here,  $5 \times 5 = 25$ , area of the lesser end,

and  $1\cdot 25 \times 1\cdot 25 = 1\cdot 5625$ , area of the greater end:

The mean proportional therefore  $\sqrt{25 \times 1\cdot 5625} = 6\cdot 25$ .

Again,  $\frac{25 + 6\cdot 25 + 1\cdot 5625}{3} = \frac{2\cdot 4375}{3} = 8\cdot 125$ , mean area,

and  $8\cdot 125 \times 24$  (altitude)  $= 19\cdot 5$  feet, content required.

**Example 2.** Required the content of a conic frustum whose altitude is 18 feet, its greatest diameter 8, and its least diameter 4.

Here,  $64$  (area gr. diam.)  $+ 16$  (less. diam.)  $+ (8 \times 4) = 112$ , sum of the products;

and  $\frac{7854 \times 112 \times 18}{3} = 527\cdot 7888$ , content required.

**Example 3.** Required the content of a pentagonal frustum whose height is 5 feet, each side of the base 18 inches, and each side of the upper end 6 inches.

Here,  $1\cdot 5^2 + 1\cdot 5^2 + (1\cdot 5 \times 5) = 2\cdot 5625$ , sum of the products;

but,  $\frac{1\cdot 7204774 \text{ (tab. area)} \times 2\cdot 5625 \text{ (sum of products)} \times 5}{3} = 9\cdot 31925$ , content required.

1237. **PROBLEM VII.** *To find the surface of a sphere or any segment.*

**Rule 1.** Multiply the circumference of the sphere by its diameter, and the product will be the surface thereof. This and the rules in the following problems depend on Props. 113. and 114. (Geometry, 994, 995.), to which the reader is referred.

**Rule 2.** Square the diameter, and multiply that square by  $3\cdot 1416$  for the surface.

**Rule 3.** Square the circumference, then either multiply that square by the decimal  $\cdot 3183$ , or divide it by  $3\cdot 1416$  for the surface.

**Remark.** For the surface of a segment or frustum, multiply the whole circumference of the sphere by the height of the part required.

**Example 1.** Required the convex superficies of a sphere whose diameter is 7 and circumference 22.

Here,  $22 \times 7 = 154$ , the superficies required.

**Example 2.** Required the superficies of a sphere whose diameter is 24 inches.

Here,  $24 \times 24 \times 3\cdot 1416 = 1809\cdot 5616$  is the superficies required.

**Example 3.** Required the convex superficies of a segment of a sphere whose axis is 42 inches and the height of the segment 9 inches.

Here,  $1 : 3\cdot 1416 :: 42 : 131\cdot 9472$ , the circumference of the sphere;

but  $131\cdot 9472 \times 9 = 1187\cdot 5248$ , the superficies required.

**Example 4.** Required the convex surface of a spherical zone whose breadth or height is 2 feet and which forms part of a sphere whose diameter is  $12\frac{1}{2}$  feet.

Here,  $1 : 3\cdot 1416 :: 12\cdot 5 : 39\cdot 27$ , the circumference of the sphere whereof the zone is a part;

and  $39\cdot 27 \times 2 = 78\cdot 54$ , the area required.

1238. **PROBLEM VIII.** *To find the solidity of a sphere or globe.*

**Rule 1.** Multiply the surface by the diameter, and take one sixth of the product for the content.

**Rule 2.** Take the cube of the diameter and multiply it by the decimal  $\cdot 5236$  for the content.

**Example.** Required the content of a sphere whose axis is 12.

Here  $12 \times 12 \times 12 \times \cdot 5236 = 904\cdot 7808$ , content required.

1239. PROBLEM IX. *To find the solidity of a spherical segment.*

Rule 1. From thrice the diameter of the sphere subtract double the height of the segment, and multiply the remainder by the square of the height. This product multiplied by  $\cdot 5236$  will give the content.

Rule 2. To thrice the square of the radius add the square of its height, multiply the sum thus found by the height, and the product thereof by  $\cdot 5236$  for the content.

Example 1. Required the solidity of a segment of a sphere whose height is 9, the diameter of its base being 20.

Here, 3 times the square of the radius of the base = 300 ;

and the square of its height = 81, and  $300 + 81 = 381$  ;

but  $381 \times 9 = 3429$ , which multiplied by  $\cdot 5236 = 1795\cdot 4244$ , the solidity required.

Example 2. Required the solidity of a spherical segment whose height is 2 feet and the diameter of the sphere 8 feet.

Here,  $8 \times 3 - 4 = 20$ , which multiplied by  $4 = 80$  ;

and  $80 \times \cdot 5236 = 41\cdot 888$ , the solidity required.

It is manifest that the difference between two segments in which the zone of a sphere is included will give the solidity of the zone. That is, where for instance the zone is included in a segment lying above the diameter, first consider the whole as the segment of a sphere terminated by the vertex and find its solidity ; from which subtract the upper part or segment between the upper surface of the zone and the vertex of the sphere, and the difference is the solidity of the zone.

The general rule to find the solidity of a frustum or zone of a sphere is : to the sum of the squares of the radii of the two ends add one third of the square of their distance, or the breadth of the zone, and this sum multiplied by the said breadth, and that product again by  $1\cdot 5708$ , is the solidity.

## SECT. VIII.

### MECHANICS AND STATICS.

1240. It is our intention in this section to address ourselves to the consideration of mechanics and statics as applicable more immediately to architecture. The former is the science of forces, and the effects they produce when applied to machines in the motion of bodies. The latter is the science of weight, especially when considered in a state of equilibrium.

1241. The centre of motion is a fixed point about which a body moves, the axis being the fixed line about which it moves.

1242. The centre of gravity is a certain point, upon which a body being freely suspended, such body will rest in any position.

1243. So that weight and power, when opposed to each other, signify the body to be moved, and the body that moves it, or the patient and agent. The power is the agent which moves or endeavours to move the patient or weight, whilst by the word equilibrium is meant an equality of action or force between two or more powers or weights acting against each other, and which by destroying each other's effects cause it to remain at rest.

### PARALLELOGRAM OF FORCES.

1244. If a body D suspended by a thread is drawn out of its vertical direction by an horizontal thread DE (fig. 519.), such power neither increases nor diminishes the effort

Fig. 519.

Fig. 520.

Fig. 521.

of the weight of the body ; but it may be easily imagined that the first thread, by being in the direction AD, will, besides the weight itself, have to sustain the effort of the power that draws it out of the vertical AB.

1245. If the direction of the horizontal force be prolonged till it meets the vertical, which would be in the first thread if it were not drawn away by the second, we shall have triangle ADB, whose sides will express the proportion of the weight to the forces of the two threads in the case of equilibrium being established; that is, supposing AB to express the weight, AD will express the effort of the thread attached to the point A, and BD that of the horizontal power which pulls the body away from the vertical AB.

1246. These different forces may also be found by transferring to the vertical DH (fig. 520.) any length of line DF to represent the weight of the body. If from the point F the parallels FI, FG be drawn in the direction of the threads, their forces will be indicated by the lines ID, DG, so that the three sides of the triangle DGF, similar to the triangle ADB, will express the proportion of the weight to the two forces applied to the threads.

1247. Suppose the weight to be 30 lbs.: if from a scale of equal parts we set up 30 of those parts from D to F (*fig.* 519.), we shall find DG equal to 21, or the pounds of force of the horizontal line DE, and 35 for the oblique power ID.

1248. If the weight, instead of 30 lbs., were 100, we should find the value of the forces DG and ID by the proportions of 30 : 21 :: 100 :  $x$ , where  $x$  expresses the force DG. The value resulting from this proportion is  $x = \frac{21 \times 100}{30} = 70$ . The second proportion

$30 : 35 :: 100 : y$ , where  $y$  represents the effort ID, whose value will be  $y = \frac{35 \times 100}{30} = 116.666$ .

1249. If the angle ADH formed by AD and DH be known, the same results may be obtained by taking DF for the radius, in which case IF = DG becomes the tangent, in this instance, of 35 degrees, and ID the secant: whence

$$DF : DI : IF :: \text{radius} : \text{tang. } 35 : \text{sec. } 35.$$

If ID be taken for the radius, we have

$$ID : IF : FD :: \text{radius} : \text{tang. } 35 : \text{sin. } 35.$$

1250. We have here to observe, that in conducting the operation above mentioned a figure DIFG has been formed, which is called the parallelogram of the forces, because the diagonal DF always expresses a compounded force, which will place in equilibrio the two others FI, FG, represented by the two contiguous sides IF, FG.

1251. Instead of two forces which draw, we may suppose two others which act by pushing from E to D (*fig. 522.*) and from A to D. If we take the vertical DF to express the weight, and we draw as before the parallels FG and FI in the direction of the forces, the sides GD and DI of the parallelogram DGFI (*fig. 519.*) will express the forces with which the powers act relatively to DF to support the body: thus FI = GD the weight and two powers which support it will, in case of equilibrium, be represented by the three sides of a rectangular triangle DFI; so that if the weight be designated by H, the power which pushes from G to D by E, and that which acts from I to D by P, we shall have the proportion  $H : E : P :: DF : FI : ID$ , wherein, if we take DF for radius, it will be as radius is to the tangent of the angle FDI and to its secant.

Fig. 522.

**Fig. 522.**

As a body in suspension is drawn away from the vertical line in which it hangs by a power higher than the body (*fig. 520.*), it follows that the oblique forces AB and BC each support, independent of any lateral efforts, a part of the weight of the body. In order to find the proportion of these parts to the total weight, take any distance BD on a vertical raised from the centre of the body B to express the weight, and complete the parallelogram DEBF, whose sides EB, BF will express the oblique forces of the powers A and C. These lines, being considered as the diagonals of the rectangular parallelograms LEIB, BHFM, may each be resolved into two forces, whereof one of them, vertical, sustains the body, and the other, horizontal, draws it away from the verticals AO, CQ. Hence IB will express the vertical force, or that part of the weight sustained by the power EB, and HB that sustained by the other power BF: as these two forces act in the same direction, when added together their sum will represent the weight DB. In short, IB being equal to HD, it follows that  $BH + BI = BI + ID$ .

1252. As to the horizontal forces indicated by the lines LB and BM, as they are equal and opposite they destroy one another.

1253. It follows, from what has been said, that all oblique forces may be resolved into two others, one of which shall be vertical and the other horizontal, by taking their direction for the diagonal of a rectangular parallelogram.

1254. In respect of their ratio and value, those may be easily found by means of a scale if the diagram be drawn with accuracy; or by trigonometry, if we know the angles

ABD, DBC, which AB and BC form with the vertical BD, by taking successively for radius the diagonals BD, BE, and BF.

1255. In the accompanying diagram, the weight, instead of being suspended by strings acting by tension, is sustained by forces which are supposed to act by pushing. But as this arrangement makes no alteration in the system of forces, we may apply to this figure all that has been said with respect to the preceding one. The only difference is, that the parallelogram of the forces is below the weight instead of being above it. Thus  $ID + IB = BD$  expresses the sum of the vertical forces which support the weight, and MB and BL the horizontal forces which counteract each other.

Fig. 523.

1256. In the two preceding figures the direction of the forces which act by tension or compression in supporting the weight form an acute angle. In those represented in *fig. 521.* and the figure at the side (*524.*), these directions make an obtuse angle; whence it follows that in *fig. 521.* the force C which draws the weight out of the vertical AL, instead of tending to support the weight B, increases its effect by its tendency to act in the same direction. In order to ascertain the amount of this effect upon BD in *figs. 521.* and *524.*, which represents the vertical action of the weight, describe the parallelogram BADF, for the purpose of determining the oblique forces BA, BF, and then take these sides for the diagonals of the two rectangles LAIB, BIIFM, whose sides BI, BH will express the vertical forces, and LB, BM the horizontal ones.

weight out of the vertical

Fig. 524.

1257. It must be observed that in *fig. 521.* the force AB acting upwards renders its vertical effect greater than the weight of a quantity ID, which serves as a compensation to the part BH, that the other force BF adds to the weight by drawing downwards. Similarly, the vertical effect of the force BE (*fig. 524.*) exceeds the expression BD of the weight by a quantity DI, to counterpoise the effect BH of the other power BF, which acts downwards; so that in both cases we have BD only for the vertical effect of the weight. As to the horizontal effects LB and BM, they being equal and in opposite directions in both figures, they counteract each other.

1258. For the same reason that a force can be resolved into two others, those two others may be resolved into one, by making that one the diagonal of a parallelogram whose forces are represented by two contiguous sides. It is clear, then, that whatever the number of forces which affect any point, they may be reduced into a single one. It is only necessary to discover the results of the forces two by two, and to combine these results similarly two by two, till we come to the principal ones, which may be ultimately reduced to one, as we have seen above. By such a process we shall find that PY (*fig. 525.*) is the result of the forces PA, PB, PC, PD, which affect the point P.

Fig. 525.

1259. This method of resolving forces is often of great utility in the science of building, for the purpose of providing a force to resist several others acting in different directions but meeting in one point.

#### OF THE PROPERTIES OF THE LEVER.

1260. The *lever* is an inflexible rod, bar, or beam serving to raise weights, whilst it is supported at a point by a *fulcrum*, or prop, which is the centre of motion. To render the demonstrations relative to it easier and simpler, it is supposed to be void of gravity or weight. The different positions in which the power applied to it, and the weight to be affected, may be applied in respect of the fulcrum, have given rise to the distinction of three sorts of levers.

I. That represented in *fig. 526.*, in which the fulcrum O is between the power applied P and the weight Q.

II. That represented in *fig. 527.*, in which the weight Q is placed between the fulcrum

O and the power P, wherein it is to be remarked that the weight and the power act in contrary directions.

Fig. 526.

Fig. 527.

Fig. 528.

III. That represented in *fig. 528.*, wherein the power P is placed between the weight and the fulcrum, in which case the power and the weight act in contrary directions.

1261. In considering the fulcrum of these three sorts of levers as a third species of power introduced for creating an equilibrium between the others, we must notice, 1st, That in which the directions of the weight and of the powers concur in the point R (*fig. 529.*). 2d, That in which they are parallel.

1262. In the first case, if from the point R (*figs. 529. and 530.*) we draw parallel to these directions Om Rn, the ratio of these three forces, that is, the power, the weight, and the fulcrum, will be as the three sides of the triangle OmR, or its equal OnR; thus we shall have  $P : Q : R :: mR : Rn : OR$ ; and as the sides of a triangle are as the sines of their opposite angles, by taking OR as the radius we shall have

$$P : Q :: \sin. ORn : \sin. ORm.$$

And if from the point O two perpendiculars be let fall, OdOf, on the directions RQ, RP,

$$\sin. ORn : \sin. ORm :: Od : Of;$$

from which two proportions we obtain

$$P : Q :: Od : Of; \text{ whence } P \times Of = Q \times Od.$$

This last expression gives equal products, which are called the *momenta*, *moments*, or quantities of motion of the force in respect of the fulcrum O. This property is the same for the straight as for the angular levers (*figs. 529. and 530.*). As this proportion exists, however large the angles mRO and ORn of the directions RQ, RP in respect to RO, it follows that when it becomes nothing, these directions become parallel without the proportion being changed; whence is derived the following general theorem, found in all works on mechanics: — *If two forces applied to a straight or angular lever are in equilibrium, they are in an inverse ratio to the perpendiculars let fall from the fulcrum on their lines of direction: or in other words, In order that two forces applied to a straight or angular lever may be in equilibrium, their momenta in respect of the fulcrum must be equal.*

1263. Since, in order to place the lever in equilibrio, it is sufficient to obtain equal momenta, it follows that if we could go on increasing or diminishing the force, we might place it at any distance we please from the fulcrum, or load it without destroying the equilibrium. This results from the formula  $P \times Of = Q \times Od$ ,

whence we have  $Of = \frac{Q \times Od}{P}$ . Hence the distance Of is easily found, to which by applying the known force P, it may counterpoise the weight Q applied at the distance Od. In respect of the other points, we have only to know the perpendiculars Of and Od, for Oa and Ob, which are the arms of the real levers, are deduced from the triangles Ofb, Oda, to which they belong.

1264. Suppose two levers (*figs. 531, 532.*), whereof

Fig. 531.

Fig. 532.

one is straight and the other angular, and that the weight  $Q$  is 100 pounds, the arm  $DE$  of the lever 6 feet; its momentum will be 600. Then if we wish to ascertain at what distance  $Of$  a weight of 60 pounds must be placed so that it may be in equilibrio with the first, we shall have

$$Of = \frac{Q \times Od}{P} = \frac{600}{60} = 10 \text{ feet, the distance sought.}$$

1265. Reciprocally, to find the effect of a force  $P$  placed at the point  $C$  of the other arm of the lever at a known distance from the fulcrum, and marked  $Of$ , in order to counterpoise  $Q$  placed at the distance  $Od$ , we have the formula  $P = \frac{Q \times Od}{Of}$ ; and if we apply this formula to the numbers taken in the preceding example, the question will be, to find a force which placed at the distance of 10 feet from the fulcrum may be in equilibrio with a weight of 100 pounds at the end of the arm of a lever of 6 feet. We must in using the formula divide 600 by 10, and the quotient 60 will indicate the effect with which the force ought to act. If, instead of placing it in  $C$ , it is at  $B$ , 12 feet from the fulcrum, the force would be  $\frac{600}{12}$ , which gives 50; and lastly, if we have to place it at a point 15 feet from the fulcrum, the force would be  $\frac{600}{15} = 40$ . Thus, in changing the situation of the force to a point more or less distant from the fulcrum, we must divide the momentum of the weight which is to be supported by the distance from the fulcrum taken perpendicularly to its direction.

#### OF THE CENTRE OF GRAVITY.

1266. The centre of gravity of a body is a certain point within it on which the body, if freely suspended, will rest in any position; whilst in other positions it will descend to the lowest place to which it can get. Not only do whole bodies tend by their weight to assume a vertical direction, but also all the parts whereof they consist; so that if we suspend any body, whatever be its form, by means of a string, it will assume such a position that the thread produced to the internal part of the body will form an axis round which all the parts will remain in equilibrium. Every time that the point of suspension of a body is changed, the direction of the thread produced exhibits a new axis of equilibrium. But it is to be remarked, that all these axes intersect each other in the same point situate in the centre of the mass of the body, supposing it composed of homogeneous parts but sometimes out of the mass of the body, as in the case of bodies much curved, this point is the centre of gravity.

1267. It is therefore easy to perceive that for a body to be in a state of rest its centre of gravity must be supported by a vertical force equal to the resultant of all the forces that affect it, but acting in a contrary direction. So in *figs.* 520. and 523., the weight supported by the forces  $AB$  and  $BC$  which draw or push, will be equally supported by a vertical force represented by the diagonal  $DB$  of the parallelogram which expresses the resultant of the forces.

1268. An acquaintance with the method of finding centres of gravity is indispensable in estimating the resistances, strains, and degree of stability of any part of an edifice. There arise cases in which we may cast aside all consideration of the form of a body, especially too when it acts by weight, and suppose the whole figure collected in the centre of gravity. We may also, for the sake of simplifying operations, substitute a force for a weight.

#### OF THE CENTRE OF GRAVITY OF LINES.

1269. A straight line may be conceived to be composed of an infinite number of points, equally heavy, ranged in the same direction. After this definition, it is evident that if it be suspended by the middle, the two parts, being composed of the same number of equal points placed at equal distances from the point of suspension, will be necessarily in equilibrium; whence it follows that the centre of gravity of a right line is in the middle of its length.

1270. The points in a curve line not being in the same direction, the centre of its volume cannot be the same as its centre of gravity; that is to say, that a curve suspended by the middle cannot be supported in equilibrio but in two opposite situations; one when the branches of the curve are downwards, and the other when they are upwards, so that the curve may be in a vertical plane.

1271. If the curve is the arc of a circle  $ADB$  (*fig.* 533.), it is easy to see that from the uniformity of its curvature, its centre of gravity will be found in the right line  $DC$  drawn from the centre  $C$  to the middle  $D$ ; moreover, if we draw the chord  $AB$ , the centre of gravity will be found between the points  $D$  and  $E$ .

Fig. 533.

1272. Let us suppose that through all the points of the line  $DE$  parallels to the chord  $AB$  be drawn, terminated on each side by the curve: and let us imagine that each of these

lines at its extremities bears corresponding points of the curve; then the line DE will be loaded with all these weights; and as the portions of the curve which answer to each parallel AB go on increasing as they approach D, the centre of gravity G will be nearer the point D than to the point E.

1273. To determine the position of this point upon the radius CD which divides the arc into two equal parts, we must use the following proportion: the length of the arc ABD is to the chord AB, as the radius CD is to the fourth term  $x$ , whose value is  $\frac{AB \times CD}{ABD}$ . That is, in order to obtain upon the radius DC the distance CG of the centre of gravity from the centre of the arc of the circle, the chord AB must be multiplied by the radius CD and divided by the length of the arc ABD.

1274. When the circumference of the circle is entire, the axes of equilibrium being diameters, it is manifest that their intersection gives the centre of the curve as the centre of gravity. It is the same with all entire and symmetrical curves which have a centre, and with all combinations of right lines which form regular and symmetrical polygons.

#### OF THE CENTRE OF GRAVITY OF SURFACES.

1275. In order that a centre of gravity may be assigned to a surface, we must, as in the case of lines, imagine them to be material, that is, consisting of solid, homogeneous, and heavy particles.

1276. In all plane smooth surfaces, the centre of gravity is the same as that of the volume of space; thus the centre of gravity G (figs. 534, 535, 536.), of a square of a rectangle, or of a parallelogram, is determined by the intersections of its diagonals AD, BC.

The centre of gravity of a regular polygon, composed of an equal or unequal number of sides, is the same as that of a circle within which it may be inscribed.

1277. In order to find the centre of gravity of any triangle, bisect each of the sides, and from the points of bisection draw lines to the opposite angles; the point of intersection with each other of these lines will be the centre of gravity sought; for in the supposition that the surface of the triangle is composed of lines parallel to its sides, the lines AE, BF, and CD (fig. 537.) will be the axes of equilibrium, whose intersection at G gives the centre of gravity. We shall moreover find that this point is at one third of the distance from the base of each of the axes; so that, in fact, it is only necessary to draw a line from the point of bisection of one of the sides to the opposite angle, and to divide it into three equal parts, whereof that nearest the base determines the centre of gravity of the triangle.

1278. To find the centre of gravity of any irregular rectilinear surface, such as the pentagon, fig. 538., let it be divided into the three triangles, AED, ABC, ADC (fig. 538.), and by the preceding rule determine their centres of gravity F, G, H. Then draw the two lines NO, OP, which form a right angle surrounding the polygon. Multiply the area of each triangle by the distance of its centre of gravity on the line ON, indicated by Ff, Gg, Hh, and divide the sum of these products by the entire area of the pentagon, and this will give a mean distance through which an indefinite line IK parallel to ON is to be drawn. Conducting a similar operation in respect of the line OP, we obtain a new mean distance for drawing another line LQ parallel to OP, which will intersect the first in the point M, the centre of gravity of the pentagon.

The centre of gravity of a sector of a circle AEBC (fig. 539.) must be upon the radius CE which divides the arc into two equal parts. To determine from the centre C, at

Fig. 534.

Fig. 535.

Fig. 536.

Fig. 537.

Fig. 538.

what distance the point  $G$  is to be placed, we must multiply twice the radius  $CE$  by the chord  $AB$ , and divide the product by thrice the length of the arc  $AEB$ . The quotient is the distance  $CG$  from the centre  $C$  of the circle of the centre of gravity of the sector.

1279. To find the centre of gravity of the crown portion of an arch  $DAEBF$  (*fig. 540.*) comprised between two concentric axes, we must —

1. Find the centre of gravity of the greater sector  $AECB$ , and that of the smaller one  $DFC$ .

2. Multiply the area of each of these sectors by the distance of their respective centres of gravity from the common centre  $C$ .

3. Subtract the smaller product from the greater, and divide the remainder by the area of  $DAEBF$ ; the quotient will give the distance of the centre of gravity  $G$  from the centre  $C$ .

1280. To determine the centre of gravity of the segment  $AEB$ ; subtract the product of the area of the triangle  $ABC$  (*fig. 541.*) multiplied by the distance of its centre of gravity from the centre  $C$ , from the product of the area of the sector, by the distance of its centre of gravity from the same point  $C$ , and divide the remainder by the area  $AEB$ ; the quotient expresses the distance of the centre of gravity  $G$  of the segment from the centre  $C$ , which is to be set out on the radius, and which divides the segment into two equal parts.

It would, from want of space, be inconvenient to give the strict demonstrations of the above rules; nor, indeed, is it absolutely necessary for the architectural student. Those who wish to pursue the subject *au fond*, will, of course, consult more abstruse works on the matter. We will merely observe, that whatever the figure whose centre of gravity is sought, it is only necessary to divide it into triangles, sectors, or segments, and proceed as above described for the pentagon, *fig. 538.*

#### OF THE CENTRE OF GRAVITY OF SOLIDS.

1281. It is supposed in the following considerations, that solids are composed of homogeneous particles whose weight in every part is uniform. They are here arranged under two heads, regular and irregular.

1282. Regular solids are considered as composed of elements of the same figure as their base, placed one upon the other, so that all their centres of gravity are in a vertical line, which we shall call the right axis. Thus parallelopipeds, prisms, cylinders, pyramids, cones, conoids, spheres, and spheroids have a right axis, whereon their centre of gravity is found.

1283. In parallelopipeds, prisms, cylinders, spheres, spheroids, the centre of gravity is in the middle of the right axis, because of the similarity and symmetry of their parts equally distant from that point.

1284. In pyramids and cones (*figs. 542, 543.*), which diminish gradually from the base to the apex, the centre of gravity is at the distance of one fourth of the axis from the base.

1285. In paraboloids, which diminish less on account of their curvature, the centre of gravity is at the height of one third the axis above the base.

To find the centre of a pyramid or of a truncated cone (*figs. 542, 543.*), we must first multiply the cube of the entire cone or pyramid by the distance of its centre of gravity from the vertex. 2. Subtract from this product that of the part  $MSR$  which is cut off, by the distance of its centre of gravity from the apex. 3. Divide this remainder by the cube of the truncated pyramid or cone; the quotient will be the distance of the centre of gravity  $G$  of the part of the truncated cone or pyramid from its apex.

Fig. 539.

Fig. 540.

Fig. 541.

Fig. 542.

Fig. 543.

1286. The centre of gravity of a hemisphere is at the distance of three eighths of the radius from the centre.

1287. The centre of gravity of the segment of a sphere (*fig. 544.*) is found by the following proportion: as thrice the radius less the thickness of the segments is to the diameter less three quarters the thickness of the segment, so is that thickness to a fourth term which expresses the distance from the vertex to the centre of gravity, set off on the radius which serves as the axis.

1288. Thus, making  $r$  = the radius,  $e$  = the thickness of the segment, and  $x$  = the distance sought, we have, according to La Caille,—

$$3r - e : 2r - \frac{3e}{4} :: e : x, \text{ whence } x = \frac{8re - 3e^2}{12r - 4e}.$$

Suppose the radius to be 7 feet, the thickness of the segment 3 feet, we shall have —

$$x = \frac{8 \times 7 \times 3 - 3 \times 9}{12 \times 7 - 3 \times 4}, \text{ which gives } x = 1 + \frac{99}{8} = 1 + \frac{24}{3}, \text{ equal the distance of the centre of gravity from its vertex on the radius.}$$

1289. To find the centre of gravity of the zone of a sphere (*fig. 545.*), the same sort of operation is gone through as for truncated cones and pyramids; that is, after having found the centre of gravity of the segment cut off, and that in which the zone is comprised, multiply the cube of each by the distance of its centre of gravity from the apex A, and subtracting the smaller from the larger product, divide the remainder by the cube of the zone. Thus, supposing, as before, the radius AC = 7, the thickness of the zone = 2, and that of the segment cut off = 1, we shall find the distance from the vertex of the centre of gravity of this last by the formula  $x = \frac{8rc - 3ce}{4(3r - e)}$ , which in this case gives  $x = \frac{4 \times 2 \times 7 \times 1 - 3 \times 2 \times 1}{4(21 - 1)}$ ; and pursuing the investigation, we have  $x = \frac{103}{103}$ , which will be the distance of the centre of gravity from the vertex A. That of the centre of gravity of the segment in which the zone is comprised will, according to the same formula, be  $x = \frac{8 \times 7 \times 2 - 3 \times 2 \times 2}{4 \times 3 \times 7 - 3}$ , which gives  $x = 2 + \frac{11}{10}$  for the distance of the centre of gravity from the same point A.

1290. The methods of finding the solidities of the bodies involved in the above investigation are to be found in the preceding section, on Mensuration.

#### OF THE CENTRE OF GRAVITY OF IRREGULAR SOLIDS.

1291. As all species of solids, whatever their form, are susceptible of division into pyramids, as we have seen in the preceding observations, it follows that their centres of gravity may be found by following out the instructions already given. Instead of two lines at right angles to each other, let us suppose two vertical planes NAC, CEF (*fig. 546.*), between which the solid G is placed. Carrying to each of those planes the momenta of their pyramids, that is, the products of their solidity, and the distances of their centres of gravity, divide the sum of these products for each plane by the whole solidity of the body, the quotient will express the distance of two other planes BKL, DHM, parallel to those first named. Their intersection will give a line IP, or an axis of equilibrium, upon which the centre of gravity of the solid will be found. To determine the point G, imagine a third plane NOF perpendicular to the preceding ones, that is, horizontal; upon which let the solid be supposed to stand. In respect of this plane let the momenta of the pyramids be found by also multiplying their solidity by the distance of their centres of gravity. Lastly, dividing the sum of these products by the solidity of the entire body, the quotient gives on the axis the distance PG of this third plane from the centre of gravity of the irregular solid.

Mechanically, where two of the surfaces of a body are parallel, the mode of finding the centre of gravity is simple. Thus, if the body be hung up by any point A (*figs. 547, 548.*), and a plumb line AB be suspended from the same point, it will pass through

Fig. 544.

Fig. 545.

Fig. 546.

Fig. 547.

Fig. 548.

the centre of gravity, because that centre is not in the lowest point till it fall in the plumb line. Mark the line AB upon it; then hang the body up by any other point D, with a plumb line DE, which will also pass through the centre of gravity, for the same reason as before. Therefore the centre of gravity will be at C, where the lines cross each other.

1292. We have, perhaps, pursued this subject a little further than its practical utility in architecture renders necessary; but cases may occur in which the student will find our extended observations of service.

## OF THE INCLINED PLANE.

1293. That a solid may remain in a perfect state of rest, the plane on which it stands must be perpendicular to the direction of its gravity; that is, level or horizontal, and the vertical let fall from its centre of gravity must not fall out of its base.

1294. When the plane is not horizontal, solids placed on it tend to slide down or to overturn.

1295. As the surfaces of bodies are more or less rough, when the direction of the centre of gravity does not fall without their base, they slide down a plane in proportion to their roughness and the plane's inclination.

1296. Thus a cube of hard freestone, whose surfaces are nicely wrought, does not slide down a plane whose inclination is less than thirty degrees; and with polished marbles the inclination is not more than fifteen degrees.

1297. When a solid is placed on an inclined plane, if the direction of the centre of gravity falls without its base, it overturns if its surfaces are right surfaces, and if its surface is convex it rolls down the plane.

1298. A body with plane surfaces may remain at rest after having once overturned if the surface upon which it falls is sufficiently extended to prevent its centre of gravity falling within the base, and the inclination be not so great as to allow of its sliding on.

1299. Solids whose surfaces are curved can only stand upon a perfectly horizontal plane, because one of the species, as the sphere, rests only on a point, and the other, as cylinders and cones, upon a line; so that for their continuing at rest, it is necessary that the vertical let fall from their centre of gravity should pass through the point of contact with and be perpendicular to the plane. Hence, the moment the plane ceases to be horizontal the direction of the centre of gravity falls out of the point or line of contact which serves as the base of the solid, and the body will begin to roll; and when the plane on which they thus roll is of any extent they roll with an accelerated velocity, equal to that which they would acquire in falling directly from the vertical height of the inclined plane from the point whence they first began to roll.

1300. To find the force which is necessary to support a convex body upon an inclined plane, we must consider the point of contact F (*figs. 549, 550.*) as the fulcrum of an an-

Fig. 549.

Fig. 550.

gular lever, whose arms are expressed by the perpendiculars drawn from the fulcrum to the direction of the force CP and the weight CD, which in the case of *fig. 549.*, where the force which draws the body is parallel to the plane,

$$P : N :: FC : FD.$$

Now as the rectangular triangle CFD is always similar to the triangle OSH, which forms the plane inclined by the vertical SO and the horizontal line OH, the proportion will stand as follows:—

$$P : N :: OS : SH.$$

In the first case, to obtain an equilibrium, the force must be to the weight of the body as the height OS of the inclined plane to its length SH.

1301. In the case where the force is horizontal (*fig. 550.*) we have, similarly,—

$$P : N :: FA : FD,$$

$$\text{and } P : N :: OS : OH.$$

In this last case, then, the force must be to the weight of the solid in proportion to the height

**OS of the inclined plane to its base OH.** In the first case the pressure of the solid on the plane is expressed by OH, and in the second by SH: hence we have—

$$P : N : F :: OS : SH : OH,$$

$$\text{and } P : N : F :: OS : SH : OH.$$

In the first case it must be observed, that the effect of the force being parallel to the inclined plane, it neither increases nor diminishes the pressure upon that plane; and this is the most favourable case for keeping a body in equilibrio on an inclined plane. In the second case, the direction forming an acute angle with the plane uselessly augments the load or weight. Whilst the direction of the force forms an obtuse angle with the inclination of the plane, by sustaining a portion of the weight, it diminishes the load on the plane, but requires a greater force.

1302. The force necessary to sustain upon an inclined plane a body whose base is formed by a plane surface depends, as we have already observed, on the roughness of the surfaces, as well of the inclined plane as of the base of the body; and it is only to be discovered by experiments.

1303. Of all the means that have been employed to estimate the value of the resistance, known under the name of friction, the simplest, and that which seems to give the truest results, is to consider the inclination of the plane upon which a body, the direction of whose centre of gravity does not fall out of the base, remains in equilibrio, as a horizontal plane; after which the degrees of inclination may begin to be reckoned, by which we find that a body which does not begin to slide till the plane's inclination exceeds 30 degrees, being placed on an inclined plane of 45, will not require a greater force to sustain it than a convex body of the same weight on an inclined plane of 15 degrees.

1304. All that has been said on the force necessary to retain a body upon an inclined plane, is applicable to solids supported by two planes, considering that the second acts as a force to counterpoise the first, in a direction perpendicular to the second plane.

1305. When the directions of three forces, PG, QG, GR, meet in the same point G (*fig. 551.*), it follows, from the preceding observations on the parallelogram of forces, that to be in equilibrio their proportion will be expressed by the three sides of a triangle formed by perpendiculars to their directions; whence it follows, that if through the centre of gravity G of a solid, supported by two planes or by some other point of its vertical direction, lines be drawn perpendicular to the directions of the forces, if equilibrio exist, so will the following proportion, viz.  $P : Q : R :: BA : BC : AC$ .

Fig. 551.

1306. Lastly, considering that in all sorts of triangles the sides will between each other be as the sines of their opposite angles, we shall have  $P : Q : R :: \sin. BCA : \sin. BAC : \sin. ABC$ ; and as the angle BCA is equal to the angle CAD, and CBA to BAE, we shall have  $P : Q : R :: \sin. CAD : \sin. BAC : \sin. BAE$ ; that is, that the weight is represented by the sine of the angle formed by the two inclined planes, and that the pressures upon each of these planes are reciprocally proportional to the sines of the angles which they form with the horizon.

#### THE WHEEL AND AXLE.

1307. The wheel and axle, sometimes called the axis in peritrochio, is a machine consisting of a cylinder C and a wheel B (*fig. 552.*) having the same axis, at the two extremities of which are pivots on which the wheel turns. The power is applied at the circumference of the wheel, generally in the direction of a tangent by means of a cord wrapped about the cylinder in order to overcome the resistance or elevate the weight. Here the cord by which the power P acts is applied at the circumference of the wheel, while that of the weight W is applied round the axle or another small wheel attached to the larger, and having the same axis or centre C. Thus BA is a lever moveable about the point C, the power P always acting at the distance BC, and the weight W at the distance CA. Therefore  $P : W :: CA : CB$ . That is, the weight and power will be in equilibrio when the power P is to the weight W reciprocally as the radii of the circles where they act, or as the radius of the axle CA, where the weight hangs, to the radius of the wheel CB, where the power acts; or, as before,  $P : W :: CA : CB$ .

Fig. 552.

1308. If the wheel be put in motion, the spaces moved through being as the circum-

ferences, or as the radii, the velocity of  $W$  will be to the velocity of  $P$  as  $CA$  to  $CB$ ; that is, the weight is moved as much slower as it is heavier than the power. Hence, what is gained in power is lost in time; a property common to machines and engines of every class.

1309. If the power do not act at right angles to the radius  $CB$ , but obliquely, draw  $CD$  perpendicular to the direction of the power, then, from the nature of the lever,  $P : W :: CA : CD$ .

1310. It is to the mechanical power of the wheel and axle that belong all turning or wheel machines of different radii; thus, in the roller turning on the axis or spindle  $CE$  (*fig. 553.*) by the handle  $CBD$ , the power applied at  $B$  is to the weight  $W$  on the roller, as the radius of the roller is to the radius  $CB$  of the handle. The same rule applies to all cranes, capstans, windlasses, &c.; the power always being to the weight as is the radius or lever at which the weight acts to that at which the power acts; so that they are always in the reciprocal ratio of their velocities. To the same principle are referable the gimlet and auger for boring holes.

1311. The above observations imply that the cords sustaining the weights are of no sensible thickness. If they are of considerable thickness, or if there be several folds of them over one another on the roller or barrel, we must measure to the middle of the outermost rope for the radius of the roller, or to the radius of the roller must be added half the thickness of the cord where there is but one fold.

1312. The wheel and axle possesses considerable advantages in point of convenience over the simple lever. A weight can be raised but a little way by a simple lever, whereas by the continued turning of the wheel and axle a weight may be raised to any height and from any depth.

1313. By increasing the number of wheels, moreover, the power may be increased to any extent, making the less always turn greater wheels, by means of what is called *tooth and pinion* work, wherein the teeth of one circumference work in the rounds or pinions of another to turn the wheel. In case, here, of an equilibrium, the power is to the weight as the continual product of the radii of all the axles to that of all the wheels. So if the power  $P$  (*fig. 554.*) turn the wheel  $Q$ , and this turn the small wheel or axle  $R$ , and this turn the wheel  $S$ , and this turn the axle  $T$ , and this turn the wheel  $V$ , and this turn the axle  $X$ , which raises the weight  $W$ ; then  $P : W :: CB \cdot DE \cdot FG : AC \cdot BD \cdot EF$ . And in the same proportion is the velocity of  $W$  slower than that of  $P$ . Thus, if each wheel be to its axle as 10 to 1, then  $P : W :: 1^3 : 10^3$ , or as 1 to 1000. Hence a power of one pound will balance a weight of 1000 pounds; but when put in motion, the power will move 1000 times faster than the weight.

1314. We do not think it necessary to give examples of the different machines for raising weights used in the construction of buildings: they are not many, and will be hereafter named and described.

#### OF THE PULLEY.

1315. A pulley is a small wheel, usually made of wood or brass, turning about a metal axis, and enclosed in a frame, or case, called its *block*, which admits of a rope to pass freely over the circumference of the pulley, wherein there is usually a concave groove to prevent the rope slipping out of its place. The pulley is said to be fixed or moveable as its block is fixed or rises and falls with the weight. An assemblage of several pulleys is called a system of pulleys, of which some are in a fixed block and the rest in a moveable one.

1316. If a power sustain a weight by means of a fixed pulley, the power and weight are

C c 4

Fig. 553.

Fig. 554.

equal. For if through the centre *C* (*fig. 555.*) of the pulley we draw the horizontal diameter *AB*; then will *AB* represent a lever of the first kind, its prop being the fixed centre *C*, from which the points *A* and *B*, where the power and weight act, being equally distant, the power *P* is consequently equal to the weight *W*.

1317. Hence, if the pulley be put in motion, the power *P* will descend as fast as the weight *W* ascends: so that the power is not increased by the use of the fixed pulley, even though the rope go over several of them. It is, nevertheless, of great service in the raising of weights, both by changing the direction of the force, for the convenience of acting, and by enabling a person to raise a weight to any height without moving from his place, and also by permitting a great number of persons to exert, at the same time, their force on the rope at *P*, which they could not do to the weight itself, as is evident in raising the weight, or *monkey*, as it is called, of a pile-driver, also on many other occasions.

Fig. 555.

1318. When a pulley is moveable the power necessary to sustain a weight is equal to the half of such weight. For in this case *AB* (*fig. 556.*) may be con-

Fig. 556.

Fig. 557.

sidered as a lever of the second kind, the weight being at *C*, the power acting at *A*, and the prop or fixed point at *B*. Then, because  $P : W :: CB : AB$  and  $CB = AB$ , we have  $P = \frac{1}{2}W$  or  $W = 2P$ .

1319. From which it is manifest that when the pulley is put in motion the velocity of the power is double that of the weight, inasmuch as the point *P* descends twice as fast as the point *C* and the weight *W* rises. It is, moreover, evident that the fixed pulley *F* makes no difference in the point *P*, but merely changes the motion of it in an opposite direction.

1320. We may hence ascertain the effect of a combination or system of any number of fixed and moveable pulleys, and we shall thereby find that every cord going over a moveable pulley doubles the powers, for each end of the rope bears an equal share of the weight, whilst each rope fixed to a pulley only increases the power by unity. In *fig. 557.*  $P = \frac{1}{4}W$ , and in *fig. 558.*,  $P = \frac{1}{3}W = \frac{w+w+w}{6}$ .

Fig. 558.

#### OF THE WEDGE.

1321. The wedge is a body in the form of a half rectangular prism, in practice usually of wood or metal. *AF* or *BG* (*fig. 559.*) is the breadth of its back, *CE* its height, *CG*, *CB* its sides, and its end, *GBC*, is the terminating surface of two equally inclined planes *GCE*, *BCE*.

1322. When a wedge is in equilibrium, the power acting on the back is to the force acting at right angles to either side as the breadth of the back *AB* (*fig. 560.*) is to the length of the side *AC* or *BC*. For three forces which sustain each other in equilibrium are as the corresponding sides of a triangle drawn perpendicular to the directions in which they act. But *AB* is perpendicular to the force

Fig. 559.

Fig. 560.

acting on the back to drive the wedge forward, and the sides AC, BC are perpendicular to the forces acting on them, the three forces are therefore as AB, AC, BC. Thus, the force on the back, its effect perpendicularly to AC, and its effect parallel to AB, are as the three lines AB, AC, and DC, which are perpendicular to them. Hence the thinner the wedge the greater its effect to split any body or to overcome a resistance against the sides of the wedge.

1323. We are, however, to recollect that the resistance or the forces in question are relative to one side only of the wedge; for if those against both sides are to be reckoned, we can take only half the back AD, or else we must take double the line AC or DC. In the wedge the friction is very great, and at least equal to the force to be overcome, inasmuch as it retains any position to which it is driven, whence the resistance is doubled by the friction. But on the other hand, the wedge has considerable advantage over all the other powers, because of the force of the blow with which the back is struck, a force vastly greater than the dead weight or pressure employed in other machines. On this account it is capable of producing effects vastly superior to those of any other power, such as splitting rocks, raising the largest and heaviest bodies by the simple blow of a mallet; objects which could never be accomplished by any simple pressure whereof in practice application could be made.

#### OF THE SCREW.

1324. The screw is a cord wound in a spiral direction round the periphery of a cylinder, and is therefore a species of inclined plane, whose length is to its height as the circumference of the cylinder is to the distance between two consecutive threads of the screw. It is one of the six mechanical powers used in pressing or squeezing bodies close, and is occasionally used in raising weights.

1325. The screw, then, being an inclined plane or half wedge, the force of a power applied in turning it round is to the force with which it presses upwards or downwards, without estimating friction, as the distance between two threads is to the circumference where the power is applied. For considering it as an inclined plane whose height is the distance between two threads, and its base the circumference of the screw; the force in the horizontal direction being to that in the vertical one as the lines perpendicular to them, namely, as the height of the plane or distance between two threads, is to the base of the plane or circumference of the screw; the power, therefore, is to the pressure as the distance of two threads is to the circumference. But in the application of the screw a handle or lever is used, by means whereof the gain in power is increased in the proportion of the radius of the screw to the radius of the power, that is, the length of the handle, or as their circumferences. Consequently the power is to the pressure as the distance of the threads is to the circumference described by the power. The screw being put in motion, the power is then to the weight which would keep it in equilibrio as the velocity of the latter is to that of the former; and hence their momenta are equal, and produced by multiplying each weight or power by its own velocity.

1326. Thus it is a general property of all the mechanical powers, that the momentum of a power is equal to that of the weight which would keep it in equilibrio, or that each of them is proportional to its velocity.

1327. From the foregoing observations, we may be easily led to compute the force exerted by any machine whose action is exerted through the means of the screw. In *fig. 561.*, representing a press driven by a screw whose threads are each one quarter of an inch apart, let it be turned by a handle or lever 4 feet long from A to B. Then supposing the natural force of a man, by which he can lift, pull, or draw, to be 150 pounds, and that it be required to ascertain with what force the screw will press on the board at D when the man turns with his whole force the handle at A and B; we have AB, the diameter of the power, 4 feet or 48 inches; its circumference, therefore,  $48 \times 3.1416$ , or  $150\frac{1}{2}$  nearly; and the distance of the threads being one quarter of an inch, the power is to the pressure as 1 to  $603\frac{1}{2}$ . But the power is equal to 150 pounds; therefore, as  $1 : 603\frac{1}{2} :: 150 : 90480$ , and the pressure therefore at D is equal to a weight of 90480 pounds, independent of friction.

Fig. 561.

1328. In the endless screw AB (*fig. 562.*), turned by a handle AC of 20 inches radius, the threads of the screw are at a distance of half an inch; and the screw turns a toothed wheel E whose pinion L acts in turning upon another wheel F, and the pinion M of this last wheel acts upon a third wheel G, to the pinion or barrel whereof is hung the weight W. If we would know what weight can be raised through the means of this combination by a man working the handle C, supposing the diameters of the wheels to be 18 inches, and those of the pinions and barrel 2 inches, the teeth and pinions being all similar in size; we

have  $20 \times 3.1416 \times 2 = 125.664$ , the circumference of the power; and  $125.664$  to  $\frac{1}{2}$ , or  $251.328$  to  $1$ , is the force of the screw alone. Again,  $18 : 2$  or  $9 : 1$ , being the proportion of the wheels to the pinions, and there being three of them,  $99 : 1$  or  $729 : 1$  is the power gained by the wheels.

1329. Consequently  $251.328 \times 729$  to  $1$ , or  $183218\frac{1}{2}$  to  $1$  nearly, is the ratio of the power to the weight arising from the joint advantage of the screw and the wheels. The power, however, is  $150$  pounds; therefore  $150 \times 183218\frac{1}{2}$  or  $27482716$  pounds is the weight the man can sustain, equal to  $12269$  tons.

1330. It must be observed, that the power has to overcome not only the weight, but at the same time the friction undergone by the screw, which in some cases is so great as to be equal to the weight itself; for it is sometimes sufficient to sustain the weight when the power is taken off.

Fig. 562.

## OF FRICTION.

1331. Though in a preceding page we have slightly touched on the effect of friction, it is to be kept in mind that the foregoing observations and rules have assumed the mechanical powers to be without weight and friction. This is far from the fact; and, however theoretically true all that has hitherto been advanced, very great allowances must be made in practice when power is applied to mechanical purposes, in which a great portion of their effect is lost by friction, inertia, &c. The word friction, properly meaning the act of one body rubbing on another, is in mechanics used to denote the degree of retardation or obstruction to motion which arises from one surface rubbing against another. A heavy body placed upon another is not in a state of equilibrium between all the forces which act upon it, otherwise it could be moved by the application of the smallest force in a direction parallel to the plane. This want of equilibrium results from unbalanced force occasioned by the friction on a level surface. Now if a new force of equal magnitude be applied to counterpoise such unbalanced force, the body will obey the smallest impulse in such direction, and the force thus employed will exactly measure the retarding force of friction. It has been well observed, that friction destroys, but never generates motion; being therein unlike gravity or the other forces, which, though they may retard motion in one direction, always accelerate it in the opposite. Thus the law of friction violates the law of continuity, and cannot be accurately expressed by any geometrical line, nor by any algebraic formula. The author (Playfair, *Outlines of Natural Philosophy*) just quoted, continues: "Though friction destroys motion and generates none, it is of essential use in mechanics. It is the cause of stability in the structure of machines, and it is necessary to the exertion of the force of animals. A nail or screw or a bolt could give no firmness to the parts of a machine, or of any other structure, without friction. Animals could not walk, or exert their force anyhow, without the support which it affords. Nothing could have any stability, but in the lowest possible situation; and an arch, which could sustain the greatest load when properly distributed, might be thrown down by the weight of a single ounce, if not placed with mathematical exactness at the very point which it ought to occupy."

1332. Many authors have applied themselves to the subject of friction, but the most satisfactory results have attended the investigations of the celebrated Coulomb in its application to practical mechanics; and it is to that author we are indebted for the few following succinct observations.

I. In the friction of wood upon wood in the direction of the fibres after remaining in contact for one or two minutes, the following mean results were obtained: —

Oak against oak	-	$\frac{1}{2.34}$	= friction in parts of the weight.
Oak against fir	-	$\frac{1}{1.50}$	= ditto.
Fir against fir	-	$\frac{1}{1.78}$	= ditto.
Elm against elm	-	$\frac{1}{2.18}$	= ditto.

When oak rubbed upon oak, and the surfaces in contact were reduced to the smallest possible dimensions, the friction was  $\frac{1}{2.36}$ ,  $\frac{1}{2.42}$ ,  $\frac{1}{2.40}$ .

1333. When the friction was across the grain, or at right angles to the direction of the fibres, oak against oak was  $\frac{1}{3\cdot76}$ . The ratios above given are constant quantities, and not dependent upon the velocities, excepting in the case of elm, when the pressures are very small, for then the friction is sensibly increased by the velocity.

1334. (II.) Friction is found to increase with the time of contact. It was ascertained that when wood moved upon wood in the direction of the fibres, the friction gradually increased, and reached its maximum in 8 or 10 seconds. When across the grain of the wood, it took a longer time to reach its maximum.

1335. (III.) For illustration of the friction of metals upon metals after a certain time of rest, the subjoined experiments were made with two flat rulers of iron, 4 feet long and 2 inches wide, attached to the fixed plank of the apparatus used for the investigation. Four other rulers, two of iron and two of brass, 15 inches long and 18 lines wide, were also used. The angles of each of the rulers were rounded off, and the rubbing surfaces of the rulers were 45 square inches.

With iron upon iron and a pressure of 53 lbs., the friction in parts of the pressure was  $\frac{1}{3\cdot5}$ .  
 — — — 453 lbs., — — —  $\frac{1}{5\cdot6}$ .

With iron upon brass and a pressure of 52 lbs., the friction in parts of the pressure was  $\frac{1}{4\cdot2}$ .  
 — — — 452 lbs., — — —  $\frac{1}{4\cdot1}$ .

1336. In these experiments each set gives nearly the same result, though the second pressures are nearly nine times the first; from which we learn that, in metals, friction is independent of the extent of the rubbing surfaces. Coulomb, moreover, found that the friction is independent of the velocities. The ratio of 4 to 1 between the pressure of friction, in the case of iron moving upon brass, is only to be considered accurate when the surfaces are new and very large. When they are very small the ratio varies from 4 to 1 to 6 to 1; but this last ratio is not reached unless the friction has been continued more than an hour, when the iron and brass have taken the highest polish whereof they are susceptible, free of all scratches.

1337. IV. In the friction of oak upon oak, when greased with tallow, which was renewed at every experiment, some days were required for obtaining, when the surfaces were considerable, the maximum of friction or adhesion. It was nearly similar to that without grease, sometimes rather greater. For iron or copper with tallow, during rest, the increase is not so considerable as with oak. At first the friction was  $\frac{1}{11}$  of the weight, besides a small force of a pound for every 30 square inches independent of the weight. The friction after some time changes to  $\frac{1}{10}$  or  $\frac{1}{9}$ . Olive oil alters the condition of the friction to  $\frac{1}{9}$ , and old soft grease to about  $\frac{1}{7}$ .

1338. V. In the case of friction of bodies, oak upon oak for instance, in motion in the direction of its fibres, the friction was nearly constant in all degrees of velocity, though with large surfaces it appeared to increase with the velocities; but when the touching surfaces were very small compared with the pressures, the friction diminished or the velocities increased. For a pressure of 100 to 4000 pounds on a square foot, the friction is about  $\frac{1}{9\cdot5}$ , besides for each square foot a resistance of  $1\frac{1}{2}$  pounds, exclusive of pressure increasing a little with the velocity, occasioned perhaps by a down on the surface. If the surface be very small the friction is lessened. When the narrow surface was cross-grained, the friction was invariably  $\frac{1}{10}$ . In the case of oak on fir, the friction was  $\frac{1}{6\cdot3}$ ; of fir on fir,  $\frac{1}{8}$ ; of elm on elm,  $\frac{1}{10}$ , but varying according to the extent of surface; for iron or copper on wood,  $\frac{1}{13}$ , which was at first doubled by increasing the velocity to a foot in a second, but on a continuance of the operation for some hours it again diminished. For iron on iron,  $\frac{1}{3\cdot55}$ ; on copper,  $\frac{1}{4\cdot15}$ ; after long attrition,  $\frac{1}{8}$  in all velocities. Upon the whole, in the case of most machines,  $\frac{1}{8}$  of the pressure may be considered a fair estimate of the friction.

1339. In the experiments to ascertain the friction of axles, Coulomb used a simple pulley, where the friction of the axis and that of the rigidity of the rope produce a joint resistance. With guaiacum moving upon iron, the friction was  $\frac{1}{5\cdot4}$  or  $\frac{1}{6\cdot4}$  of the weight in all velocities, exclusive of the rigidity of the rope; the mean was  $\frac{1}{6\cdot1}$ , or, with a small weight, a little greater. In the cases of axles of iron on copper,  $\frac{1}{11}$  or  $\frac{1}{11\cdot5}$ , the velocity is small; the friction being always somewhat less than for plane surfaces. With grease, the friction was about  $\frac{1}{7\cdot5}$ . With an axis of green oak or elm, and a pulley of guaiacum, the friction with tallow was  $\frac{1}{12}$ ; without,  $\frac{1}{17}$ ; with a pulley of elm, the quantities in question became  $\frac{1}{13}$  and  $\frac{1}{20}$ . An axis of box with a pulley of guaiacum gave  $\frac{1}{23}$  and  $\frac{1}{14}$ ; with an elm pulley,  $\frac{1}{29}$  and  $\frac{1}{30}$ . An axis of iron and a pulley of guaiacum gave, with tallow,  $\frac{1}{30}$ . The velocity had but small

effect on the rigidity of ropes, except in slightly increasing the resistance when the pressure was small.

1340. The friction and rigidity of ropes was supposed by Amontons and Desaguliers to vary as the diameter as the curvature and as the tension. By Coulomb the power of the diameter expressing the rigidity was found generally to be 1·7 or 1·8, never less than 1·4, and that a constant quantity must be supposed as added to the weight. Wet ropes, if small, are more flexible than such as are dry, and tarred ones stiffer by about one sixth, and in cold weather somewhat more. After rest, the stiffness of ropes increases. A rope of three strands, each having two yarns  $12\frac{1}{2}$  lines in circumference, whose weight was 125 grains, being bent upon an axis 4 inches in diameter, required a constant force of one pound (French) and  $\frac{1}{54\cdot3}$  of the weight to overcome its rigidity. The same rope tarred, required one fifth of a pound and one fiftieth of the weight. When the strands were of fine yarns, the circumference 20 lines, and the weight 347 grains, the rigidity was equal to half a pound and  $\frac{1}{23\cdot1}$  of the weight to move it. With strands of 10 yarns, and a circumference of 28 lines, and a weight of 680 grains to 6 inches, the rigidity of the untarred rope was 2 lbs. and  $\frac{1}{13\cdot33}$  of the weight, and the tarred rope of 3·3 lbs. and  $\frac{1}{10\cdot34}$  of the weight. Experiments which confirmed the above were made on a roller moving on a horizontal plane, while a rope was coiled completely round it, whence an allowance must be made for the friction of the roller on the plane, which varies as its weight and inversely as its diameter. With a roller of guaiacum or lignum vitæ, 3·6 inches in diameter, moving on oak, it was  $\frac{1}{106}$  of the weight; for a roller of elm,  $\frac{2}{3}$  more.

1341. This subject has, we conceive, been pursued as far as is necessary for the architect; seeing that his further investigation of it, should necessity arise, may be accomplished by reference to the works of Amontons, Bulfinger, Parent, Euler, Bossut, and Coulomb, upon whom we have drawn for the information here given. We shall therefore conclude these remarks by subjoining some of the practical results which experiments on animal power afford, extracted from the celebrated Dr. Thomas Young's *Natural Philosophy*, vol. ii.

1342. In comparing the values of the force of moving powers, it is usual to assume an unit, which is considered as the mean effect of the labour of an active man working to the greatest advantage; this on a moderate calculation will be found sufficient to raise 10 lbs. to the height of 10 feet in one second for 10 hours in a day; or 100 lbs. 1 foot in a second, that is 36,000 feet in a day, or 3,600,000 lbs. 1 foot in a day. The following exhibits a tabular view of the immediate force of men, without deduction for friction. Such a day's work is the measuring unit in the third column of the table.

OPERATIVE.	Force.	Continuance.	Day's Work.
A man weighing 133 lbs. French ascended 62 feet French by steps in 34 seconds, but was completely exhausted. <i>Amontons.</i> - - -	2·8	34 sec.	
A sawyer made 200 strokes of 18 French inches each in 145 seconds, with a force of 25 lbs. French. He could not have continued more than 3 minutes. <i>Amontons.</i> - - -	6·0	145 sec.	
A man can raise 60 French lbs. 1 French foot in 1 second for 8 hours a day. <i>Bernoulli.</i>	0·69	8 hours	0·552
A man of ordinary strength can turn a winch with a force of 30 lbs., and with a velocity of $3\frac{1}{2}$ feet in 1 second for 10 hours a day. <i>Desaguliers.</i> -	1·05	10 hours	1·05
Two men working at a windlass, with handles at right angles, can raise 70 lbs. more easily than 1 can raise 30 lbs. <i>Desaguliers.</i> - - -	1·22	—	1·22
A man can exert a force of 40 lbs. for a whole day with the assistance of a fly, when the motion is pretty quick, at about 4 or 5 feet in a second. <i>Desaguliers.</i> But it appears doubtful whether the force is 40 or 20 lbs. - - -	2·00	—	2·00
For a short time, a man may exert a force of 80 lbs. with a fly when the motion is pretty quick. <i>Desaguliers.</i> - - -	3·00	1 sec.	
A man going up stairs ascends 14 metres (35·43 feet) in 1 minute. <i>Coulomb.</i> - - -	1·182	1 min.	

OPERATIVE.	Force.	Continuance.	Day's Work.
A man going up stairs for a day raises 205 kilogrammes (451·64 lbs. averd.) to the height of a kilometre (3280·91 feet). <i>Coulomb.</i>	—	—	0·412
With a spade a man does $\frac{1}{10}$ as much as in ascending stairs. <i>Coulomb.</i>	—	—	0·391
With a winch a man does $\frac{1}{2}$ as much as in ascending stairs. <i>Coulomb.</i>	—	—	0·258
A man carrying wood up stairs raises, together with his own weight, 109 kilogrammes (240·14 lbs. averd.) to 1 kilometre (3280·91 feet). <i>Coulomb.</i>	—	—	0·219
A man weighing 150 French lbs. can ascend by stairs 3 French feet in a second for 15 or 20 seconds. <i>Coulomb.</i>	5·22	20 sec.	
For half an hour 100 French pounds may be raised 1 foot French per second. <i>Coulomb.</i>	1·152	30 min.	
By Mr. Buchanan's comparison, the force exerted in turning a winch being assumed equal to the unit, the force in pumping will be	0·61		
In ringing	1·36		
In rowing	1·43		

1343. Coulomb's maximum of effect is, when a man weighing 70 kilogrammes (154·21 lbs. avoirdupois), carries a weight of 53 (116·76 lbs. avoirdupois,) up stairs. But this appears too great a load.

1344. Porters carry from 200 to 300 lbs., at the rate of 3 miles an hour. Chairmen walk 4 miles an hour with a load of 150 lbs. each; and in Turkey there are found porters who, it is said, by stooping forwards, carry from 700 to 900 lbs. very low on their backs.

1345. The most advantageous weight for a man of common strength to carry horizontally, is 111 pounds; or, if he return unladen, 135. With wheelbarrows, men will do half as much more work, as with hods. *Coulomb.*

The following table exhibits the performance of men by machines.

OPERATIVE.	Force.	Continuance.	Day's Work.
A man raised by means of a rope and pulley 25 lbs. French, 220 French feet in 145 seconds. <i>Amon-</i>	0·436	145 sec.	
<i>tons.</i>			
A man can raise by a good common pump 1 hogshead of water 10 feet high in a minute for a whole day. <i>Desaguliers.</i>	0·875	—	0·875
By the mercurial pump, or another good pump, a man may raise a hogshead 18 or 20 feet in a minute for 1 or 2 minutes	1·61	2 min.	
In pile driving, 55½ French lbs. were raised 1 French foot in 1 second, for 5 hours a day, by a rope drawn horizontally. <i>Coulomb.</i>	0·64	5 hours	0·82
Robison says that a feeble old man raised 7 cubic feet of water 11½ feet in 1 minute for 8 or 10 hours a day, by walking backwards and forwards on a lever	0·837	9 hours	0·753
A young man, the last-named author says, weighing 135 lbs., and carrying 30 lbs., raised 9½ cubic feet 11½ feet high for 10 hours a day, without fatigue	1·106	10 hours	1·106

1346. In respect of the force of horses, we do not think it necessary to do more than observe that the best way of applying their force is in an horizontal direction, that in which a man acts least to advantage. For instance, a man weighing 140 lbs., and drawing a boat along by means of a rope over his shoulders, cannot draw above 27 lbs.; whereas a horse employed for the same purpose can exert seven times that force.

1347. Generally, a horse can draw no more up a steep hill than three men can carry,

that is, from 450 to 750 pounds; but a horse can draw 2000 pounds up a steep hill which is but short. The most disadvantageous mode of applying a horse's force is to make him carry or draw up hill; for if it be steep, he is not more than equal to three men, each of whom would climb up faster with a burden of 100 pounds weight than a horse that is loaded with 300 pounds. And this arises from the different construction of what may be called the two living machines.

1348. Desaguliers observes, that the best and most effectual action of a man is that exerted in rowing, in which he not only acts with more muscles at once for overcoming resistance than in any other application of his strength, but that, as he pulls backwards, his body assists by way of lever.

1349. There are cases in which the architect has to avail himself of the use of horse power; as, for instance, in pugmills for tempering mortar, and occasionally when the stones employed in a building may be more conveniently raised by such means. We therefore think it proper to observe, that, for effectually using the strength of the animal, the *track* or diameter of a walk for a horse should not be less than 25 to 30 feet.

1350. We close this section by observing, more for the curiosity of the thing than for the service it will be to the architect, that some horses have carried 650 or 700 lbs., and that for seven or eight miles, without resting, as their ordinary work; and, according to Desaguliers (*Experiment. Philos.* vol. i.), a horse at Stourbridge carried 11 cwt. of iron, or 1232 lbs., for eight miles.

---

## SECT. IX.

### AUTHORS ON EQUILIBRIUM OF ARCHES.

1351. The construction of arches may be considered in a threefold respect. I. As respects their form. II. As respects the mode in which their parts are constructed. III. As respects the thrust they exert.

1352. The first category involving rather the mode of tracing the right lines and curves whereof their surfaces are composed, has been partially treated of in Section VI. on Descriptive Geometry, and will be further shortly discussed in future pages of this work. The other two points will form the subject of the present section.

1353. The investigation of the equilibrium of arches by the laws of statics does not appear to have at all entered into the thoughts of the ancient architects. Experience, imitation, and a sort of mechanical intuition seem to have been their guides. They appear to have preferred positive solidity to nice balance, and the examples they have left are rather the result of art than of science. Vitruvius, who speaks of all the ingredients necessary to form a perfect architect, does not allude to the assistance which may be afforded in the construction of edifices by a knowledge of the resolution of forces, nor of the aid that may be derived from the study of such a science as Descriptive Geometry, though of the latter it seems scarcely possible the ancients could have been ignorant, seeing how much it must have been (practically, at least) employed in the construction of such vast buildings as the Coliseum, and other similarly curved structures, as respects their plan.

1354. The Gothic architects seem, and indeed must have been, guided by some rules which enabled them to counterpoise the thrusts of the main arches of their cathedrals with such extraordinary dexterity as to excite our amazement at their boldness. But they have left us no precepts nor clue to ascertain by what means they reached such heights of skill as their works exhibit. We shall hereafter offer our conjectures on the leading principle which seems as well to have guided them in their works as the ancients in their earliest, and perhaps latest, specimens of columnar architecture.

1355. Parent and De la Hire seem to have been, at the latter end of the seventeenth century, the first mathematicians who considered an arch as an assemblage of wedge-formed stones, capable of sliding down each other's surfaces, which they considered in a state of the highest polish. In this hypothesis M. de la Hire has proved, in his *Treatise on Mechanics*, printed in 1695, that in order that a semicircular arch, whose joints tend to the centre, may be able to stand, the weights of the *voussoirs* or arch stones whereof it is composed must be to each other as the differences of the tangents of the angles which form each *voussoir*; but as these tangents increase in a very great ratio, it follows that those which form the springings must be infinitely heavy, in order to resist the effects of the superior *voussoirs*. Now, according to this hypothesis, not only would the construction of a semicircular arch be an impossibility, but also all those which are greater or less than a semicircle, whose centre is level with or in a line parallel with the tops of the piers; so that those only would be practicable whose centres were formed by curves forming angles with the piers, such as the parabola, the hyperbola, and the catenary. And we may here remark, that in parabolic and hyperbolic arches, the *voussoir* forming the keystones should be heavier on

greater in height, and that from it the weight or size of the voussoirs should diminish from the keystone to the springing; the catenary being the only curve to which an horizontal *extrados*, or upper side, can be properly horizontal. In the *Memoirs of the Academy of Sciences*, 1729, M. Couplet published a memoir on the thrusts of arches, wherein he adopts the hypothesis of polished voussoirs; but, finding the theory would not be applicable to the materials whereof arches are usually composed, he printed a second memoir in 1730, wherein the materials are so grained that they cannot slide. But in this last he was as far from the truth as in his first.

1356. M. Danisy, a member of the Academy of Montpellier, liking neither of these hypotheses, endeavoured from experiments to deduce a theory. He made several models whose *extrados* were equal in thickness, and divided into equal *voussoirs*, with piers sufficiently thick to resist the thrusts. To ascertain the places at which the failure would take place where the piers were too weak, he loaded them with different weights. From many experiments, in 1732, he found a practical rule for the walls or piers of a cylindrical arch so as to resist the thrust.

1357. Derand had thereupon found one which appears in his *Architecture of Arches*, but it seems to have been empirical. It was nevertheless adopted by Blondel and Deschalles, and afterwards by M. de la Rue.

Gautier, in his *Treatise on Bridges*, adopts one which seems to have had no better foundation in science than Derand's.

1358. At the end of a theoretical and practical treatise on stereotomy by M. Frezier, that author subjoined an appendix on the thrust of arches, which was an extract of what had theretofore been published by M.M. de la Hire, Couplet, Bernouilli, and Danisy, with the applications of the rules to all sorts of arches. He seems to have been the first who considerably extended the view of the subject.

1359. Coulomb and Bossut occupied themselves on the subject. The first, in 1773, presented to the French Academy of Sciences a memoir on several architectural problems, amongst which is one on the equilibrium of arches. The last-mentioned author printed, in the *Memoirs* (1774 and 1776) of the same academy, two memoirs on the theory of cylindrical arches and of domed vaulting, wherein are some matters relating to the cupola of the Pantheon at Paris, whose stability was then a matter of doubt.

1360. In Italy, Lorgna of Verona considers the subject in his *Saggi di Statica Mecanica applicati alle Arti*; and in 1785, Mascheroni of Bergamo published, in relation to this branch of architecture, a work entitled *Nuove Ricerche delle Volte*, wherein he treats of cupolas on circular, polygonal, and elliptical bases.

1361. We ought, perhaps, not to omit a memoir by Bouguer in the Transactions of the French Academy of 1734, *Sur les Lignes Courbes propres a former les Voutes en Dome*, wherein he adduces an analogy between cylindrical and dome vaulting; the one being supposed to be formed by the movement of a catenarian curve parallel to itself, and the other by the revolution of the same curve about its axis.

1362. In this country, the equilibration of the arch, as given by Belidor and others on the Continent, seems to have prevailed, though little was done or known on the subject. Emerson seems to have been the earliest attracted to the subject, and in his *Treatise on Mechanics*, 1743, appears to have been the first who thought, after the Doctors Hooke and Gregory, of investigating the form of the *extrados* from the nature of the curve, in which he was followed by Hutton, who added nothing to the stock of knowledge; an accusation which the writer of this has no hesitation of laying at his own door, as having been the author of a *Treatise on the Equilibrium of Arches*, which has passed through two editions; but who, after much reflection, is now convinced, that, for the practical architect, no theory wherein the *extrados* is merely made to depend on the form of the *intrados* can ever be satisfactory or useful. It is on this account that in the following pages he has been induced to follow the doctrines of Rondelet, as much more satisfactory than any others with which he is acquainted.

1363. The formulæ of Rondelet were all verified by models, and the whole reasoning is conducted upon knowledge which is to be obtained by acquaintance with the mathematical and mechanical portions of the preceding pages. It moreover requires no deep acquaintance with the more abstruse learning requisite for following the subject as treated by later authors.

## OBSERVATIONS ON FRICTION.

1364. I. In order that the stone parallelopiped ABCD (*fig. 563.*) may be made to slide upon the horizontal plane FG, the power which draws or pushes it parallel to this plane, must not be higher than the length of its base AB; for if it acts from a higher point, such as C, the parallelopiped will be overturned instead of sliding along it.

1365. As the effects of the powers P and M are in the inverse ratio of the heights at which they act, it follows that a parallelopiped will slide whenever the force which is necessary to overturn it is greater than

Fig 563.

that necessary to make it slide, and, reciprocally, it will be overturned when less force is necessary to produce that effect than to make it slide.

1366. II. When the parallelopiped is placed on an inclined plane, it will slide so long as the vertical QS drawn from its centre of gravity does not fall without the base AB. Hence, to ascertain whether a parallelopiped ABCD with a rectangular base (*fig. 564.*) will slide down or overturn; from the point B we must raise the perpendicular BE: if it pass out of the centre of gravity, it will slide; if, on the contrary, the line BE passes within, it will overturn.

1367. If the surfaces of stones were infinitely smooth, as they are supposed to be in the application of the principles of mechanics, they would begin to slide the moment the plane upon which they are placed ceases to be perfectly horizontal; but as their surfaces are full of little inequalities which catch one another in their positions, Rondelet found, by repeated experiments, that even those whose surfaces are wrought in the best manner do not begin to slide upon the best worked planes of similar stone to the solids until such planes are inclined at angles varying from 28 to 36 degrees. This difficulty of moving one stone upon another increases as the roughness of their surfaces, and, till a certain point, as their weight: for it is manifest, 1st, That the rougher their surfaces, the greater are the inequalities which catch one another. 2d. That the greater their weight, the greater is the effort necessary to disengage them; but as these inequalities are susceptible of being broken up or bruised, the maximum of force wanting to overcome the friction must be equal to that which produces this effect, whatever the weight of the stone. 3d. That this proportion is rather as the hardness than the weight of the stone.

1368. In experiments on the sliding of hard stones of different sizes which weighed from 2 to 60 lbs., our author found that the friction which was more than half the weight for the smaller was reduced to a third for the larger. He remarked that after each experiment made with the larger stones a sort of dust was disengaged by the friction. In soft stones this dust facilitated the sliding.

1369. These circumstances, which would have considerable influence on stones of a great weight, were of little importance in the experiments which will be cited, the object being to verify upon hard stones, whose mass was small, the result of operations which the theory was expected to confirm. By many experiments very carefully made upon hard freestone well wrought and squared, it was found, 1st, That they did not begin to slide upon a plane of the same material equally well wrought until it was inclined a little more than 30 degrees. 2d. That to drag upon such stone a parallelopiped of the same material, a little more than half its weight was required. Thus, to drag upon a level plane a parallelopiped 6 in. long, 4 in. wide, and 2 in. thick, weighing 4 lbs. 11 oz., (the measures and weights are French, as throughout\*), it was necessary to employ a weight equal to 2 lbs. 7 oz. and 4 drs. 3d. That the size of the rubbing surface is of no consequence, since exactly the same force is necessary to move this parallelopiped upon a face of two in. wide as upon one of 4.

1370. Taking then into consideration that by the principles of mechanics it is proved, that to raise a perfectly smooth body, or one which is round upon an homogeneous plane inclined at an angle of 30 degrees, a power must be employed parallel to the plane which acts with a force rather greater than half its weight, we may conclude that it requires as much force to drag a parallelopiped of freestone upon an horizontal plane of the same material as to cause the motion up an inclined plane of 30 degrees of a round or infinitely polished body.

1371. From these considerations in applying the principles of mechanics to arches composed of freestone well wrought, a plane inclined at 30 degrees might be considered as one upon which the voussoirs would be sustained, or, in other words, equivalent to an horizontal plane.

1372. We shall here submit another experiment, which tends to establish such an hypothesis. If a parallelopiped C (*fig. 565.*) of this stone be placed between two others, BD, RS, whose masses are each double, upon a plane of the same stone, the parallelopiped C is sustained by the friction alone of the vertical surfaces that touch it. This effect is a consequence of our hypothesis; for, the inequalities of the surfaces of bodies being stopped by one another, the parallelopiped C, before it can fall, must push aside the two others, BD, RS, by making them slide along the horizontal plane of the same material, and for that purpose a force must be employed equal to double the weight sustained.

Fig. 565.

\* The Paris pound = 7561 Troy grains.

Ounce = 472.5625.

Dram or gros = 59.0703.

Grain = 0.8204.

And as the English avoirdupois pound = 7000 Troy grains, it contains 8538 Paris grains.  
The Paris foot of 12 inches = 12.7977 English inches.

1373. If to this experiment the principles of mechanics be applied, considering the plane of 30 degrees inclination as a horizontal plane, the vertical faces ED FR may be considered as inclined planes of 60 degrees. On this hypothesis it may be demonstrated by mechanics, that to sustain a body between two planes forming an angle of 60 degrees (*fig. 566.*), the resistance of each of these planes must be to half the weight sustained as HD is to DG, as the radius is to the sine of 30 degrees, or as 1 is to 2.

## EQUILIBRIUM OF ARCHES.

1374. The resistance of each parallelopiped represented by the prism ABDE (*fig. 565.*) being equal to half their weight, it follows that the weight to be sustained by the two prisms should equal one quarter of the two parallelopipeds taken together, or the half of one, which is confirmed by the experiment. This agreement between theory and practice determined Rondelet to apply the hypothesis to models of vaults composed of voussoirs and wedges, disunited, made of freestone, with the utmost exactness, the joints and surfaces nicely wrought, as the parallelopipeds in the preceding example.

1375. The first model was of a semicircular arch 9 inches diameter, comprised between two concentric semi-circumferences of circles 21 lines apart. It was divided into 9 equal voussoirs. This arch was 17 lines deep, and was carried on piers 2 inches and 7 lines thick. It was found, by gradually diminishing the piers, which were at first 2 inches and 10 lines thick, that the thickness first named was the least which could be assigned to resist the thrust of the voussoirs.

1376. The model in question is represented in *fig. 567.*, whereon we have to observe, — 1st. That the first voussoir, I, being placed on a level joint, not only sustains itself, but is able to resist by friction an effort equal to one half of its weight. 2d. That the second voussoir, M, being upon a joint inclined 20 degrees, will also, through friction, sustain itself; and that, moreover, these two voussoirs would resist, previous to giving way on the joint AB, an horizontal effort equal to one half of their weight. 3d. That the third voussoir, N, standing on a joint inclined at 40 degrees, would slide if it were not retained by a power PN acting in an opposite direction. 4th. That taking, according to our hypothesis, an inclined plane of 30 degrees, whereon the stones would remain in equilibrium as an horizontal one, the inclined point of 40 degrees may be considered as an inclined plane of 10 degrees, supposing the surfaces infinitely smooth. 5th. That the effort of the horizontal power which holds this voussoir in equilibrium upon its joints will be to its weight as the sine of 10 degrees is to its cosine, as we have, in the section on Mechanics, previously shown. (1255 et seq.)

1377. The model of the vault whereon we are speaking being but 9 inches, or 108 lines in diameter, by 21 lines for the depth of the voussoirs, that is, the width between the two concentric circumferences, its entire superficies will be 4257 square lines, which, divided by 9, gives for each voussoir 473 square lines. Then, letting the weight of each voussoir be expressed by its superficies, and calling P the horizontal power, we have

$$P : 473 :: \sin. 10^\circ : \cosin. 10^\circ;$$

$$\text{Or, } P : 473 :: 17365 : 98481; \text{ which gives } P = 834 \frac{1}{10}.$$

The fourth voussoir, being placed upon a bed inclined at 60 degrees, will be considered as standing on a plane inclined only at 30 degrees, which gives, calling Q the horizontal power which keeps it on its joint, —

$$Q : 473 :: \sin. 30^\circ : \cosin. 30^\circ.$$

$$\text{Or, } Q : 473 :: 50000 : 86603 = 273 \frac{3}{10}.$$

1378. The half-keystones, being placed on a joint inclined 80 degrees, are to be considered as standing on an inclined plane of 50, the area of the half key which represents its weight being 236  $\frac{1}{2}$ . If we call R the horizontal power which sustains it on its joint, we shall have the proportion

$$R : 236 \frac{1}{2} :: \sin. 50 : \cosin. 50;$$

$$\text{or, } R : 236 \frac{1}{2} :: 76604 : 64279; \text{ which gives } R = 281 \frac{2}{10}.$$

1379. Wishing to ascertain if the sum of these horizontal efforts, which were necessary to keep on their joints the two voussoirs N, O, and the half-keystone, was capable of thrusting away the first voussoir upon its horizontal joint AB, the half arch was laid down upon a level plane of the same stone without piers, and it was proved that to make it give way an horizontal effort of more than 16 ounces was required, whilst only 10 were neces-

sary to sustain the half-keystone and the two voussoirs N, O. The two halves of the arches united bore a weight of 5 lbs. 2 oz. before the first voussoirs gave way.

1380. To find the effect of each of these voussoirs when the arch is raised upon its piers, let fall from the centres of gravity N, O, S of these voussoirs the perpendiculars Nn, Oo, Ss, in order to obtain the arms of the levers of the powers P, Q, R, which keep them in their places, tending at the same time to overturn upon the fulcrum T the pier which carries the half arch, and we have their effort—

$$P \times Nn + Q \times Oo + R \times Ss.$$

The height of the pier being 195 lines, we have

$$Nn = 244.94$$

$$Oo = 256.26$$

and  $Ss = 260.50$ , whence we have

$$\text{The effort } P \times Nn = 83.4 \times 244.94, \text{ which gives } 20427.996$$

$$Q \times Oo = 273.3 \times 256.26 \dots\dots\dots 70035.858$$

$$R \times Ss = 281.9 \times 260.50 \dots\dots\dots 73434.950$$

Total effort in respect of the fulcrum, 163898.804

1381. The pier resists this effort, 1st, by its weight or area multiplied by the arm of the lever determined by the distance Tu from the fulcrum T to the perpendicular let fall from the centre of gravity G upon the base of the pier. 2d. By the weight of the half arch multiplied by the arm of its lever VY determined by the vertical LY let fall from the centre of gravity L, and which becomes in respect of the common fulcrum T = Tt or VB - BY, in order to distinguish BY, which indicates the distance of the centre of gravity of the half arch (and which is supposed known because it may be found by the rules given in 1275. et seq.) from the width VB that the pier ought to have to resist the effort of the half arch sought. In order to find it, let P, the effort of the arch above found, be 163898.804.

Let the height of the pier = a

The width sought = x

The weight of the half arch = b

The part BY of its arm of lever = c

1382. The area of the pier which represents its weight multiplied by the arm of the lever will be  $ax \times \frac{x}{2} = \frac{axx}{2}$ . That of the half arch multiplied by its arm of lever will be shown by VB + BY, where  $x + c$  will be  $bx + bc$ , whence the equation  $P = \frac{axx}{2} + bx + bc$ , which we have to solve.

Now first we have  $\frac{axx}{2} + bx = P - bc$ .

Multiplying all the terms by  $\frac{2}{a}$   $\left\{ \begin{array}{l} xx + \frac{2bx}{a} = \frac{2p-2bc}{a} \end{array} \right.$ , an expression in which  $x$  is raised to to eliminate  $xx$ , we have the second power; but as  $xx + \frac{2bx}{a}$  is not a perfect square, that is to say, it wants the square of half the known quantity  $\frac{2b}{a}$  which multiplies the second term; by adding this square, which is  $\frac{bb}{aa}$ , to each side of the equation, we have  $xx + \frac{2bx}{a} + \frac{bb}{aa} = \frac{2p-2bc}{a} + \frac{bb}{aa}$ . The first member by this means having become a perfect square whose root is  $a + \frac{b}{a}$ , we shall have  $x + \frac{b}{a} + \sqrt{\frac{2p-2bc}{a} + \frac{bb}{aa}}$ , which becomes, by transferring  $\frac{b}{a}$  to the other side of the equation,  $x = \sqrt{\frac{2p-2bc}{a} + \frac{bb}{aa}} - \frac{b}{a}$ , in which  $x$  being only in the first member of the equation, its value is determined from the known quantities on the other side. Substituting, then, the values of the known quantities, we have

$$x = \sqrt{\frac{163898.804 \times 2 - 2128 \times 2 \times 12\frac{1}{2}}{195} + \frac{2128}{195} \times \frac{2128}{195} - \frac{2128}{195}}$$

which gives  $x = 28\frac{1}{2}$  lines instead of 2 inches and 5 lines, which was assigned to the piers that they might a little exceed equilibrium in their stability.

*Proof of the above Method by another Method of estimating Friction.*

1383. A proof of the truth of the hypothesis in the preceding section is to be found in the method proposed by Bossut in his *Treatise on Mechanics*.

Let the voussoir N (fig. 568.) standing on an inclined plane be sustained by a power Q acting horizontally. From the

Fig. 568.

centre of gravity let fall the vertical  $Nn$ , which may be taken to express the weight of the voussoir. This weight may be resolved into two forces, whereof one,  $Nc$ , is parallel to the joint, and the other  $Na$  is perpendicular to it. In the same manner the power  $Q$  expressed by  $QN$  in its direction may be resolved into two forces, whereof  $Nf$  will be parallel to the joint and the other  $Nd$  perpendicular to it. Producing the line from the joint  $HG$ , drawing the horizontal line  $GI$  and letting fall the vertical  $HI$ , consider the line  $HG$  as an inclined plane whose height is  $HI$  and base  $IG$ . Then the force  $Nc$  with which the voussoir will descend will be to the weight as the height  $HI$  of the inclined plane is to its length  $HG$ . Calling  $p$  the weight of the voussoir, we then have  $Nc = p \times \frac{HI}{HG}$ , and the force  $Na$  which presses against the plane as the base of the plane  $IG$  is to its length, which gives the force  $Na = p \times \frac{IG}{HG}$ .

1384. Considering, in the same way, the two forces of the power  $Q$  which retain the voussoir on the inclined plane, we shall find the parallel force  $Nf = Q \times \frac{IG}{GH}$ , and the perpendicular force  $Nd = Q \times \frac{IH}{GH}$ . The force resulting from the two forces  $Na$ ,  $Nd$ , which press against the joint, will be expressed by  $p \times \frac{IG}{HG} + Q \times \frac{H}{GH}$ ; and as the voussoir only begins to slide upon a plane whose inclination is greater than 30 degrees, the friction will be to the pressure as the sine of 30 degrees is to its cosine, or nearly as 500 is to 866, or  $\frac{500}{866}$  of its expression. Calling this ratio  $n$ , we shall, to express the friction, have

$$\left( p \times \frac{IG}{GH} + Q \times \frac{IG}{GH} \right) \times n.$$

As the friction prevents the voussoir sliding on its joint, in a state of equilibrium, we shall have the force  $Nf$  equal to the force  $Nc$ , less the friction; from which results the equation—

$$Q \times \frac{IG}{HG} = p \times \frac{HI}{HG} - \left( p \times \frac{IG}{GH} + Q \times \frac{IH}{GH} \right) \times n.$$

All the terms of which equation having the common divisor  $HG$ , it becomes—

$$Q \times IG = p \times HI - (p \times IG + Q \times IH) \times n;$$

and, bringing the quantities multiplied by  $Q$  to the same side of the equation, we have

$$Q \times IG + (Q \times IH) \times n = p \times HI - (p \times IG) \times n; \text{ which becomes}$$

$$Q \times (IG + n \times IH) = p \times (HI - n \times IG); \text{ whence results}$$

$$Q = p \times \frac{HI - n \times IG}{IG + n \times IH}, \text{ which is the formula for each voussoir, substituting the values for the expression.}$$

1385. Thus for the third voussoir  $N$  (*fig.* 567.) placed on an inclined plane of 40 degrees,  $HI$  which represents the sine of the inclination will be 643, and its cosine represented by  $IG$ , 766, the expression of the friction  $n$  will be  $\frac{500}{866}$ , or  $\frac{15}{26}$  nearly. The weight of the voussoir expressed by its area will be 473, which several values being substituted in the formula, we have

$$Q = 473 \times \frac{643 - \frac{15}{26} \times 766}{766 + \frac{15}{26} \times 643};$$

which gives  $Q = 83.6$ , the expression of the horizontal force  $P$ , which will keep the voussoir  $N$  in equilibrium on its joint instead of 83.4, which was the result of the operation in the preceding subsection.

1386. The same formula  $Q = p \times \frac{HI - n \times IG}{IG + n \times IH}$  gives for the voussoir  $M$  on an inclined joint of 60 degrees, whose sine  $HI$  is 866 and cosine  $IG$  500,  $Q = 473 \times \frac{866 - \frac{15}{26} \times 500}{500 + \frac{15}{26} \times 866} = 273.4$ ; instead of 273.3, which was the result of the operation in the preceding section.

1387. For the half-keystone, the sine  $HI$ , being of 80 degrees, will be expressed by 985, and its cosine  $IG$  by 174; the half-keystone by 236 $\frac{1}{2}$ , and the friction by  $\frac{15}{26}$ .

The formula now will be  $Q = 236\frac{1}{2} \times \frac{985 - \frac{15}{26} \times 174}{174 + \frac{15}{26} \times 985}$ , which gives  $Q = 282.2$ , instead of 281 $\frac{9}{10}$  found by the other method. These slight differences may arise from suppressing the two last figures of the sines, and some remainders of fractions which have been neglected. Multiplying these values of the powers which keep the voussoirs in equilibrium upon their beds by the several arms of the levers, as in the preceding calculations, their energy will be as follows:—

$$\text{For the voussoir } N, \quad 83.6 \times 244.94 = 20476.98$$

$$\text{— } O, \quad 273.4 \times 256.26 = 70061.48$$

$$\text{— } S, \quad 282.2 \times 260.50 = 73313.10$$

For the total force in respect of the fulcrum  $T = 163851.56$ .

Which is the value of  $p$ , and being substituted for it in the formula  $x = \sqrt{\frac{2p-2bc}{a} + \frac{hb}{aa} - \frac{b}{a}}$ .

as well as the values of the other letters, which are the same as in the preceding example, we have

$$x = \sqrt{\frac{163851 \cdot 56 \times 2 - 2128 \times 2 \times 124}{195}} + \frac{2128}{195} \times \frac{2128}{195} - \frac{2128}{195} = 28 \cdot 16 \text{ lines}$$

for the thickness of the piers, instead of  $28\frac{1}{2}$  lines found by the preceding operation.

*Application of the Principles in the Model of a straight Arch.*

1388. The second model to which the application of the preceding methods was made was a straight arch of the same sort (*fig. 569.*), whose opening between the piers was 9 inches. The arch was 21 lines high and 18 lines thick. It was divided into 9 wedges, whose joints were concentric. To determine the section of the joints, the diagonal FG was drawn on the face of the half arch, and from its extremity F touching the pier, the perpendicular FO meeting O in the vertical, passing through the middle of the opening of the piers, all the sections meeting in this point O. Each of the sections of the piers which support the arch forms an angle of  $21^\circ 15'$  with the vertical, and of  $68^\circ 45'$  with the horizon.

1389. In considering each of the wedges of the half arch as in the preceding method, it will be found that in order to retain the voussoir A on the joint IF (of the pier) which forms with the horizontal line NF an angle of  $68^\circ 45'$ , we have

For the horizontal force	-	-	-	217·50
second B	-	-	-	254·33
third C	-	-	-	298·75
fourth D	-	-	-	354·66
half-keystone	-	-	-	212·83
Total	-	-	-	1338·07

The height of the piers being 195 lines to the underside of the arch, and 216 to the top of the extrados, it follows that the arm of the lever, which is the same for all the wedges, is 206 $\frac{1}{2}$ , from which we derive for the thrust *p* of the formula,

$$x = \sqrt{\frac{2p-2bc}{a} + \frac{bb}{aa} - \frac{a}{b}}$$

$$= 1338 \cdot 07 \times 206 \cdot 33 = 276084 ;$$

*b* which expresses the area of the half arch = 1219 $\frac{1}{2}$ ; *c* which expresses the distance of its centre of gravity from the vertical *Fa* = 24, and the height of the pier *a* = 216. Now, substituting these values in the formula, we shall have

$$a = \sqrt{\frac{276084 \times 2 - 2439 \times 24}{216} + \frac{1219\frac{1}{2} \times 1219\frac{1}{2}}{216 \times 216} - \frac{1219\frac{1}{2}}{216}} = 42\frac{1}{2} \text{ lines.}$$

Experiment gives 44 lines for the least width of the piers upon which the model will stand. But it is right to observe that from the impossibility of the joints being perpendicular to the intrados, the forces of the wedges press in a false direction on each other, as will be seen by the lines *Fa*, *1e*, *2e*, *3g*, perpendicular to the joints against which the forces are directed, so that such an arch will only stand when the perpendicular FG does not fall within the thickness of the arch; and, indeed, this sort of arch is only secure when it comprises an arc whose thickness is equal to the section upon the piers IF, as shown in *fig. 570.*

*Observations on the Way in which Stones forming an Arch act to support one another.*

1390. Let the semicircular arch AHCDNB (*fig. 571.*) consist of an infinite number of voussoirs acting without friction, and only kept in their places by their mutual forces acting on each other. It will follow —

1. That the first voussoir, represented by the line AB, having its joints sensibly parallel and horizontal, will act with its whole weight in the vertical direction IE to strengthen the pier.

2. That the vertical voussoir CD, which represents the keystone, having also its joints sensibly parallel, will act with its whole weight horizontally to overturn the semi-arches and piers which carry them.

3. That all the other voussoirs between these two extremes will act with the compound forces  $Gn$ ,  $nm$ ,  $ml$ ,  $Kl$ ,  $Kh$ ,  $hg$ ,  $gf$ ,  $fT$ , which may each be resolved into two others, whereof one is vertical and the other horizontal: thus the compound force  $Kh$  is but the result of the vertical force  $4h$ , and the horizontal force  $4K$ .

4. That the vertical force of each voussoir diminishes from T to G, where, for the keystone CD, it becomes nothing, whilst the horizontal forces continually increase in an inverse ratio; so that the voussoir HN, which is in the middle, has its vertical and horizontal forces equal.

5. That in semi-circular arches whose extradoses are of equal height from their intradoses, the circumference passing through the centre of gravity of the voussoirs may represent the sum of all the compound forces with which the voussoirs act upon one another in sustaining themselves, acting only by their gravity.

6. That if from the points T and G the vertical TF and horizontal GF be drawn meeting in the point F, the line TF will represent the sum of the vertical forces which assist the stability of the pier, and FG the sum of the horizontal forces which tend to overthrow it.

7. That if through the point K the horizontal line IKL be drawn between the parallels FT and CO, the part IK will represent the sum of the horizontal forces of the lower part AHNB of the vault, and KL those of the upper part HCDN.

8. The lower voussoirs between T and K being counterpoised by their vertical forces, the part of the arch AHNB will have a tendency to fall inwards, turning on the point B, whilst the voussoirs between K and G being counterpoised by their horizontal forces, the part HCDN of the arch will re-act upon the lower part by its tendency to turn upon the point A.

9. The horizontal forces of the upper part of the arch shown by KL acting from L towards K, and those of the lower part shown by IK opposite in direction to the former, that is, from I to K, being directly opposed, would counterpoise each other if they were equal, and the arch would have no thrust; but as they are always unequal, it is the difference of the forces which occasions the thrust, and which acts in the direction of the strongest power.

10. If we imagine the width BO of a semi-arch constantly to diminish, its height remaining the same, the sum of the horizontal forces will diminish in the same ratio, so that when the points B and O are common, the horizontal force being annihilated, nothing remains but the vertical force, which would act only on the pier, and tend to its stability, thrust vanishing, because, instead of an arch, it would, in fact, be nothing more than a continued pier.

11. If, on the contrary, the height OD diminishes, the width BO remaining the same, the curve B and D would, at last, vanish into the right line BO, and the arch would become a straight one. In this case, the vertical forces which give stability to the pier being destroyed, all that remains for sustaining the arch are the horizontal forces which will act with the whole weight of the arch; whence this species of arches must be such as exert most thrust, and circular arches hold a middle place between those which have no thrust, and flat arches, whose thrust is infinite, if the stones whereof they are formed could slide freely on one another, and their joints were perpendicular to their lower surfaces, as in other arches.

12. The inconveniences which result from making the joints of flat arches concentric have been before noticed. If the stones could slide freely on one another, as they only act in a false direction, their forces could never either balance or destroy one another.

13. A vast number of experiments made by Rondelet, upon fifty-four models of arches of different forms and extradoses, divided into an equal and unequal number of voussoirs, showed that the voussoirs acted rather as levers than as wedges, or as bodies tending to slide upon one another.

14. As long as the piers are too weak to resist the thrust of the voussoirs, many of them unite as one mass, tending to overturn them on a point opposite to the parts where the joints open.

15. Arches whose voussoirs are of even number exert more thrust than those which are of unequal number, that is, which have a keystone.

16. In those divided into uneven numbers and of unequal size, the larger the keystone the less is their thrust, so that the case of the greatest thrust is when a joint is made at the vertex, as in the case of arches whose voussoirs are divided into equal numbers.

17. A semicircular arch divided into four equal parts has more thrust than one divided into nine equal voussoirs.

18. Arches including more than a semicircle have less thrust than those of a similar span, the intradoses and extradoses being of similar forms.

19. Thrust does not increase as the thickness of an arch increases; so that, *ceteris paribus*, an arch of double the thickness has not double the thrust.

20. A semicircular arch whose extrados is equally distant throughout from, or, in other words, concentric with, the intrados, when divided into four equal parts, will only stand when its depth is less than the eighteenth part of its diameter, even supposing the abutments immovable.

21. Whenever, in an arch of voussoirs of equal depth, a right line can be drawn from its outer fulcrum to the centre of the extrados of the keystone (*fig. 572.*), fracture does not occur in the middle of the haunches if the piers are of the same thickness as the lower part of the arch.

22. Arches whose thickness or depth diminishes as they rise to the vertex have less thrust than those whose thickness is equal throughout.

23. Semicircular and segmental arches whose extrados is an horizontal line have less thrust than others.

24. As long as the piers in the models were too weak to resist the thrust, it was possible to keep them in their places by a weight equal to double the difference between the thrust and resistance of one pier, acting by a string suspended passing through the joints in the middle of the haunches, or by a weight equal to that difference placed above each middle joint of the arches, as in *fig. 572.*

From these experiments and many others, a formula has been deduced to determine the thickness of piers of cylindrical arches of all species whose voussoirs are of equal depth, whatever their forms; and to this we shall now introduce the reader.

Fig. 572.

### Method.

1391. Having described the mean circumference  $GKT$  (*figs. 573, 574.*), from the points  $G$  and  $T$  draw the tangents to the curve meeting in the point  $F$ . From this point draw the secant  $FO$  cutting it in the point  $K$ . This point is the place of the greatest effort, and of the consequent failure, if the thickness of the piers is too weak to resist the thrust.

1392. Through the point  $K$ , between the parallels  $TF$  and  $GO$ , draw the horizontal line  $IKL$ , which will represent the sum of the horizontal forces as will the vertical  $TF$  express the vertical forces; the mean circumference  $GKT$  will express the compound forces.

1393. The arches having an equal thickness throughout, the part  $IK$  of the horizontal line multiplied by the thickness of the arch will express the horizontal effect of the lower part of either arch, and  $KL$  multiplied by the same thickness will express that of the upper part. These two forces acting in opposite directions will partly destroy each other; thus transferring  $IK$  from  $K$  to  $m$ , the difference  $mL$  multiplied by the thickness of the vault will be the expression of the thrust. This force acting at the point  $K$  in the horizontal direction  $KH$ , the arm of the lever is determined by the perpendicular  $PH$  raised from the fulcrum  $P$  of the lever to the direction of the thrust, so that its effort will be expressed by  $mL \times AB \times PH$ .

This will be resisted —

1. By its weight represented by the surface  $EP \times PR$  multiplied by the arm of the lever  $PS$ , determined by a vertical let fall from the centre of gravity  $Q$ , which gives for the resistance of the pier the expression  $EP \times PR \times PS$ .

2. By the sum of the vertical efforts of the upper part of each arch, represented by  $MK \times AB$  acting at the point  $K$ , the arm of their lever in respect of the fulcrum  $P$  of the pier being  $KH$ .

3. By the sum of the vertical efforts of the lower part represented by  $IT$  multiplied by  $AB$  acting on the point  $T$  has for the arm of its lever  $TE$ . Hence, if equilibrium exist,

$$mL \times AB \times PH = PE \times PR \times PS + MK \times AB \times KH + IT \times AB \times TE.$$

But as in this equation neither  $PR$  ( $= BE$ ) nor  $PS$  nor  $KH$  nor  $TE$  is known, we must resort to an algebraic equation for greater convenience, in which

The effect of the thrust in the expression $mL \times AB$	$= p$
The height of the pier $PE$	$= a$
$EH = TI = KL = KV$	$= d$
$PH$	$= a + d$
$EB = PR$	$= x$

Fig. 573.

Fig. 574.

PS	-	-	-	-	-	$=\frac{x}{2}$
The sum of the vertical forces of the upper part or						
MK $\times$ AB	-	-	-	-	-	$=m$
The sum of the forces of the lower part IT $\times$ AB	-	-	-	-	-	$=n$
The part iK of the horizontal IKL	-	-	-	-	-	$=c$
TB equal to half the thickness of the arch	-	-	-	-	-	$=e$
The arm of the lever KH	-	-	-	-	-	$=c \times x$
That of TE	-	-	-	-	-	$=x-e$

Thus the first equation becomes  $pa + pd = \frac{axx}{2} + m(c \times x) + n(x-e)$ ,

Or  $pa \times pd = \frac{axx}{2} + mx + mc + nx - ne$ .

Transferring the unknown quantities to the second side of the equation, we shall

have  $\frac{axx}{2} + mx + nx = pa + pd + ne - mc$ .

Multiply all the terms by 2, and divide by  $a$ , in order to get rid of  $xx$ , and we

have  $xx + \frac{2(m+n)x}{a} = 2p + \frac{2pd+2nc-2mc}{a}$ ;

Making  $m+n=b$ , and adding to each member  $\frac{bb}{aa}$  for the purpose of extracting the root of the first member,

We have  $xx + \frac{2bx}{a} + \frac{bb}{aa} = 2p + \frac{2pd+2nc-2mc}{a} + \frac{bb}{aa}$ .

Extracting the root,  $x + \frac{b}{a} = \sqrt{2p + \frac{2pd+2nc-2mc}{a} + \frac{bb}{aa}}$ ;

And lastly,  $x = \sqrt{2p + \frac{2pd+2nc-2mc}{a} + \frac{bb}{aa}} - \frac{b}{a}$ .

1394. This last equation is a formula for finding the thickness of all sorts of arches whose voussoirs are of equal depth, which we will now apply to *fig. 573*. The model was 36 inches and 3 lines in span. The arch consisted of two concentric circles, and it was divided into four equal parts, a vertical joint being in the middle, the two others being inclined at angles of 45 degrees. The piers whereon it was placed were 40 inches and 4 lines high, and on a very exact measurement the values were as follow:—

PE ( $a$ in the formula) was	-	-	-	-	-	40.333
EH = TI = KL = KV ( $d$ in the formula)	-	-	-	-	-	13.876
ML $\times$ AB ( $p$ in the formula) representing the thrust or $8.127 \times 3$	-	-	-	-	-	24.381
$2p$	-	-	-	-	-	48.762
$2pd = 48.762 \times 13.876$	-	-	-	-	-	676.621
$2MK \times AB \times KH$ represented by $2mc$ ( $= 5.749 \times 3 \times 4.249$ )	-	-	-	-	-	73.282
$2ne$ , which is IT $\times$ AB $\times$ AB ( $= 13.876 \times 3 \times 3$ )	-	-	-	-	-	124.824
$b = m + n = (MK + IT) \times AB$ ( $= 19.625 \times 3$ )	-	-	-	-	-	58.875
$a = EP$ , the height of the pier being 40.333, $\frac{b}{a}$ will be $\frac{58.875}{40.333}$ or	-	-	-	-	-	1.459
$\frac{bb}{aa}$	-	-	-	-	-	2.128

Substituting these values in the formula  $x = \sqrt{2p + \frac{2pd+2nc-2mc}{a} + \frac{bb}{aa}} - \frac{b}{a}$ ,

we have  $x = \sqrt{48.762 + \frac{676.621 + 124.824 - 73.282}{40.333} + 2.128} - 1.459$ ;

which gives  $x = 5.8$ , or 5 inches  $9\frac{1}{2}$  lines for the thickness of the piers to resist the thrust of the arch, supposing it to be perfectly executed. But, from the imperfection of the execution of the model, it was found that the piers required for resisting the thrust a thickness of 6 inches and 3 lines.

1395. When the piers of the model were made 7 $\frac{1}{2}$  inches thick the arch on its central joint was found capable of supporting a weight of three pounds, being equal to an addition of 8 superficial inches beyond that of the upper parts of the arch which are the cause of the thrust, and this makes the value of  $2p$  in the formula 56.762 instead of 48.762,

and changes the equation to  $x = \sqrt{56.762 + \frac{787.629 + 124.828 - 86.458}{40.333} + 2.430} - 1.55$ ; from which we should obtain  $x = 7.366$  inches, or 7 inches  $3\frac{1}{2}$  lines, exhibiting a singular agreement between theory and practice. Rondelet gives another method of investigating the preceding problem, of which we do not think it necessary to say more than that it agrees with that just exhibited so singularly that the result is the same. It is dependent on the places of the centres of gravity, and therefore not so readily applicable in practice as that which has been just given.

#### Second Experiment.

1396. *Fig. 567.*, in a preceding page, is the model of an arch in freestone, which has been before considered. It is divided into nine equal voussoirs, whose depth to the extrados is 21 lines, and whose interior diameter is 9 inches.

1397. Having drawn the lines heretofore described, we shall find  $mL \times AB$  expressed in the formula by

$p = 26.7 \times 21$ , which gives	-	-	-	560.70
And for $2p$	-	-	-	1121.40
$EH = TI = KL = KV$ , expressed by $d$ , will be	-	-	-	45.60
Hence $2pd$	-	-	-	5113.584
$2ne$ , which is twice the vertical effort of the lower part of the arch, multiplied by $\frac{1}{2} AB$ , will be $45.6 \times 21 \times 21$ , which gives	-	-	-	20109.60
$2me$ , which indicated twice the vertical effort of the upper part, multiplied by $iK$ , will be $18.9 \times 21 \times 2 \times 8.4$ , which gives	-	-	-	6667.92
$a$ , which represents the height of the piers, being 195, and $b = m + n = 64.5 \times 21 = 1354.5$ , $\frac{b}{a}$ will become $\frac{1354.5}{195}$	-	-	-	6.94

And all these values being substituted in the formula, will give

$$x = \sqrt{1121.40 + \frac{5113.584 + 20109.6 - 6667.92}{195} + 48.163 - 694} = 28.62 \text{ lines,}$$
 instead of  $28\frac{1}{2}$  before found.

#### Geometrical Application of the foregoing.

1398. Let the mean curve TKG of the arch (whatever its form) be traced as in *figs. 573, 574.*, the secant FO perpendicularly to the curve of the arch, and through the point K, where the secant cuts the mean curve, having drawn the horizontal line IKL, and raised from the point B a vertical line meeting the horizontal IKL in the point i, make Km equal to iK, and set the part mL from B to h, and then the double thickness of the arch from B to n. Let hn be divided into two equal parts at the point d, from which as a centre with a radius equal to half hn, describe the semi-circumference of a circle which will cut in E the horizontal line BA prolonged. The part BE will indicate the thickness to be given to the piers of the arches to enable them to resist the thrust.

1399. The truth of the method above given depends upon the graphic solution of the following problem: To find the side BE of a square which shall be equal to a given surface  $mL \times 2e$ ; an expression which is equivalent to  $2p$ , and we have already seen that  $x = \sqrt{2p}$  was a limit near enough; hence we may conclude that the thickness BE obtained by the geometrical method will be sufficiently near in all cases.

#### Experiments on surmounted Arches.

1400. The interior curve of *fig. 574.* is that of a semi-ellipsis 81 lines high; it is divided into four parts by an upright joint in the crown and two others towards the middle of the haunches determined by the secant FO, perpendicular to the interior part of the curve. Having traced the mean circumference GKT, the horizontal IKL, and the vertical Bi, we shall find

KL	-	-	-	-	36 $\frac{1}{2}$
IK	-	-	-	-	21 $\frac{1}{2}$
iK	-	-	-	-	17 $\frac{1}{2}$
IT	-	-	-	-	66 $\frac{1}{2}$
MK = d	-	-	-	-	19

The effect of the thrust indicated by  $KL - iK = mL$  will be

$19\frac{1}{2} \times 9$ , which gives for the expression  $p$  of the formula - 175.5

$2p$  therefore - 351.0

$d$  being  $66.5$ ,  $2pd$  will be  $351 \times 66.5$ , which gives - 23341.5

$m$ , which is  $KM \times AB$ , will be  $19 \times 9$ , which gives - 171.0

$c$ , that is,  $iK$ , being  $17\frac{1}{2}$  lines, we have  $2me = 171 \times 17\frac{1}{2} \times 2$ , which gives - 5899.50

The height of the piers  $a$  - 120.00

$b$ , which expresses the sum of the vertical efforts  $m + n$ , will be equal to  $MK + IT \times AB$  or  $19 + 66\frac{1}{2} \times 9$ , which gives - 769.50

Hence  $\frac{b}{a} = \frac{769.5}{120}$ , which gives - 6.41

And  $\frac{bb}{aa}$  gives - 41.11

Substituting these values in the formula,  $x = \sqrt{2p + \frac{2pd - 2mc}{a} + \frac{bb}{aa} - \frac{b}{a}}$

We have the equation  $x = \sqrt{351 + \frac{23341.5 - 5899.5}{120} + 41.11 - 6.41} = 16.77$

lines, or a little more than  $16\frac{3}{4}$  lines. The model of this arch would not however stand on piers less than 17 lines thick.

In taking the root of double the thrust the result is  $18\frac{3}{4}$  lines, as it is also by the geometrical method.

*Application to the Pointed Arch.*

1401. The model which *fig. 575.* represents was of the same height and width as the last, and the voussoirs were all of equal thickness. Having laid down all the lines on the figure as before, we shall find  $\frac{1}{2}K$  of the formula to be

$$x = \sqrt{2p + \frac{2pd - 2mc}{a} + \frac{bb}{aa} - \frac{b}{a}} \text{ wherein}$$

c	-	-	-	-	=	20
KL	-	-	-	-	=	34
mL	-	-	-	-	=	14
IT, represented by d,	-	-	-	-	=	63
MK	-	-	-	-	=	23
AB	-	-	-	-	=	9
mL $\times$ AB, represented by p in the formula, will be 14 $\times$ 9	-	-	-	-	=	126
and 2p	-	-	-	-	=	252
2pd will be 252 $\times$ 63, which gives	-	-	-	-	=	15876
m, which is KM $\times$ AB or 23 $\times$ 9,	-	-	-	-	=	207
2m = 414, 2mc = 414 $\times$ 20	-	-	-	-	=	8280

*Fig. 575.*

The height of the pier, represented by  $a$ , being 120, we have  $\frac{2pd - 2mc}{a} = \frac{15876 - 8280}{120} = 63.8$ ;  $b$ , or FT  $\times$  AB, will be  $86 \times 9 = 774$ ; whence  $\frac{b}{a} = \frac{774}{120} = 6.45$ , and  $\frac{bb}{aa} = 41.60$ . Substituting these values in the formula

$$x = \sqrt{252 + 63.8 + 41.6 - 6.45} = 12.46 \text{ lines for the thickness of the pier.}$$

In taking the square root of double the thrust the thickness comes out 15.88 lines, as it does by the geometrical method. Experiments showed that the least thickness of piers upon which the model would stand was 14 lines.

*Application to a surmounted Catenarean Arch.*

1402. The lines are all as in the preceding examples (*fig. 576.*). The whole arch acts on the pier in the direction FT, which is resolved into the two forces Tf and Tm, and the formula, as before, is

$$x = \sqrt{2p + \frac{bb}{aa} - \frac{b}{a}};$$

thus having found  $Bm = 22\frac{1}{2}$ , we have the value of  $p = 22\frac{1}{2} \times 9 = 201$ ; and  $2p = 402$ .

1403. This model was of the same dimensions as the preceding:  $b$ , which represents Tf  $\times$  AB, will be 769.5;  $\frac{bb}{aa}$  will be 6.41, and  $\frac{b}{a} = \frac{769.5}{120} = 6.41$ . These values substituted in the formula give

$$x = \sqrt{402 + 6.41 - 6.41} = 14.64 \text{ lines.}$$

1404. Experiment determined that the pier ought not to be less than 16 lines, and the geometrical method made it 20.05.

The following table shows the experiments on six different models.

*Fig. 576.*

Form of Arch.	Thickness of the Piers.		
	By the formula.	By experiment.	Geometrically.
	Lines.	Lines.	Lines.
The pointed -	12.46	14.00	15.88
The catenary -	14.64	15.00	20.05
The cycloid -	14.66	15.00	17.24
The parabolic -	15.85	16.50	21.50
The elliptic -	16.77	17.00	18.75
The cassinoid -	19.62	21.00	20.79

because, when once the parts are displaced, the force of the superior parts may lift up the lower parts without disturbing the abutments.

### Raking Arches.

1413. Let ACA' (*fig. 578.*) be the model of a raking arch of the same diameter and thickness as the preceding example, the voussoirs of equal thickness, and the piers of different heights, the lowest being 10 inches or 120 lines in height, and the other 14½ inches or 174 lines. The tangent at the summit is supposed parallel to the raking lines that connect the springing.

1414. This arch being composed of two different ones, the mean circumference on each must be traced, and each has its separate set of lines, as in the preceding examples; the horizontal line KL of the smaller arch is produced to meet the mean circumference of the other in S, and the interior line of its pier in g.

1415. The part KLS represents the horizontal force of the part of the arch KGS, common to the two semi-arches; so that if a joint be supposed at S, the part LK represents the effort acting against the lower part of the smaller arch, and LS that against the lower part of the larger arch. These parts resist the respective efforts as follows: the small arch with the force represented by iK, and the greater one with the force represented by gS. But as gS is greater than LS, transfer LS from g to f to obtain the difference fS, which will show how much LS must be increased to resist the effort of the larger half arch; that is, the effort of the smaller one should be equal to Lf; but as this last requires for sustaining itself that the larger one should act against it with an effort equal to KL, this will be the difference of the opposite effort, which causes the thrust against the lower part of the smaller arch and the pier from whence it springs. Hence, transferring fL from L to g, taking the half of iq and transferring it from L to h, the part hK multiplied by the thickness AB will be the expression for the thrust represented by p in the formula

FIG. 578.

$$x = \sqrt{2p + \frac{2pd - 2mc}{a} + \frac{bb}{aa} - \frac{b}{a}}.$$

Having found  $hK = 30\frac{1}{2}$  and  $AB = 9$ , we have for the value of  $p$   $30\frac{1}{2} \times 9 = 274\frac{1}{2}$ , and for that of  $2p - 549$ ,  $d$  which represents IT, being  $29\frac{1}{2}$ ,  $2pd = 16195\frac{1}{2}$ . In  $2mc$ ;  $m$ , which represents MK  $\times$  AB, will be  $12\frac{1}{2} \times 9 = 111$ , and  $2m = 222$ .

$c$ , which represents iK, being 8, we have  $2mc = 222 \times 8 = 1776$ .

The height of the pier represented by  $a$  being 174, we have

$$\frac{2pd - 2mc}{a} = \frac{16195\frac{1}{2} - 1776}{174} = 82.81$$

The vertical effort represented by  $b$ , or  $TF \times AB$ , will be  $41\frac{1}{2} \times 9 = 375$ ,

$$\text{and } \frac{b}{a} = \frac{375}{174} \text{ becomes } 2.15$$

$$\text{and } \frac{bb}{aa} = 4.64$$

Substituting these values in the formula, we have

$$x = \sqrt{549 + 82.81 + 4.64 - 2.16} = 23.08 \text{ for the thickness of the greater pier from which the smaller semi-arch springs.}$$

For the half of the greater arch, having produced the horizontal line IK'L', make K'r equal to VL', and bisect rL' in t; the line K't represents the effort of the smaller against the greater arch, which resists it with a force shown by i'K': thus making K'q equal to i'K, the effort of the thrust will be indicated by q't  $\times$  AB, whose value  $p$  in the formula will be

$$20 \times 9 = 180, \text{ and } 2p = 360$$

$$d, \text{ which is TI, being } 69\frac{3}{4}, 2pd \text{ will } = 25080$$

$$\text{In } 2mc, m \text{ being } 26 \times 9 = 234, \text{ and } c \text{ being } 23\frac{1}{2}, 2mc = 10842$$

$$a, \text{ the height of the smaller pier } = 120$$

$$\text{We have } \frac{2pd - 2mc}{a} = \frac{25080 - 10842}{120}, \text{ which becomes } = 118.65$$

$$b, \text{ which is } TF \times AB, \text{ will be } 95\frac{1}{2} \times 9 = 861$$

$$\frac{b}{a} = \frac{861}{120} = 7.175, \text{ and } \frac{bb}{aa} = 51.48$$

Substituting these values in the formula, we have

$$x = \sqrt{360 + 118.65 + 51.48 - 7.175} = 15.855 \text{ lines for the thickness of the smaller pier.}$$

Taking the square root of double the thrust, we should have for the larger pier 23.44 lines, and for the smaller one 19 lines. In the geometrical operation, for the larger pier make  $Bm$  equal to  $\frac{1}{2}K$  and  $Bn$  equal to  $2AB$ ; then upon  $un$  as a diameter describe a semicircle cutting the horizontal line  $BA$  produced in  $E$ .  $BE$  will be the thickness of the pier, and will be found to be 23.4 lines. For the smaller pier make  $B'm'$  equal to  $\frac{1}{2}t$  and  $B'n'$  equal to  $2A'B'$ . Then the semicircumference described upon  $un$  as a diameter will give 19 lines for the thickness.

1416. By the experiments on the model 22 lines was found to be the thickness necessary for the larger pier, and 18 lines for the smaller one.

### Arch with a level Extrados.

1417. The model of arch *fig. 579.* is of the same opening as the last, but with a level extrados, serving as the floor of an upper story. The thickness of the keystone is 9 lines. To find the place of fracture or of the greatest effort; having raised from the point  $B$  the vertical  $BF$  till it meets the line of the extrados, draw the secant  $FO$  cutting the interior circumference at the point  $K$ , and through this point draw the horizontal  $IKL$  and the vertical  $HKM$ .

The part  $CDKF$  will be that which causes the thrust, and its effort is represented by

$KL$ , which will be found	-	-	= 35.14
$FH = IK$ , which is $c$ in the formula, will be	-	-	= 18.86
The arch or circumference $KD$ of $10^\circ 36'$	-	-	= 38.28
The arch $KB$	-	-	= 46.57
The arch $DKB$	-	-	= 84.85
$KH$ , represented by $d$ ,	-	-	= 22
The vertical $HKM$	-	-	= 63
The height of the pier, represented by $a$ in the formula,	-	-	= 183

The area of the upper voussoir  $FKCD = 667.44$ ; but as the load of the haunches is borne by the inferior voussoir, we must subtract the triangle  $FKH = \frac{18.26 \times 22}{2} = 207.46$ . The remainder  $459.98$  multiplied by  $KL$  and divided by the arc  $KD$ , that is,  $\frac{459.98 \times 35.14}{38.28} = 422.24$ , represents the effort of the upper part.

1418. That of the lower part, represented by  $\frac{FBKH \times IK}{KB}$ , is  $\frac{651.07 \times 18.86}{46.57}$ , which becomes 263.67. The difference of the two efforts  $= 158.57$  will express the thrust or  $p$  of the formula, and we have  $2p = 317.14$ .

1419. The piers being supposed to be continued up to the line  $EC$  of the extrados will be greater than the arm of the lever of the thrust which acts at the point  $K$ . Thus the expression of the arm of the lever, instead of being  $a + d$ , as in the preceding examples, will be  $a - d$ , and the sign of  $\frac{2pd}{a}$  must be changed. In numbers,  $\frac{317.14 \times 22}{183} = 38.12$ ; therefore, in the formula,  $+\frac{2pd}{a}$  becomes  $-38.12$ .

1420. In the preceding examples,  $2mc$ , which represented double the vertical effort of the superior voussoir multiplied by the arm of its lever, becomes nothing, because it is comprised in the addition made to the lower voussoir; so that the formula now is

$$x = \sqrt{2p - \frac{2pd}{a} + \frac{bb}{aa} - \frac{b}{a}}.$$

$b$ , then, which always expresses the vertical effort of the half arch, is therefore

$$\frac{1111.05 \times 63}{84.85} = 824.94; \text{ and for } \frac{b}{a} \text{ we have } \frac{824.94}{183} = 4.5, \text{ and } \frac{bb}{aa} = 20.25.$$

Substituting these values in the last formula, we shall have

$$x = \sqrt{319.14 - 38.12 + 20.25 - 4.5} = 12.88 \text{ lines.}$$

Experiment gives 14 lines as the least thickness that can be relied on.

To find the thickness by the geometrical method, make  $Km$  equal to  $IK$  and  $Bm$  equal to  $mL$ ,  $Bn$  to double  $CD$ , and upon  $un$  as a diameter describe the semicircumference cutting the horizontal line  $OB$  produced in  $A$ : then  $BA = 17\frac{1}{2}$  lines is the thickness sought.

1421. Rondelet proves the preceding results by using the centres of gravity, and makes the result of the operation 12.74 instead of 12.80, as first found. But the difficulty of finding the centres of gravity of the different parts is troublesome; and with such a concurrence of results we do not think it necessary to enter into the detail of the operation.

Fig. 579.

*A different Application of the preceding Example.*

1422. The model (*fig. 580.*) is an arch similar to that of the preceding example, having a story above it formed by two walls, whose height is 100, and the whole covered by a timber roof. The object of the investigation is to ascertain what change may be made in the thickness of the piers which are strengthened in their resistance by the additional weight upon them.

1423. The simplest method of proceeding is to consider the upper walls as prolongations of the piers.

1424. In the model the walls were made of plaster, and their weight was thus reduced to  $\frac{3}{4}$  of what they would have been if of the stone used for the models hitherto described. The roof weighed 12 ounces. We shall therefore have that 100, which in stone would have represented the weight of the walls, from the difference in weight of the plaster, reduced to 75. In respect of the roof, which weighed 12 ounces, having found by experiment that it was equal to an area of 576 lines of the stone, both being reduced to equal thicknesses, we have 12 ounces, equal to an area of 13.82 whose half 6.91 must be added to that of the vertical efforts represented by  $b$  in  $\frac{b}{a}$  and  $\frac{bb}{aa}$ . Changing these terms into  $\frac{h}{a}$  and  $\frac{hh}{aa}$ , the formula becomes

$$x = \sqrt{2p - \frac{2pd}{a} + \frac{hh}{aa} - \frac{h}{a}}.$$

The height of the piers or  $a$  in the formula =  $183 + 75 = 258$ .

$p$  does not change its value, therefore  $2p$  (as in the preceding example) = 265.86.

$d$ , the difference between the height of the pier and the arm of the lever, will = 75.

$$\text{Hence, } \frac{2pd}{a} = \frac{565.85 \times 75}{258} = 77.28.$$

$$h, \text{ becomes } 750.69 + 691 = 1441.69.$$

$$\text{And } \frac{h}{a} = \frac{1441.69}{258} = 5.58.$$

$$\text{Again, } \frac{hh}{aa} = 31.22.$$

Substituting these values in the formula, we shall have

$$x = \sqrt{265.86 - 77.28 + 31.22 - 5.58} = 9.15.$$

In the model a thickness of 11 lines was found sufficient to resist the thrust, and taking the root of double the thrust the result is 13 lines.

1425. By the geometrical method, given in the last, taking from the result  $17\frac{1}{4}$  lines, there found, the value of  $\frac{h}{a}$ , that is, 5.58, the remainder  $11\frac{3}{4}$  lines is the thickness sought.

1426. It may be here observed, that in carrying up the walls above, if they are set back from the vertical BF in  $hf$ , the model required their thickness to be only 6 lines, because this species of false bearing, if indeed it can be so called, increases the resistance of the piers.

This was a practice constantly resorted to in Gothic architecture, as well as that of springing pointed arches from corbels, for the purpose of avoiding extra thickness in the walls or piers.

*Another Application of the Principles to a differently constructed Arch.*

1427. The model (*fig. 581.*) represents an arch of 11 voussoirs whereof 10 are with crossettes or elbows, which give them a bearing on the adjoining horizontal courses; the eleventh being the keystone. The opening is 9 inches or 108 lines, as in the preceding examples.

1428. Having drawn the lines BF, FC, the secant FO, and the horizontal line IKL, independent of the five courses above the line FC of the extrados, we have

Fig. 580.

Fig. 581.

$$\begin{aligned}
 \text{KL} &= 30.73 \\
 \text{IK} &= 23.27 \\
 \text{OC} = \text{BF} &= 78.00 \\
 \text{The arc KD} &= 32.70 \\
 \text{The arc KB} &= 52.15 \\
 \text{KG} &= 33.59
 \end{aligned}$$

$a$ , the height of the pier, = 198.00.

The area KFCL of the upper part of the arch will be 1223.10, from which subtracting that of the triangle FKG, which is 590.82, the remainder 832.28 being multiplied by 30.73 and divided by 32.7 makes the effort of this part 782.44.

1429. The area of the lower part is 697.95, to which adding the triangle FKG = 390.82, we have 1088.77, which multiplied by 23.27 and divided by 52.15, gives 485.82 for its effort. The expression of the thrust, represented by  $p$  in the formula,

$$\begin{aligned}
 x &= \sqrt{2p - \frac{2pd}{a} + \frac{bb}{aa} - \frac{b}{a}}, \text{ being equal to the difference of these two efforts,} \\
 &\text{will be } 296.62, \text{ and twice } p \quad \quad \quad = 593.24 \\
 &d, \text{ representing KG, being} \quad \quad \quad = 33.59 \\
 &\text{we have } 2pd = 19926.93, \text{ and } \frac{2pd}{a} \quad \quad \quad = 100.64
 \end{aligned}$$

$$\begin{aligned}
 b, \text{ representing the sum of the efforts of the semi-arch, will be } \frac{1921 \times 78}{85} &= 1762.03 \\
 \frac{b}{a} = \frac{1762.03}{198} &= 8.9 \text{ and } \frac{bb}{aa} \quad \quad \quad = 79.21
 \end{aligned}$$

Substituting these values in the formula, we have the equation

$$x = \sqrt{593.24 - 100.64 + 79.21 - 8.9} = 15.01.$$

By taking double the square root of the thrust the result is 23.91, a thickness evidently too great, because the sum of the vertical efforts, which are therein neglected, is considerable.

1430. The geometrical method gives 19 lines. The least thickness of the piers from actual experiment was 16 lines.

1431. Rondelet gives a proof of the method by means of the centres of gravity, as in some of the preceding examples, from which he obtains a result of only 13.26 for the thickness of the piers.

*Consideration of an Arch whose Voussoirs increase towards the Springing.*

1432. The model (*fig. 582.*) has an extrados of segmental form not concentric with its intrados, so that its thickness increases from the crown to the springing. The opening is the same as before, namely, 9 inches, or 108 lines. The thickness at the vertex is 4 lines, towards the middle of the haunches  $7\frac{1}{2}$  lines, and at the springing  $14\frac{1}{2}$  lines. The centre of the line of the extrados is one sixth part of the chord AO below the centre of the intrados; so that

$$\begin{aligned}
 \text{The radius DN} &= 68.05 \\
 \text{KL} &= 38.18 \\
 \text{IK} &= 15.82 \\
 \text{The arc BK} &= \text{KC} = 42.43
 \end{aligned}$$

1433. The area KHDC of the upper part of the arch is 258.75, that of the lower part BAHK 486.5; hence the effort of the upper part is represented by the expression  $\frac{258.75 \times 38.18}{42.43} = 232.47$ .

1434. The half segment ABe being supposed to be united to the pier; BeHK, whose area is 178, is the only part that can balance the upper effort; its expression will be  $\frac{178 \times 15.82}{42.43} = 66.24$ . The difference of the two efforts 166.23 will be the expression of the thrust represented by  $p$  in the formula

Fig. 582.

$$x = \sqrt{2p + \frac{2pd - 2mc}{a} + \frac{bb}{aa} - \frac{b}{a}}$$

$$\begin{aligned}
 \text{Thus } 2p \quad \quad \quad &= 332.46 \\
 \text{IB} = \text{KL, indicated by } d, \quad \quad \quad &= 38.18 \\
 \text{Which makes the value of } 2pd \quad \quad \quad &= 12693.92 \\
 \text{The vertical effort of the upper part indicated by } m = \frac{258.75 \times 15.82}{42.43} &= 96.30 \\
 \text{and for } 2pm \quad \quad \quad &= 192.60 \\
 \text{The value of } c \text{ being } 15.82, \text{ we have } 2mc \quad \quad \quad &= 3046.50
 \end{aligned}$$

The height of the piers being still 120, we have

$$\frac{2pd - 2mc}{a} = \frac{12693.92 - 3046.5}{120} = 80.39$$

$b$ , which indicates the vertical effort of the half arch repre-

$$\begin{aligned} \text{sented by FB, will be } & \frac{745.26 \times 54}{84.85} = 473.48 \\ \frac{b}{a} = \frac{473.48}{120} & = 3.95 \\ \text{and } \frac{bb}{aa} & = 15.56 \end{aligned}$$

These values being substituted in the formula, will give

$$x = \sqrt{332.46 + 80.39 + 15.56} - 3.95 = 16.74 \text{ lines.}$$

1435. The smallest thickness of pier that would support the arch in the model was  $17\frac{1}{2}$  lines.

1436. With the geometrical method, instead of the double of CD, make B*h* double the mean thickness HK, and B*n* equal to *mL*, and on *nh* as a diameter describe the semicircumference cutting OB produced in E; then EB =  $18\frac{1}{2}$  lines will be the thickness sought.

1437. If the pier is continued up to the point *e* where the thickness of the arch is disengaged from the pier, the height of the pier represented in the formula by *a* will be 151.5 instead of 120, and the difference *b*, instead of being  $\frac{745.26 \times 54}{85}$ , will be only  $\frac{436.75 \times 54}{85} = 277.46$ .

1438. *d*, expressed by *Ie*, will be 6.5, all the other values remaining the same as in the preceding article, the equation is

$$x = \sqrt{332.46 - 5.71 + 4} - 2 = 16.21.$$

1439. Using the method by means of the centres of gravity, Rondelet found the result for the thickness of the piers to be 15.84. So that there is no great variation in the different results.

1440. In the preceding examples arches have been considered rather as arcades standing on piers than as vaults supported by walls of a certain length. We are now about to consider them in this last respect, and as serving to cover the space enclosed by the walls.

In respect of cylindrical arches supported by parallel walls, it is manifest that the resistance they present has no relation to their length; for if we suppose the length of the vault divided into an infinite number of pieces, as C, D, E, &c. (*fig. 584. No. 2.*), we shall find for each of these pieces the same thickness of pier, so that all the piers together would form a wall of the same thickness. For this reason the surfaces only of the arches and piers have been hitherto considered, that is, as profiles or sections of an arch of any given length. Consequently it may be said that the thickness of wall found for the profile in the section of an arch would serve for the arch continued in length infinitely, supposing such walls isolated and not terminated or rather filled by other walls at their ends. When cylindrical walls are terminated by walls at their extremities, after the manner of gable ends, it is not difficult to imagine that the less distant these walls are the more they add stability to those of the arch. In this case may be applied a rule which we shall hereafter mention more at length under the following section on Walls.

1441. If in any of the examples (*fig. 582. for instance*) PR be produced indefinitely to the right, and from R on the line so produced the length of the wall supporting the arch be set out, and if from the extremity of such line another be drawn, as TB produced through B, indefinitely towards *a*, and B*a* be made equal to the thickness of the pier first found, a vertical line let fall from *a* will determine the thickness sought. When arches are connected with these cross walls, the effect of the thrust may be much diminished if they are not very distant. If there be any openings in the walls, double the length of them must be added to that of the wall as well as of any that may be introduced in the gable wall.

1442. *Fig. 583.* represents the mode in which an arch fails when the piers are not of sufficient strength to resist the thrust: they open on the lower part of the summit at DM and on the upper part of the haunches at HN; from which we may infer that the thrust of an arch may be destroyed by cramping the under side of the voussoirs near the summit and the upper side of those towards the middle of the haunches; and this method is greatly preferable to chains or iron bars on the extrados, because these have no effect in preventing a failure on the underside. Chains at the springing will not prevent failure in arches whose voussoirs are of equal depth but that too small, inasmuch as there is no counteraction from them against the bulging

Fig. 583

height of the pier being  $a$ , its cube will be  $\frac{ax^3}{2}$ . The arm of the lever of this pier will be determined by the distance of the vertical let fall from its centre of gravity on the line  $HF = \frac{x}{3}$ , which gives for the pier's resistance  $\frac{ax^2x}{6}$ .

1451. This resistance will be increased by the vertical effort of each part of the vault multiplied by the arm of its lever.

That of the upper part will be expressed by its cube multiplied by the vertical KM, and the product divided by the mean arc KG.

The cube of this part will be equal to the mean area; that is, the arc KG multiplied by the thickness of the vault.

1452. To obtain the mean area, multiply KG less KM by the length GO taken on the plan. The length of the arc KG being 46 and KM  $17\frac{1}{4}$ , we shall have  $KG - KM = 28\frac{3}{4}$ ; GO being 54, the mean area will be  $28\frac{3}{4} \times 54 = 1558$ . This area multiplied by 9, the thickness of the vault, makes the cube of the upper part  $14024\frac{1}{2}$ , which multiplied by  $KM = 17\frac{1}{4}$  and divided by the arc  $KG = 46$ , makes  $5226\frac{1}{2}$  the value of the vertical effort of the part of the arch  $m$  in the formula; and the arm of its lever is  $IK + iH$ .

1453.  $IK$  being  $c$  and  $iH = x$ , its expression will be  $mx + mc$ .

The vertical effort of the lower part will be represented by its cube multiplied by TI, and the product divided by the length of the arc TK.

This cube will be found by multiplying the mean area by the thickness of the vault. The area being equal to the arc  $TK - TI \times GO$ , that is,  $46 - 41\frac{5}{11} \times 54 = 250\frac{2}{11}$  for the mean area and  $250\frac{2}{11} \times 9 = 2256\frac{2}{11}$  for the cube of the lower part of the vault. This cube multiplied by TI and divided by the arc TK gives  $\frac{2256\frac{2}{11} \times 41\frac{5}{11}}{6} = 2028\frac{3}{11}$  for the value of the vertical effort of the part  $n$  of the formula. And it is to be observed, that this effort acting against the point B, the arm BF of the lever will be  $x$  and its expression  $nx$ .

1454. Bringing together all these algebraic values we obtain the equation  $pa + pd = \frac{ax^3}{6} + mx + mc + nx$ ; and making  $m + n$ , which multiplies  $x = b$ , we have  $pa + pd = \frac{ax^3}{6} + bx + mc$ . Transferring  $mc$  to the other side of the equation, we have  $pa + pd - mc = \frac{ax^3}{6} + bx$ . Lastly, multiplying all the terms of the equation by  $\frac{6}{a}$  for the purpose of eliminating  $x^3$ , we shall have instead of the preceding formula  $6p + \frac{6pd - 6mc}{a} = x^3 + \frac{6bx}{a}$ , which is an equation of the third degree, whose second term is wanting. For more easily resolving this equation, let us find the value of  $6p + \frac{6pd - 6mc}{a}$  and that of  $\frac{6b}{a}$ , by which  $x$  is multiplied in the second part of the equation.

$p$ being $11683\frac{3}{4}$ , $6p$ will be	-	-	-	=	$70069\frac{3}{4}$
$d$ being $41\frac{5}{11}$ , $6pd$ will be	-	-	-	=	$2899124\frac{3}{11}$
$m$ being $5226\frac{1}{2}$ , $6mc$	-	-	-	=	$537593\frac{1}{2}$

Thus  $\frac{6pd - 6mc}{a} = \frac{2361537\frac{3}{11}}{120} = 19679\frac{5}{12}$ , and  $6p + \frac{6pd - 6mc}{a} = 89779\frac{1}{12}$ , which we will call  $g$ , for the purpose of simplifying the remainder of the calculation.

$b$ , which represents  $m + n$ , will be  $5226\frac{1}{2} + 2038\frac{3}{11} = 7255\frac{2}{11}$ , and  $\frac{6b}{a} = \frac{43534}{120} = 362\frac{2}{15}$ ; this we will call  $f$ ; so that instead of the equation  $6p + \frac{6pd - 6mc}{a} = x^3 + \frac{6bx}{a}$ , we have  $g = x^3 + fx$ , which is thus to be resolved (Bossut, *Elemens d'Algebra*):—

$$x = \sqrt[3]{\frac{g}{2}} + \sqrt[3]{\frac{fg}{4} + \frac{f^3}{27}} + \sqrt[3]{\frac{g}{2}} - \sqrt[3]{\frac{fg}{4} + \frac{f^3}{27}}.$$

Substituting in this formula the values of  $g$  and  $f$ , we have

$$x = \sqrt[3]{448894} + \sqrt[3]{2015073623 + 1767902} + \sqrt[3]{448894} - \sqrt[3]{2015073623 + 1767902} \\ = \sqrt[3]{448894} + 44909\frac{1}{4} + \sqrt[3]{448894} - 44909\frac{1}{4}, \text{ from which extracting the cube roots, we have } \\ x = 44\frac{3}{4} - 2\frac{3}{4} = 42 \text{ for the length BF of one of the sides of the triangular pier BAF; the other FA may be determined by the production of the diagonal or line of groin OB.}$$

The part of the pier answering to the part of the vault BNO is determined by drawing from the points B and A the parallels BM and MA to FA and FB. These two triangles will form a square base, each of whose sides will be 42 lines, answering to one quarter of the vault KBNO; thus, to resist the thrust of the vault, four piers, each 42 lines thick, are necessary.

1455. The above result corresponds in a singular manner with the experiments which were made by Rondelet, from which he deduced a thickness of  $43\frac{1}{2}$  lines. In his investigation of the example by means of the centres of gravity  $40\text{--}53$  lines was the result. Our limits prevent further consideration by other examples: we will merely therefore observe, that

the method above given seems to be a safe guide to the architect. In the case of oblong arches, the results must be obtained for each side.

1456. In the case of groinings composed of many bays, the chief care necessary is in the external piers, which will require especially to be of sufficient thickness. Those in the middle, being counterbalanced all round, have only to bear the weights of their respective arches, for which purpose they must have a proportional area and be of such stone as the weight will not crush. But it ought to be recollected that in good construction the area of the points of support should be so distributed as to establish for each a sufficient strength, because a single weak point will often endanger the whole fabric.

1457. In practice, a readier method will be wanting than that which has been just discussed; we therefore subjoin one which agrees well enough with theory and experiment, and it is as follows. Let ABCD (*fig. 585. No. 1.*) be the space to be covered by a

Fig. 585.

groined vault supported in the centre by the pier E. Dividing each side into two equal parts, draw the lines HI, FG crossing each other in the centre E', and the diagonals AE, EB, EC, ED and HF, HG, IF, IG crossing each other in the points K, K', K'', K'''. In No. 2, draw the pier its half height to the level of the springing, which half height transfer from E to L, and divide EL into twelve parts. One of these parts will be a half diagonal of the pier. For the intermediate piers H, F, I, G, after finding the diagonals of the half piers, produce them outwards to double their projection within, so that altogether their thickness may be once and a half their width. For the angular piers this method will give an area of base  $1\frac{1}{2}$  times greater, which will enable them to resist the thrust they have to sustain.

1458. When the width of the space to be vaulted is to be divided into three bays, and that of the middle is required to be raised above those of the other two, as in the case of churches with side aisles, the bases of the points of support may be determined in two ways. That most used, which is borrowed from the Gothic examples, is to give to the areas of the bases of the points of support merely the extent necessary to bear the load they

are to receive, by throwing the strain of the thrust upon the external piers by means of flying buttresses, and giving to their points of support a position and surface of base capable of effectual resistance.

1459. The most simple method derived from the principles of the theory for the first case is as follows : —

Having laid down the plan of the two bays which fall upon the same pier (*fig. 586. No. 1.*), take one half of the sum of the two semi-diagonals AD, AE, to which add one

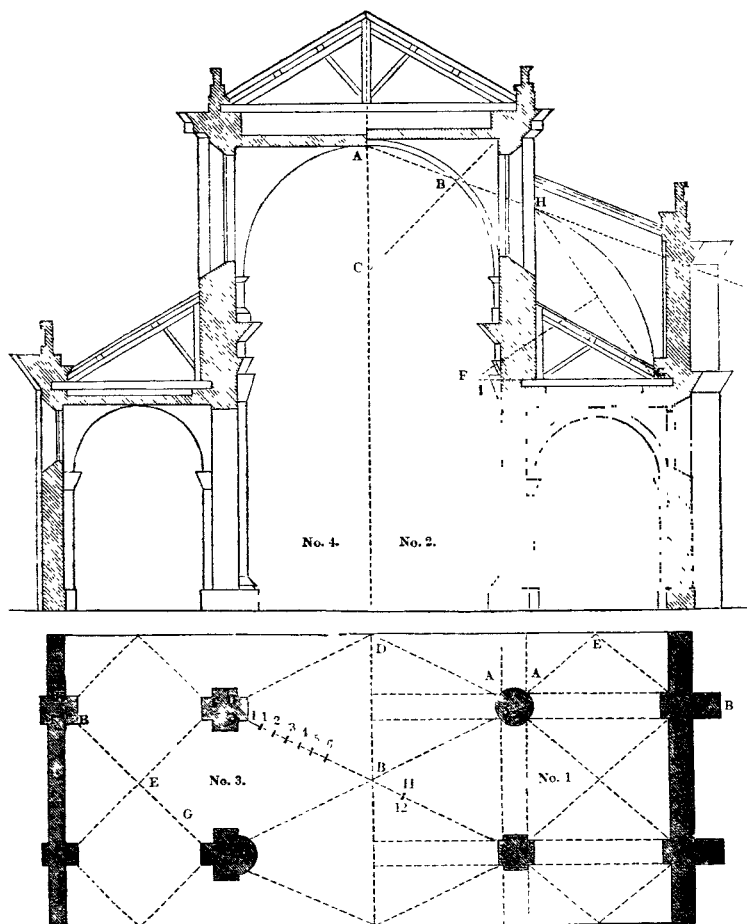

Fig. 605.

half of the height of the point of support, and taking a twelfth part of the whole as a radius, describe a circle, and it will indicate the surface sought of the base of the point of support. If it be not circular it must be circumscribed with the form that may be required, so as rather to increase than diminish its solidity. For the exterior point of support B let a rectangle be formed, having for its width the side of a square inscribed in the preceding circle, and in length double.

1460. Above the roofs of the sides a flying buttress may be carried up, whose pier may be raised on that below, set back one sixth from the exterior face and sloped as much on the interior. The line of summit or tangent of this flying buttress, which should be of the single arc of a circle, will be determined by the chord of the arc of the upper part of the vault produced indefinitely. To find the centre, draw the chord GH (No. 2.), on the middle of which raise a perpendicular, which will cut the horizontal line GF in the point I, which will be the centre of the arc. These raking arches may be connected by

other return arches, which may bear a floor above with a support, upon which a passage round the building may be made, and this may be concealed by an attic order outside.

1461. In the second case, the base of a pier must be found capable of resisting the effort of the great middle vault of the nave, by taking as the height of its pier the distance from its springing from the upper side of the side vaults No. 3., and laying the half of this height from B to H on the plan No. 2. Then having divided IH into twelve equal parts, make IA equal to one of them and AF equal to two. The rectangle made upon the diagonal FI shows the area of the interior pier, to which are to be added, to the right and left, projections to receive the arches of the sides. The length FD is to be divided into six equal parts, whereof two are for the projection of the pilaster or interior half column, upon which the entablature is profiled, three for the thickness of the wall, and one for the pilaster on the side aisles, whose prolongation will form a counterfort above the lower sides.

1462. For the external pier B, as before, one half the height to the springing must be transferred from EG, and  $\frac{1}{3}$  of BG from B to L; lastly,  $\frac{2}{3}$  from B to K: the rectangle formed upon the diagonal KL is equal to the area of the pier. We must add, as for that in front, the projections to receive the arches or windows, as shown in No. 2.

1463. As long as the intervals between the piers are filled in with a wall, if that be placed flush with the outside, the piers will form pilasters inwards (see fig. 585.), as *ahef*, whose projection *ef* is equal to one half of the face *he*; this wall ought to have a thickness equal to *he*; but if it is brought to the inner line of the face of the piers they need be only two thirds of the thickness; so that the piers will form counterforts on the exterior. In conclusion, knowing the effort of the thrust, the calculations will not be attended with difficulty in providing against it by adequate means of resistance.

#### ON THE MODEL OF A COVED VAULT.

1464. The model (fig. 587. Nos. 1. and 2.) is square on the plan, each of its sides is 9 inches internal measure, enclosed by a wall 10 inches high to the springing of the vault. The vault is semicircular in form, the voussoirs throughout 9 lines thick, and it is composed of seventeen parts above the line of greatest effort (see 1391.), as shown in Nos. 1. and 2. in the plan and section. On one of the sides of the first is supposed to be traced the mean circumference TKG, the tangents FT, FG, the secant FO, the horizontal line IKL, and the verticals Bi and MK. We may now therefore consider this vault as four triangular pieces of cylindrical arches, each resting throughout the length of their base on one of the walls which forms the sides of the square. As the portions of arches or vaults are equal, it is only necessary to take one of them for an example.

1465. In the last example, cubes are taken instead of the surfaces, and surfaces instead of lines. Thus expressing the length of the wall by *f*, its height by *a*, and its thickness by *x*; the arm of the lever being always  $\frac{x}{2}$ , its resistance is expressed by  $afx \frac{x}{2}$ .

Fig. 587.

Making the thrust	-	-	-	=p
EH=TI=KL=KV	-	-	-	=d
PH	-	-	-	=a+d
The sum of the vertical efforts of the upper part	-	-	-	=m
That of the lower parts	-	-	-	=n
The part IK of the horizontal line	-	-	-	=c
TB=half the thickness of the arch	-	-	-	=e
The arm of the lever will be	-	-	-	=c+x
TE	-	-	-	=x-e,

The equation is  $pa + pd = \frac{afx^2}{2} + (m+n)x - ne + mc$ ;

and making  $m+n=b$ ,

$$\frac{afx^2}{2} + bx = pa + pa + ne - mc;$$

$$\text{Whence } x = \sqrt{\frac{2p}{f} + \frac{2pd + 2mc - 2mc}{af} + \frac{b^2}{a^2f^2}} - \frac{b}{af}$$

1466. If, however, we suppose the effort to take place at the point B, a supposition hitherto made in the formulæ, we have  $e=0$ , and the value of  $x$  becomes

$$x = \sqrt{\frac{2p}{f} + \frac{2pd - 2mc}{af} + \frac{b^2}{a^2f^2}} - \frac{b}{af}$$

1467. The horizontal effort of the upper part, represented by the line KL, will be expressed by the triangle  $eEd$  of the plan; that of the lower part  $iK$  in the section will be expressed by the trapezium  $eBCd$  on the plan.

1468. The plan of the vault being square, the base  $ed$  will be double  $Eg = KL$  of the section; and the area of the triangle  $eEd$  equal to the square of  $KL = 41\frac{5}{11} \times 41\frac{5}{11} = 1710\frac{1}{4}$ .

1469.  $Ea$  of the plan being equal to the square of 54 less the square of  $41\frac{5}{11}$ , that is,  $1206\frac{3}{4}$ , the superior effort being  $1710\frac{1}{4}$ , their difference is 504, which being multiplied by the thickness of the vault, or 9, is 4536 for the expression of the thrust represented by  $p$  in the formula, and for that of

$$2p = 9072 \text{ and } \frac{2p}{f} = 84,$$

$d$ , which represents TI, being  $41\frac{5}{11}$ ,  $2pd = 375192$ .

1470. To obtain the vertical effort of the upper part of the arch represented by  $m$ , its cube must be multiplied by KM, and the product divided by the arc KG.

1471. The cube of this part is equal to the curved surface passing through the middle of its thickness multiplied by the thickness. The mean area is equal to the product of the length  $nq$  taken on the plan multiplied by KM.

$nq$  being 117, and KM 17, the product expressing such mean area is  $2005\frac{1}{2}$ , which multiplied by 9 makes the cube  $18051\frac{1}{4}$ . This cube again multiplied by  $KM = 17\frac{1}{2}$ , and divided by the length of arc  $KG = 46$ , gives 6727 for the value of  $m$ , and for  $2m$  13454;  $c$  being  $12\frac{9}{11}$ ,  $2mc = 170100\frac{3}{11}$ .

$$\frac{2pd - 2mc}{af} = \frac{375192 - 170100\frac{3}{11}}{120 \times 108} = 15.82.$$

$b$ , representing the vertical effort of the half vault, will be expressed by the cube multiplied by  $Bf = 58\frac{1}{2}$ , and divided by the mean circumference  $TKG = 92$ .

1472. To obtain the cube, the mean superficies, that is,  $nq \times Bf$  or  $117 \times 58\frac{1}{2}$ , is to be multiplied by the thickness  $AB = 9$ , which gives  $6844\frac{1}{2} \times 9 = 61600\frac{1}{2}$ .

This cube multiplied by  $Bf = 58\frac{1}{2}$  and divided by the mean circumference  $TKG = 92$ , that is,  $61600\frac{1}{2} \times \frac{58\frac{1}{2}}{92} = 39169.88$ , for the value of  $b$ , and for that of  $\frac{b}{a}$ ,  $\frac{39169.88}{120 \times 108} = 3.02$  and  $\frac{bb}{aa} = 9.12$ . Substituting these values in the formula,

$$x = \sqrt{\left(\frac{2p}{f} + \frac{2pd - 2mc}{af} + \frac{bb}{a^2f^2}\right)} - \frac{b}{af}.$$

$$\text{Hence } x = \sqrt{84 + 15.82 + 9.12} - 3.02 = 7.41;$$

that is, a little less than  $7\frac{1}{2}$  lines for the thickness of the walls, which is less than that of the vault; and shows that by giving the walls the same thickness as the vault, all the requisite solidity will be obtained. This is proved by experiments, for in the model the vault was borne equally well on walls of 9 lines in thickness divided into 8 parts, as upon 12 Doric columns whose diameter was 9 lines, four being placed at the angles and eight others under the lower part of the vault.

1473. To find the thickness of these walls by the geometrical method: Take the difference between the area of the triangle  $BEC$  and that of the triangle  $Eed$ , which divide by the length  $BC$ .

Thus, the area of the greater triangle being  $\frac{108 \times 54}{2} = 2916$ ; that of the smaller one,  $\frac{82\frac{5}{11} \times 41\frac{5}{11}}{2} = 1710.4$ ; their difference,  $1205.6$  divided by  $108 = 11.16$ , which transfer to the profile from  $B$  to  $h$ , and make  $Bn$  equal to the thickness of the vault. Upon  $nh$ , as a diameter, describe a semicircle, which at its intersection with the horizontal line  $BE$  will determine the thickness of the vault, and be found to be 10 lines.

1474. The small thrust of this species of vaulting occurs on account of the upper part, which causes it, diminishing in volume in proportion as the horizontal effort becomes more considerable, and because the triangular form of its parts and their position give it the advantage of having the larger sides for bases; whilst, in groined vaulting, the triangular parts resting only on an angle, the weight increases as the horizontal efforts.

1475. Moreover, as the return sides mutually sustain each other, a half vault, or even a quarter vault, on a square base, would stand if the walls were 10 lines thick, proving that

the opposite parts, acting little more than against each other, the thrust becomes almost nothing.

1476. By the method of the centres of gravity, Rondelet found a result less than that above given; but that arose from neglecting some points in the calculation which it was difficult to introduce for general practice.

1477. It is obvious that in the above application great allowance must be made when the apartment to be vaulted is not square; that is, its advantages diminish as the two opposite sides become longer than the width, and when the length is twice the width, or even much less, the thrusts must be calculated on the principle of cylindrical vaulting; and as in this species of vaulting the greatest effort occurs in or towards the middle of the sides, opening for doors and windows should there be avoided.

*Application of the Method to Spherical Vaulting.*

1478. The models (*fig. 588. Nos. 1. and 2. and fig. 589. Nos. 1. and 2.*) were of the

same opening as the last mentioned. They are cut into eight equal parts by vertical planes crossing each other in the axis; each of these parts is subdivided by a joint at 45 degrees, altogether forming sixteen pieces. The vault stands on a circular wall of the same thickness divided into eight parts corresponding to those of the vault. All the parts are so arranged as to form continued joints without any bond, in order to give the experiment the most disadvantageous result. Yet it stood firmly, and was even capable of bearing a weight on the top.

1479. If for these eight pieces of circular wall we substitute eight columns of equal height, as in No. 1. *fig. 589.*, so that the vertical joints fall over the middle of each column; the vault will still stand, although the cube of these columns, as well as their weight, occupies only one ninth part of the circular wall for which they are substituted.

From this it is evident that spherical vaults have less thrusts than coved vaults.

1480. Applying the method of the preceding examples, describe the mean circumference (*fig. 588. Nos. 1. and 2.*), draw the tangents TF, GF, the secant FO, the horizontal line IKL, and the verticals KM and Bi; lastly, calculating for one eighth of the vault, take the sector Ohm to express the horizontal effort indicated by KL, and the part HhMm to express the horizontal effort of the lower part.

1481. The difference of these areas multiplied by the thickness of the vault will be the expression of the thrust  $p$  of the formula.

1482. The radius Om of the sector being  $41\frac{5}{11}$  and its length  $32\frac{1}{2}$ , its area will be  $672\frac{3}{36}$ .

1483. The area of hHMm will be equal to the difference of the two sectors OHM and Ohm, whereof the first is equal to the product of half OM = 27 by the arc HM =  $42\frac{1}{2}$ , or 1145 $\frac{1}{2}$ , the second =  $672\frac{3}{36}$ ; whence the difference =  $473\frac{3}{36}$ .

1484. The thrust, being equal to the difference between  $672\frac{3}{36}$  and  $473\frac{3}{36}$ , will be  $198\frac{15}{36} \times 9$ ; therefore  $p = 786\frac{23}{36}$ .

1485.  $f$ , representing the developement of one eighth part of the circular wall, will be  $42\frac{1}{2}$ , whence  $\frac{p}{f}=42$ .  $d$ , the difference between the arm of the lever and the height of the pier, being  $41\frac{5}{16}$ , we shall have  $pd=73897\frac{1}{4}$ .

1486. To obtain the value of  $mc$  we must first find that of  $m$ , which represents the vertical effort of the upper part of the vault, and is equal to the cube of this part multiplied by  $KM$  and divided by the arc  $KG$ . This cube is equal to the difference of the cube of the sector of a sphere in which it is comprised with that which forms its interior capacity. We will merely recall here to the reader's recollection from a previous page, that the cube of the sector of a sphere is equal to the product of the superficies of the sphere whereof it forms a part by one third of the radius, and that this superficies is equal to the product of the circumference of a great circle by the line which measures its depth. Thus the area of the great sector  $ORCr$  (*fig.* 588. No. 1.) is equal to the product of the great circle, whereof  $Aa$  is the diameter  $=126$ , by  $CS=18\frac{5}{16}$ , which is  $7308$ , and its cube  $7308 \times 21 = 153468$ .

1487. The area of the small sector  $ONDn$  will be equal to the product of the great circle, whereof  $Bb$  is the diameter  $=108$  by  $VD=15\frac{3}{8}$ , which gives  $5369\frac{3}{8}$ , and its cube by  $5369\frac{3}{8} \times 18 = 96648\frac{3}{8}$ . Deducting this last cube from that of the great sector already found  $=153468$ , the remainder  $56819$  will be the cube of the upper part of the vault forming the cap, whose eighth part  $7102\frac{3}{8}$  will be the cube sought, which multiplied by  $KM=17\frac{1}{2}$  and divided by the arc  $KG=46$ , gives  $2646\frac{3}{8}$  for the value of  $m$  in the formula;  $c$ , which represents  $iK$ , being  $12\frac{9}{16}$ , we have

$$mc = 33461\frac{3}{8}; \quad pd - mc \text{ will be } 73897\frac{1}{4} - 33461\frac{3}{8} = 40436\frac{1}{8};$$

$$\text{and for } \frac{pd - mc}{af}, \quad \frac{40436\frac{1}{8}}{120 \times 42\frac{1}{2}} = 7.92.$$

1488. In the preceding application to the model of the coved vault, the walls being straight, the distance of their centre of gravity from the point of support was equal to half their thickness; in this, the wall being circular, its centre of gravity is so much more distant from the point of support as it takes in more or less a greater part of the circumference of the circle. By taking it only the eighth part, the centre of gravity falls without the thickness of the walls, by a quantity which we shall call  $e$ , so that the arm of the lever, instead of being  $\frac{x}{2}$ , will be  $e + x$ , which changes the preceding formula to

$$afx(e + x) + bx = pa + pd - mc;$$

arranging with reference to  $x$ , this becomes

$$afx^2 + (eaf + b)x = pa + pd - mc;$$

whence we obtain  $x^2 + (e + \frac{b}{af})x = \frac{pa + pd - mc}{af}$ , and making  $e + \frac{af}{b} = 2h$ , we shall have

$$x = \sqrt{\frac{p}{f} + \frac{pd - mc}{af}} + h^2 - h.$$

$b$  expresses the vertical effort of an eighth part of the vault equal to its cube, multiplied by the vertical  $Bf$ , and divided by the mean circumference  $TKG$ . This cube is equal to an eighth of the sphere, whereof  $Aa$  is the diameter, less that of the eighth part of a sphere whose diameter is  $Bb$ .

1489. The diameter  $Aa$  being  $126$ , the eighth of the circumference of a great circle will be  $49\frac{1}{2}$ , which, multiplied by the vertical axis, which in this case is equal to the radius or  $63$ , gives for the area of one eighth part of the sphere  $3118\frac{1}{2}$ , and for its cube  $3118\frac{1}{2} \times 21 = 65688\frac{1}{2}$ .

1490. The diameter  $Bb$  being  $108$ , an eighth part of the circumference of the great circle will be  $42\frac{1}{2}$ , which, multiplied by the radius  $54$ , gives for the area  $2291\frac{1}{2}$ , and for its cube  $2291\frac{1}{2} \times 18 = 41240\frac{1}{2}$ ; taking the smaller of these cubes from the greater, the difference  $24447\frac{1}{2}$  will be that of this eighth part of the vault, which must be multiplied by  $Bf = 58\frac{1}{2}$ , and the product  $1430203\frac{1}{8}$ , divided by the mean arc  $TKG = 91\frac{1}{2}$ ; the quotient  $15558$  expresses the vertical effort of the eighth part of the vault, represented by  $b$  in the formula, whence  $\frac{b}{af} = \frac{15558}{5100} = 3.05$ .

$e$  being  $2.51$ , we shall have for the value of  $h$   $2.78$  and  $h^2 = 7.72$ .

Substituting the values thus found in the formula

$$x = \sqrt{\frac{p}{f} + \frac{pd - mc}{af}} + h^2 - h,$$

$$\text{we have } x = \sqrt{42 + 7.92 + 7.72} - 2.78 = \sqrt{57.64} - 2.78 = 4.72.$$

By using the method of the centres of gravity, Rondelet found the result rather less than that just found.

1491. The result of all these calculations induces the following facts: — I. That for a

semicircular cylindrical vault, whose length is equal to its diameter, the area of the two parallel walls is 4698. II. That that of the four square piers supporting a groined arch is 7056. III. That of the four walls of the coved vault, the area should be 3425 $\frac{1}{2}$ . IV. That that of the spherical vault is 1238 $\frac{1}{2}$ .

1492. In respect of the opening of these vaults, which is the same for all the examples, taking the area of the circular wall for the spherical vault at 1,

That of the walls of the coved vault will be a little less than 3.	
That of the cylindrical vault	- - less than 4.
That of the groined arch	- - less than 6.

But if we look to the space that each of these vaults occupies in respect of walls and points of support, we shall find that in equal areas the walls of the cylindrical vault will be  $\frac{2}{3}$  of such space.

Those of the coved vaulting less than	- - $\frac{1}{3}$ of such space.
The piers of the groined arch a little more than	- $\frac{1}{2}$ —
The circular wall for spherical vault a little more than	$\frac{1}{2}$ —

So that, if we suppose the space occupied by each of these vaults to be 400,

The walls of the cylindrical vaulting will be	115
Those for the coved vault	- - 91
The piers for the groined arch	- - 60
The circular wall for the spherical vault	- 48

Which figures therefore show the relative proportions of the points of support necessary in each case.

1493. It is a remarkable circumstance that by the formula the coved and spherical vaults give to the walls a less thickness than that of the arch. But although experiment has verified the formula, we cannot be supposed to recommend that they should be made of less thickness in practice; but we see that, if of the same thickness, considerable openings may be used in them. Irregular as well as regular compound vaults being only an assemblage of the parts of more simple ones, if what has already been said be well understood, and the examples given have been worked out by the student, he will not be much at a loss in determining the efforts of all sorts of vaults.

*On the adhesive Power of Mortar and Plaster upon Stones and Bricks.*

1494. The power of mortar and plaster will of course be in proportion to the surface of the joints, compared with the masses of stone, brick, or rubble. Thus a voussoir of wrought stone, one foot cube, may be connected with the adjoining voussoirs by four joints, each of 1 foot area, in all 4 feet. But if instead of this voussoir three pieces of rough stone or rubble be substituted instead of 4 feet area of joints, we shall have 8. Lastly, if bricks be employed instead of rubble, we shall want 27 to form the same mass, which gives for the development of the joints 13 feet. Thus, representing the force which connects the voussoirs in wrought stone by 4, that representing the joints of the rough stones will be 8, and that for bricks 13: whence we may infer that arches built with rough stones will have less thrust than those in wrought stone, and those in bricks more than three times less. From experiments made by Rondelet, he found that at the end of six months some species of mortar showed a capability of uniting bricks with sufficient force to overcome the efforts of thrust in a vault segmental to  $\frac{3}{4}$  of a semicircle, 15 feet diameter and 4 inches thick, the extrados being 4 inches concentrically above the intrados. Plaster united a vaulted arch of 18 feet opening, of the same form and thickness. This force is, moreover, greater in arches whose voussoirs increase from the keystone to the springing, and that in proportion to the thickness at the haunches, where fracture takes place; so that whatever the diameter and form of the arch, the strength of good mortar at the end of six months, if the arches are well constructed, is capable of suppressing the thrust as long as the thickness, taken at the middle of the haunches, is stronger than the tenth part of those laid in mortar, and one twelfth of those laid in plaster. Here we have to observe, that arches laid in plaster, as long as they are kept dry and sheltered from the changes of the season, preserve their strength, but, on the contrary, they lose all their stability in seven or eight years, whilst those cemented in mortar endure for ages.

1495. The small quantity of mortar or of plaster used in vaults constructed of wrought stone, in which the joints are often little more than *run*, ought to make an architect cautious of depending merely on the cementing medium for uniting the voussoirs. There are other means which he may employ in cases of doubt, such as *dowels* and *cramps*, means which were much employed by the Romans in their construction; and these are far better than the chains and ties of iron introduced by the moderns.

1496. The thrust of an arch is, in practice, the constant dread of an architect; but it depends entirely on the method employed in the construction. It is only dangerous where the precautions indicated in the foregoing examples are altogether lost sight of. It has

been seen that the least fracture in too thin an arch of equally deep voussoirs may cause its ruin; and we shall here add, that this defect is more dangerous in arches wherein the number of joints is many, such as those constructed in brick; for when they are laid in mortar they are rather heaped together than well fitted to each other.

1497. Whatever materials are used in the construction of vaults, the great object is to prevent separation, which, if it occur, must be immediately met by measures for making the resistance of the lower parts capable of counterbalancing the effort of the upper parts. Those fractures which occur in cylindrical arches are the most dangerous, because they take place in straight lines which run along parallel to the walls bearing them. To avoid the consequences of such failures, it is well to fill up the haunches to the height where the fracture is usually to be found, as in K, K', K'', K''' (fig. 590.) and diminish the thickness towards the key.

1498. Rondelet found, and so indeed did Couplet before him, that the least thickness which an arch of equal voussoirs ought to have, to be capable of standing, was one fiftieth part of the radius. But as the bricks and stone employed in the construction of arches are never so perfectly formed as the theory supposes, the least thickness which can be used for cylindrical arches from 9 to 15 feet radius is  $4\frac{1}{2}$  inches at the vertex if the lower course be laid with a course of brick on edge or two courses flatwise, and 5 inches when the material used is not a very hard stone, increasing the thickness from the keystone to the point where the extrados leaves the walls or piers. But if the haunches are filled up to the point N (fig. 590.), it will be found that for the pointed arch in the figure the thickness need not be more than the  $\frac{1}{13}$  of the radius, and for the semicircular arch,  $\frac{1}{60}$ . For arches whose height is less than their opening or that are segmental the thickness should be  $\frac{1}{2}$  part of the versed sine; a practice also applicable to Gothic vaults and semicircular cylindrical arches, to which for vaults cemented with plaster one line should be added for each foot in length, or  $\frac{1}{14}$  part of the chord subtended by the extrados. With vaults executed in mortar  $\frac{1}{90}$  may be added, the thickness of the arch increasing till it reaches the point N, where the arch becomes detached from the haunches, and where it should be once and a half the thickness of the key. It was in this way the arches throughout the Pantheon at Paris were regulated, and a very similar sort of expedient is practised in the dome of the Pantheon at Rome. A like diminution at the keystone may be used in groined, coved, and spherical vaults.

1499. For vaultings of large openings, Rondelet (and we fully concur with him) thinks wrought stone preferable to brick or rubble stone, because it has the advantage of being liable to less settlement and stands more independent of any cementitious medium employed. It is indeed true that this cannot connect wrought stone so powerfully as it does rubble; but in the former we can employ cramps and dowells at the joints, which are useful in doubtful cases to prevent derangement of the parts. In many Roman ruins the surfaces of the voussoirs were embossed and hollowed at the joints, for the purpose of preventing their sliding upon each other; and expedients of the same nature are frequently found in Gothic ruins.

Fig. 590.

## SECT. X.

## WALLS.

1500. The thickness which is to be assigned to walls and points of support, that their stability may be insured, depends on the weight they have to sustain, and on their formation with proper materials; still more on the proportion which their bases bear to their heights. The crushing of stone and brick, by mere superimposed weight, is of such extremely rare occurrence in practice, even with soft stone and with bad bricks, that we think it sufficient to give the result of the some few experiments that have been made in that respect, to give the reader some notion of the resistance of our bricks and stones to a crushing force. This is exhibited in the subjoined table:—

Materials.	Specific Gravity.	Crushing Weight.
		lbs.
Portland stone, 2 inches long 1 inch high	- - -	805
Statuary marble, 1 inch cube of	- - -	3216
Cragleith stone, ditto	- - -	8688
Chalk, cube of 1½ inch	- - -	1127
Pale red brick, ditto	- - -	1265
Roe stone, Gloucestershire, ditto	- - -	1449
Red brick, ditto	2168	1817
Hammersmith brick, called pavior's ditto	- - -	2254
Ditto burnt, ditto	- - -	3242
Ditto fire-brick, ditto	- - -	3864
Derby grit, ditto	2316	7070
Another specimen, ditto	2428	9776
Killala white freestone, ditto	2423	10,264
Portland, ditto	2428	10,284
Cragleith white freestone, ditto	2452	12,346
Yorkshire paving, with the strata, ditto	2507	12,856
Ditto, ditto, against strata, ditto	- - -	12,856
White statuary marble, ditto	2760	13,632
Bramley Fall sandstone, ditto	2506	13,632
Ditto, against strata, ditto	- - -	13,632
Cornish granite, ditto	2662	14,302
Dundee sandstone, ditto	2530	14,918
Portland, a 2 inch cube	2423	14,918
Cragleith, with the strata, 1½ inch cube	2452	15,360
Devonshire red marble	- - -	16,732
Compact limestone	2584	17,354
Peterhead granite	- - -	18,636
Black compact limestone	2598	19,924
Purbeck	2599	20,610
Freestone, very hard	2528	21,254
Black Brabant marble	2697	20,742
White Italian marble	2726	21,783
Aberdeen granite, blue kind	2625	24,556

1501. The above experiments lose much of their practical value from our knowledge that the interior particles in granulated substances are protected from yielding by the lateral resistance of the exterior ones; but to what extent it is impossible to estimate, because so much depends on the internal structure of the body. We are, however, thus far informed, that, taking into account the weight with which a point of support is loaded, its thickness ought to be regulated in an inverse ratio to the crushing weight of the material employed. In Gothic structures we often see, for instance, in chapter houses with a central column, a prodigious weight superimposed. It is needless to say, that, in such instances, the strongest material was necessary, and we always find it so employed. So, in the columns, or rather pillars, of the naves in such edifices, the greatest care was taken to select the hardest stone.

1502. Generally speaking, the thickness of walls and piers should be proportioned rather to their height than to the weight they are to bear; hence often the employment of a better material, though more costly, is in truth the most economical.

#### *Of the Stability of Walls.*

1503. In the construction of edifices there are three degrees of stability assignable to walls. I. One of undoubted stability; II. A mean between the last; and the III. The least thickness which they ought to possess.

1504. The first case is that in which from many examples we find the thickness equal to one eighth part of the height: a mean stability is obtained when the thickness is one tenth part of the height; and the minimum of stability when one twelfth of its height. We are, however, to recollect that in most buildings one wall becomes connected with another, so that stability may be obtained by considering them otherwise than as independent walls.

1505. That some idea may be formed of the difference between a wall entirely isolated and one connected with one or two others at right angles, we here give *figs.* 591, 592, and 593. It is obvious that in the first case (*fig.* 591.), a wall acted upon by the horizontal force MN, will have no resistance but from the breadth of its base; that in the second

Fig. 591

Fig. 592

case (*fig. 592.*) the wall GF is opposed to the force MN, so that only the triangle of it HIF can be detached; lastly, in *fig. 593.* the force MN would only be effective against

Fig. 593.

the triangle CGH, which would, of course, be greater in proportion to the increased distance of the walls CD, HI.

1506. In the first case, the unequal settlement of the soil or of the construction may produce the effect of the force MN. The wall will fall on the occurrence of an horizontal disunion between the parts.

1507. In the second case the disunion must take place obliquely, which will require a greater effort of the power MN.

1508. In the third case, in order to overturn the wall, there must be three fractures through the effort of MN, requiring a much more considerable force than in the second case.

1509. We may easily conceive that the resistance of a wall standing between two others will be greater or less as the walls CD, HI are more or less distant; so that, in an extreme approximation to one another, the fracture would be impossible, and, in the opposite case, the intermediate wall approaches the case of an isolated wall.

1510. Walls enclosing a space are in the preceding predicament, because they mutually tend to sustain one another at their extremities; hence their thickness should increase as their length increases.

1511. The result of a vast number of experiments by Rondelet, whose work we are still using, will be detailed in the following observations and calculations.

1512. Let ABCD (*fig. 594.*) be the face of one of the walls for enclosing a rectangular

Fig. 594.

Fig. 595.

space, EFGH (*fig. 595*). Draw the diagonal BD, and about B make Bd equal to one eighth part of the height, if great stability be required; for a mean stability, the ninth or tenth part; and, for a light stability, the eleventh or twelfth part. If through the point d a parallel to AB be drawn, the interval will give the thickness to be assigned to the great walls EF, GH, whose length is equal to AD.

1513. The thickness of the walls EG, FH is obtained by making AD' equal to their length, and, having drawn the diagonal as before, pursuing the same operation.

1514. When the walls are of the same height but of different lengths, as in *fig. 596*.,

Fig. 596.

Fig. 597.

the operation may be abridged by describing on the point B (*fig. 597*.) as a centre with a radius equal to one eighth, one tenth, or one twelfth, or such other part of the height as may be considered necessary for a solid, mean, or lighter construction, then transferring their lengths, EF, FG, GH, and HE from A to D, D', D'', and D''' ; and having made the rectangles AC, AC', AC'', and AC''' , draw from the common point B the diagonals BD, BD', BD'', and BD''' , cutting the small circle described on the point B in different points, through which parallels to AB are to be drawn, and they will give the thickness of each in proportion to its length.

1515. In *figs. 598. to 602.* are given the operations for finding the thicknesses of walls

Fig. 598.

Fig. 599.

Fig. 600.

Fig. 601.

Fig. 602.

enclosing polygonal areas supposed to be of the same height; thus AD represents the side of the hexagon (*fig. 602*.); AD' that of the pentagon (*fig. 601*.); AD'' the side of the square (*fig. 599*.); and AD''' that of the equilateral triangle (*fig. 600*.).

1516. It is manifest that, by this method, we increase the thicknesses of the walls in proportion to their heights and lengths; for one or the other, or both, cannot increase or diminish without the same happening to the diagonal.

1517. It is obvious that it is easy to calculate in numbers the results thus geometrically obtained by the simple rule of three; for, knowing the three sides of the triangle ABD,

similar to the smaller triangle  $Bde$ , we have  $BD : Bd :: AD : ed$ . Thus, suppose the length of wall represented by  $AD = 28$  feet, and its height  $AB = 12$  feet, we shall have the length of the diagonal  $= 30$  feet  $5\frac{1}{2}$  inches; and, taking the ninth part of  $AB$ , or 16 inches, as the thickness to be transferred on the diagonal from  $B$  to  $d$ , we have  $30$  ft.  $6$  in. :  $16$  in. ::  $28$  ft. :  $14$  in. :  $8$  lines ( $ed$ ). The calculation may also be made trigonometrically; into which there is no necessity to enter, inasmuch as the rules for obtaining the result may be referred to in the section "Trigonometry," and from thence here applied.

*Method of enclosing a given Area in any regular Polygon.*

1518. It is manifest that a polygon may be divided by lines from the centre to its angles into as many triangles as it has sides. In *fig.* 601., on one of these triangles let fall from  $c$  (which is the vertex of each triangle a perpendicular  $CD$ ) a vertical on the base or side  $AB$  which is supposed horizontal. The area of this triangle is equal to the product of  $DB$  (half  $AB$ ) by  $CD$ , or to the rectangle  $DCFB$ . Making  $DB = x$ ,  $CD = y$ , and the area given  $= p$ , we shall have,

For the equilateral triangle,  $x \times y \times 3 = p$ , or  $xy = \frac{p}{3}$ ;

For the square,  $xy \times 4 = p$ , or  $xy = \frac{p}{4}$ ;

For the pentagon,  $xy \times 5 = p$ , or  $xy = \frac{p}{5}$ ;

For the hexagon,  $xy \times 6 = p$ , or  $xy = \frac{p}{6}$ .

Each of these equations containing two unknown quantities, it becomes necessary to ascertain the proportion of  $x$  to  $y$ , which is as the sines of the angles opposite to the sides  $DB$  and  $CD$ .

1519. In the equilateral triangle this proportion is as the sine of 60 degrees to the sine of 30 degrees; that is, using a table of sines, as 86603 : 50000, or  $8\frac{3}{5}$  : 5, or 26 : 15, whence

$$x : y :: 26 : 15, \text{ and } 15x = 26y; \text{ whence } y = \frac{15x}{26}.$$

Substituting this value in the equation  $xy = \frac{p}{3}$ , we have

$$\frac{15xx}{26} = \frac{p}{3}, \text{ which becomes } xx = \frac{26p}{45}, \text{ and } x = \sqrt{\frac{26p}{45}}.$$

Supposing the area given to be 3600, we shall therefore have

$$x = \sqrt{\frac{3600 \times 26}{45}} = 45.6, \text{ and the side } AB = 91.2.$$

For the pentagon,  $x : y :: \sin. 36^\circ : \sin. 54^\circ$ , or as 58779 : 80902, whence

$$y = \frac{80902x}{58779}.$$

Substituting this value in the equation  $xy = \frac{p}{5}$ , we have

$$\frac{80902xx}{58779} = \frac{3600}{5}, \text{ and } x = \sqrt{\frac{58779 \times 720}{80902}};$$

which makes  $x = 22.87$ , and this side  $AB = 45.74$ .

For the hexagon,  $x : y :: \sin. 30^\circ : \sin. 60^\circ$ , or as 50000 : 86603 :: 5 :  $8\frac{3}{5}$ , whence the value of  $y = \frac{26x}{15}$ . This value, substituted in the equation  $xy = \frac{p}{6}$ , will give  $\frac{26xx}{15} = 600$ ; whence  $xx = \frac{600 \times 15}{26}$ ; lastly, therefore,  $x = \sqrt{346.15} = 18.61$ , and the side  $AB = 37.22$ .

*Geometrically.*

1520. Suppose the case that of a pentagon (*fig.* 601.) one of whose equal triangles is  $ACB$ . Let fall the perpendicular  $CD$ , which divides it into two equal parts; whence its area is equal to the rectangle  $CDBF$ .

1521. Upon the side  $AB$ , prolonged, if necessary, make  $DE$  equal to  $CD$ , and from the middle of  $BE$  as a centre describe the semi-circumference cutting  $CD$  in  $G$ , and  $GD$  will be the side of a square of the same area as the rectangle  $CDBF$ . The sides of similar figures (*Geometry*, 961.) being as the square roots of their areas; find the square root of the given area and make  $Dg$  equal to it. From the point  $g$  draw parallels to  $GE$  and  $GB$ , which will determine on  $AB$  the points  $e$  and  $b$ , which will give on one side  $Db$  equal to one half of the side of the polygon sought; and, on the other, the radius  $De$  of the circumference in which it is inscribed. This is manifest because of the similar triangles  $EGb$  and  $egb$ , from which  $BD : DE :: bD : De$ .

1522. From the truth that the sides of similar figures are to each other as the square roots of their areas we arrive at a simple method of reducing any figure to a given area. Form an angle of reduction (*fig.* 603.) one of whose sides is equal to the square root of the greater area, and the chord of the arc, which determines the size of the angle equal

to the square root of the smaller area. Let, for instance, the larger area = 1156, and that of the smaller, to which the figure is to be reduced, = 529. Draw an indefinite line, on which make  $AB = 34$ , the square root of 1156. Lastly, from the point  $A$ , as a centre, having described an indefinite arc, with a length equal to the square root 23 of 529, set out  $Bg$ ; through  $g$  draw  $Ag$ , which will be the angle of reduction  $gAB$ , by means of which the figure may be reduced, transferring all the measures of the larger area to the line  $AD$ , with which arcs are to be described whose chords will be the sides sought.

Fig. 603.

1523. If it be not required to reduce but to describe a figure whose area and form are given, we must make a large diagram of any area larger than that sought, and then reduce it.

1524. The circle, as we have already observed in a previous subsection (933.), being but a polygon of an infinite number of sides, it would follow that a circular enclosure would be stable with an infinitely small thickness of wall. This property may be easily demonstrated by a very simple experiment. Take, for instance, a sheet of paper, which would not easily be made to stand while extended to its full length, but the moment it is bent into the form of a cylinder it acquires a stability, though its thickness be not a thousandth part of its height.

1525. But as walls must have a certain thickness to acquire stability, inasmuch as they are composed of particles susceptible of separation, we may consider a circular enclosure as a regular polygon of twelve sides, and determine its thickness by the preceding process. Or, to render the operation more simple, find the thickness of a straight wall whose length is equal to one half the radius.

1526. Suppose, for example, a circular space of 56 ft. diameter and 18 ft. high, and the thickness of the wall be required. Describe the rectangle  $ABCD$  (fig. 594.), whose base is equal to half the radius, that is, 14 ft., and whose height  $AB$  is 18 ft.; then, drawing the diagonal  $BD$ , make  $Bd$  equal to the ninth part of the height, that is, 2 ft. Through  $d$  draw  $ad$  parallel to the base, and its length will represent the thickness sought, which is 14½ inches.

1527. By calculation. Add the square of the height to that of half the radius, that is, of  $18 = 324$ , and of  $14 = 196 = 520$ . Then extract the square root of 520, which will be found = 22.8, and this will be the value of the diagonal  $BD$ . Then we have the following proportion:  $22.8 : 14 :: 2 \text{ ft. } (\frac{1}{9} \text{ the height}) : 14.74$ .

1528. The exterior wall of the church of *St. Stefano Rotondo* at Rome (Temple of Claudius) incloses a site 198 feet diameter. The wall, which is constructed of rubble masonry faced with bricks, is 2 ft. 4 in. (French) thick, and 22½ ft. high. In applying to it the preceding rule, we shall find the diagonal of the rectangle, whose base would be the side of a polygon, equal to half the radius and 22½ ft. high, would be  $\sqrt{49\frac{1}{2} \times 49\frac{1}{2} + 22\frac{1}{2} \times 22\frac{1}{2}} = 54\frac{37}{100}$ . Then, using the proportion  $54.37 : 49.5 :: \frac{22\frac{1}{2}}{9} : 2 \text{ ft.}$

3 in. and 4 lines, the thickness sought, instead of 2 ft. 4 in., the actual thickness. We may as well mention in this place that a circle encloses the greatest quantity of area with the least quantity of walling; and of polygons, those with a greater number of sides more than those with a lesser: the proportion of the wall in the circle being 31416 to an area of 78540000; whilst in a square, for the same area, a length of wall equal to 35448 would be required. As the square falls away to a flat parallelogram, say one whose sides are half as great, and the others double the length of those of the square, or 17724 by 4431, in which the area will be about 78540000, as before; we have in such a case a length of walling = 44310.

#### *On the Thickness of Walls in Buildings not vaulted.*

1529. The walls of a building are usually connected and stiffened by the timbers of the roof, supposing that to be well constructed. Some of the larger edifices, such as the ancient basilicæ at Rome, have no other covering but the roof; others have only a simple ceiling under the roof; whereas, in palaces and other habitations, there are sometimes two or more floors introduced in the roof.

1530. We will begin with those edifices covered with merely a roof of carpentry, which are, after mere walls of enclosure, the most simple.

1531. Among edifices of this species, there are some with continued points of support, such as those wherein the walls are connected and mutually support each other; others in which the points of support are not connected with each other, such as piers, columns, and pilasters, united only by arcades which spring from them.

1532. When the carpentry forming the roof of an edifice is of great extent, instead of being injurious to the stability of the walls or points of support, it is useful in keeping them together.

1533. Many edifices exist wherein the walls and points of support would not stand without the aid of the carpentry of the roofs that cover them.

1534. The old basilica of *St. Paolo fuori le mura* at Rome was divided into five naves formed by four ranks of columns connected by arcades, which carried the walls whereon the roof rested; the centre nave 73½ ft. (French) wide, and 93 ft. 10 in. high. The walls of it are erected on columns 31 ft. 9 in. high, and their thickness is a little less than 3 ft., that is, only  $\frac{1}{3}$  part of their height.

1535. At Hadrian's Villa the most lofty walls, still standing, were but sixteen times their thickness in height, and 51 ft. 9 in. long. The walls were the enclosures of large halls with only a single story, but assisted at their ends by cross walls. And we may therefore conclude that if the walls of the basilica above mentioned were not kept in their places by the carpentry of the great roof they would not be safe. It is curious that this supposition, under the theory, was proved by the fire which destroyed the church of *St. Paolo* in 1823. The walls which form the nave of the church of *Santa Sabina* are raised on columns altogether 52 ft. high; they are 145 ft. long, and somewhat less than 2 ft., that is,  $\frac{1}{10}$  part of their height, in thickness. They are, therefore, not in a condition of stability without the aid of the roof. In comparing, however, the thickness of these walls with the height only of the side aisles, in the basilica of *St. Paolo* the thickness is  $\frac{1}{17}$ , and at *Santa Sabina*  $\frac{1}{13}$ . In the other basilicæ or churches with columns, the least thickness of wall is  $\frac{1}{12}$  of greater proportion unconnected with the nave, as at *Santa Maria Maggiore*, *Santa Maria in Trastevere*, *St. Chrysogono*, *St. Pietro in Vincolà*, in Rome; *St. Lorenzo* and *St. Spirito*, in Florence; *St. Filippo Neri*, at Naples; *St. Giuseppe* and *St. Dominico*, at Palermo.

1536. We must take into account, moreover, that the thickness of walls depends as much on the manner in which they are constructed, as on their height and the weight with which they are loaded. A wall of rough or squared stone 12 inches thick, wherein all the stones run right through the walls in one piece, is sometimes stronger than one of 18 or 20 inches in thickness, in which the depth of the stones is not more than half or a third of the thickness, and the inner part filled in with rubble in a bad careless way. We are also to recollect that stability more than strength is oftentimes the safeguard of a building; for it is certain that a wall of hard stone 4 inches thick would be stronger than would be necessary to bear a load equal to four or five stories, where a thickness of 18 inches is used; and yet it is manifest that such a wall would be very unstable, because of the narrowness of the base.

1537. From an examination which Rondelet made of 280 buildings in France and Italy, ancient as well as modern, he found that in those covered with roofs of two inclined sides and constructed in framed carpentry, with and without ceilings, and so trussed as not to act at all horizontally upon the walls, the least thickness in brick or rough stones was  $\frac{1}{4}$  of the width in the clear.

1538. In private houses, divided into several stories by floors, it was observed, generally, that the exterior walls ran from 15 to 24 inches, party walls 16 to 20 inches, and partition walls 12 to 18 inches.

1539. In buildings on a larger scale, exterior walls 2 to 3 feet thick, party walls 20 to 24 inches, partition walls 15 to 20 inches.

1540. In palaces and buildings of great importance, whose ground floors are vaulted, the exterior walls varied from 4 to 9 feet, and the partition walls from 2 to 6 feet. In many of the examples which underwent examination, the thicknesses of the walls and points of support were not always well proportioned to their position, to the space they enclosed, nor to the loads they bore. In some, great voids occur, and considerable loads were supplied with but slender walls and points of support; and in others, very thick walls enclosed very small spaces, and strong points of support had but little to carry.

1541. For the purpose of establishing some method which in a sure and simple manner would determine the thickness of walls in buildings which are not arched, we have considered, says Rondelet, that the tie-beams of the trusses of carpentry whereof the roofs are composed, being always placed in the direction of the width, as well as the girders and leading timbers of floors, serve rather to steady and connect the opposite walls; but, considering the elasticity and flexibility of timber, it is found that they strain the walls which support them in proportion to the widths of the spaces enclosed, whence it becomes often the better plan to determine the thickness of the walls from the width and height of the apartments requisite. Hence the following rules.

#### *First Rule.*

1542. In buildings covered with a simple roof, if the walls are insulated throughout, their height up to the under side of the tie-beams of the trusses, being as shown in *fig. 604*. Having drawn the diagonal BD and thereon made Bb and Dd, equal to the twelfth part of the height AB, then through the points b and d, draw lines parallel to BA and DC, which will bound the thickness of the walls required.

1543. If the height AB and width AD be known, the thickness Ac may be calculated,

saying that  $BD = \sqrt{AB^2 + AD^2}$ ; knowing the value of  $BD$ , we have that of  $cA$  by the proportion  $BD : AD :: Bb : cA = \frac{AD \times Bb}{BD}$ .

#### First Example.

1544. Supposing the width  $AD = 24$  ft., and the height  $AB = 32$ , we shall have

$\sqrt{AB^2 + AD^2} = \sqrt{24 \times 24 + 32 \times 32}$ ; whence  
 $BD = \sqrt{576 + 1024} = \sqrt{1600} = 40$  ft.

$Bb$ , which is the twelfth part of  $AB$ , or of 32 ft. = 2 ft. 8 in.; the thickness of the wall expressed by  $\frac{AD \times Bb}{BD}$ , will be  $\frac{24 \times 2\frac{2}{3}}{40} = 1\frac{1}{3}$  ft., or 1 ft. 7 in. 2 lines, for the thickness sought.

1545. If the walls supporting the roof were stiffened by extra means, such as lower roofs at an intermediate height, as in churches with a nave and side aisles, we may make  $Be$  in the diagonal  $BD$  (fig. 605.) equal to one twelfth of the height above the springing of the side roofs, and  $ef$  a twenty-fourth part of that height below it, and draw through the point  $f$  a line parallel to  $AB$ , which will determine the thickness  $Af'$  sought; or, which amounts to the same thing, add together the total height  $AB$  of the interior, and that of  $EB$  above the point of support,  $E$ , whereof take the twenty-fourth part, which will be equal to  $Be + ef$ .

Fig. 604.

or, which amounts to the same thing, add together the total height  $AB$  of the interior, and that of  $EB$  above the point of support,  $E$ , whereof take the twenty-fourth part, which will be equal to  $Be + ef$ .

#### Second Example.

1546: Fig. 605. is a section of St. Paolo fuori le mura, near Rome, as it was in 1816.

Fig. 605.

The interior height to the under side of the tie-beams is 93 ft. 10 in. (French), whereof 26 ft. 2 in. is the exterior height above the roofs of the side aisles. These two dimensions together make 120 ft., whose twenty-fourth part is 5 ft., to which, on the diagonal  $BD$ , make  $Bf$  equal; then from the point  $f$  letting fall a vertical line, the horizontal line  $Be$  will determine the thickness, which will be 3 ft., the width of the nave being 73 ft. 6 in. In figures, as follows:—

$$BD = \sqrt{93 \text{ ft. } 10 \text{ in.} \times 93 \text{ ft. } 10 \text{ in.} + 73 \text{ ft. } 6 \text{ in.} \times 73 \text{ ft. } 6 \text{ in.}} = \sqrt{14207} = 119 \text{ ft. } 2 \text{ in.}$$

1547. For the thickness,  $eB$ , as before,  $BD : AD :: Bf : Af'$ ; whence,  $Af' = \frac{AD \times Bf}{BD}$   
 $= \frac{73\frac{1}{2} \times 5}{119 \text{ ft. } 2 \text{ in.}} = 3 \text{ ft. } 1 \text{ in.}$ , instead of 2 ft. 11 in. 9 lines, the actual thickness of the walls.

1548. The same calculation being applied to the walls of the nave of Santa Sabina

(Rome), whose height of nave is 51 ft. 2 in., and width 42 ft. 2 in., with a height of 16 ft. of wall above the side aisles, gives 21 in. 4 lines, and they are actually a little less than 24 in.

1549. In the church of Santa Maria Maggiore, the width is 52 ft.  $7\frac{1}{2}$  in., and 56 ft. 6 in. and 4 lines high, to the ceiling under the roof. The height of the wall above the side aisles is 19 ft. 8 in., and the calculation requires the thickness of the walls to be  $26\frac{1}{4}$  in. instead of  $28\frac{1}{2}$  in., their actual thickness.

1550. In the church of St. Lorenzo, at Florence, the internal width of the nave is 37 ft. 9 in., and the height 69 ft. to the wooden ceiling; from the side aisles the wall is 18 ft. high. The result of the calculation is 21 in., and the actual execution 21 in. and 6 lines.

1551. The church of Santo Spirito, in the same city, which has a wooden ceiling suspended to the trusses of the roof, is 76 ft. high and 37 ft. 4 in. wide in the nave the walls rise 19 ft. above the side aisles. From an application of the rule the thickness should be 21 in. 3 lines, and their thickness is  $22\frac{1}{2}$  in.

1552. In the church of St. Filippo Neri, at Naples, the calculation requires a thickness of 21 in., their actual thickness being  $22\frac{1}{2}$  in.

1553. In the churches here cited, the external walls are much thicker; which was necessary, from the lower roofs being applied as *leantoes*, and hence having a tendency, in case of defective framing of them, to thrust out the external walls. Thus, in the church of St. Paolo, the walls are 7 ft. thick, their height 40 ft.; 3 ft. 4 in. only being the thickness required by the rule. A resistance is thus given capable of assisting the walls of the aisles, which are raised on isolated columns, and one which they require.

1554. In the church of Santa Sabina, the exterior wall, which is 26 ft. high, is, as the rule indicates, 26 in. thick; but the nave is flanked with a single aisle only on each side, and the walls of the nave are thicker in proportion to the height, and are not so high. For at St. Paolo the thickness of the walls is only  $\frac{1}{24}$  of the interior width, whilst at Santa Sabina it is  $\frac{1}{21}$ . At San Lorenzo and San Spirito the introduction of the side chapels affords great assistance to the external walls.

#### *Examples for the Thickness of Walls of Houses of many Stories.*

1555. As in the preceding case, the rules which Rondelet gives are the result of observations on a vast number of buildings that have been executed, so that the method proposed is founded on practice as well as on theory.

1556. In ordinary houses, wherein the height of the floors rarely exceeds 12 to 15 ft., in order to apportion the proper thickness to the interior or partition walls, we must be guided by the widths of the spaces they separate, and the number of floors they have to carry. With respect to the external walls, their thickness will depend on the depth and height of the building. Thus a *single* house, as the phrase is, that is, only one set of apartments in depth, requires thicker external walls than a *double* house, that is, more than one apartment in depth, of the same sort and height; because the stability is in the inverse ratio of the width.

1557. Let us take the first of the two cases (*fig. 606.*), whose depth is 24 ft. and height

Fig. 606.

to the under side of the roof 36 ft. Add to 24 ft. the half of the height, 18, and take  $\frac{1}{4}$  part of the sum 42, that is, 21 in., for the least thickness of each of the external walls above the *set-off* on the ground floor. For a mean stability add an inch, and for one still more solid add two inches.

1558. In the case of a double house (*fig. 607.*) with a depth of 42 ft., and of the same height as the preceding example, add half the height to the width of the building; that is, 21 to 18, and  $\frac{1}{24}$  of the sum =  $19\frac{1}{2}$  is the thickness of the walls. To determine the thickness of the partition walls, add to their distance from each other the height of the story, and take  $\frac{1}{36}$  of the sum. Thus, to find the thickness of the wall IK, which divides the space LM into two parts and is 32 ft., add the height of the story, which we will take at 10 ft., making in all 42 ft., and take  $\frac{1}{36}$  or 14 in. Half an inch may be added for each story above the ground floor. Thus, where three stories occur above the ground floor, the thickness in

the lower one would be  $15\frac{1}{2}$  in., a thickness which is well calculated for bricks and stone, whose hardness is of a mean description.

1559. For the wall AB, which divides the space between the external walls, equal to 35 ft., add to it the height, which is 10 ft., and  $\frac{1}{36}$  of 45, the sum of the two; that is, 15 in. is the thickness required for the wall, if only to be carried up a single story; but if through more, then add half an inch, as before, for each story above the ground floor. For the spaces NO, PQ, RS, in this and the preceding figure, the repetition of the operation will give their thicknesses.

1560. To illustrate what has been said, fig. 608. is introduced to the reader, being the plan of a house in the Rue d'Enfer, near the Luxembourg, known as the Hotel Vendôme,

Fig. 607.

Fig. 608.

built by Le Blond. It is given by Daviller in his *Cours d'Architecture*. The building is 46 ft. deep on the right side and 47 ft. in the middle, and is 33 ft. high from the pavement to the entablature. Hence, to obtain the thickness of the walls on the line FF, take the sum of the height and width =  $\frac{47+33}{2} = 40$  ft., whose twenty-fourth part is 20 in. The building being one of solidity, let 2 in. be added, and we obtain 22 in. instead of 2 ft., which is their actual thickness. For the thickness of the interior wall, which crosses the building in the direction of its length, the space between the exterior walls being 42 ft. and the height of each story 14 ft., the thickness of this wall should be  $\frac{42+14}{36} = 18$  in. 8 lines, instead of 18 in., which the architect assigned to it.

1561. By the same mode of operation, we shall find that the thickness of the wall R, separating the salon, which is 22 ft. wide, from the dining-room, which is 18 ft. wide and 14 ft. high, should be 18 in. and 6 lines instead of 18 inches; but as the exterior walls, which are of wrought stone, are 2 ft. thick, and their stability greater than the rule requires, the interior will be found to have the requisite stability without any addition to their thickness.

1562. We shall conclude the observations under this head, by reference to a house built by Palladio for the brothers Mocenigo, of Venice, to be found in his works, and here given (fig. 609.). Most of the buildings of this master are vaulted below; but the one in question is not in that predicament. The width and height of the principal rooms is 16 ft., and they are separated by others only 8 ft. wide, so that the width which each wall separates is  $25\frac{1}{2}$  ft., and their thickness consequently should be  $\frac{25\frac{1}{2}+16}{36} = 13$  in. 10 lines. The walls, as executed,

**Fig. 609.**

are actually 14 in. in thickness. The exterior walls being 24 ft. high, and the depth of the building 46 ft., their thickness by the rule should be  $17\frac{1}{2}$  in. ; they are actually 18 in.

*Of the Stability of Piers, or Points of Support.*

1563. Let ABCD (*fig. 610.*) be a pier with a square base whose resistance is required to be known in respect of a power at M acting upon it to overturn it horizontally in the direction MA, or obliquely in that of NA upon the point D. To render the demonstration more simple, we will consider the solid reduced to a plane passing through G, the centre of gravity of the pier, and the point D, that upon which the power is supposed to cause it to turn. Letting fall from G the vertical cutting the base in I, to which we will suppose the weight of the pier suspended, and then supposing the pier removed, we shall only have to consider the angular lever BDI or HDI, whose arms are determined by perpendiculars drawn from the fulcrum D, in one direction vertical with the weight, and in the other perpendicular to the direction of the power acting upon the pier, according to the theory of the lever explained in a previous section.

**Fig. 610.**

1564. The direction of the weight R being always represented by a vertical let fall from the centre of gravity, the arm of its lever ID never changes, whatever the direction of the power and the height at which it is applied, whilst the arm of the lever of the power varies as its position and direction. That there may be equilibrium between the effort of the power and the resistance of the pier, in the first case, when the power M acts in an horizontal direction, we have  $M : R :: ID : DB$ , whence  $M \times DB = R \times ID$  and  $M = \frac{R \times ID}{DB}$ . If the direction of the power be oblique, as NA in the case of an equilibrium,  $N : R :: ID : DH$ ; hence  $N \times DH = R \times ID$  and  $N = \frac{R \times ID}{DH}$ .

1565. Applying this in an example, let the height of the pier be 12 ft., its width 4 ft., and its thickness 1 ft. The weight R of the pier may be represented by its cube, and is therefore  $12 \times 4 \times 1 = 48$ . The arm of its lever ID will be 2, and we will take the horizontal power M represented by DB at 12; with these values we shall have  $M : 48 :: 2 : 12$ ; hence  $M \times 12 = 48 \times 2$  and  $M = \frac{48 \times 2}{12} = 8$ .

That is, the effort of the horizontal power M should be equal to the weight of 8 cube feet of the materials whereof the pier is composed, to be in equilibrium.

1566. In respect of the oblique power which acts in the direction NA, supposing DH =  $7\frac{1}{2}$ , we have N : 48 :: 2 :  $7\frac{1}{2}$ , whence  $N \times 7\frac{1}{2} = 48 \times 2$ , therefore  $N = \frac{48 \times 2}{7\frac{1}{2}} = 13\frac{1}{2}$ , whilst the

expression of the horizontal power  $M$  was only 8 ft.; but it must be observed, that the arm of the lever is 12, whilst that of the power  $N$  is but  $7\frac{1}{2}$  ft.; but  $13\frac{1}{2} \times 7\frac{1}{2} = 8 \times 12 = 96$ , which is also equal to the resistance of the pier expressed by  $12 \times 4 \times 2 = 96$ . It is moreover essential to observe, that, considering the power  $NA$  as the result of two others,  $MA$  and  $FA$ , the first acting horizontally from  $M$  against  $A$ , tends to overthrow the pier; whilst the second, acting vertically in the direction  $FA$ , partly modifies this effect by increasing the resistance of the pier.

1567. Suppose the power  $NA$  to make an angle of 53 degrees with the vertical  $AF$ , and of 37 degrees with the horizontal line  $AM$ ; then

$$NA : FA : MA :: \text{rad.} : \sin. 37 \text{ deg.} : \sin. 53 \text{ deg.} :: 10 : 6 : 8.$$

Hence,  $NA$  being found =  $13\frac{1}{2}$ , we have  $10 : 6 : 8 :: 13\frac{1}{2} : 8 : 10\frac{3}{4}$ .

Whence it is evident that, from this resolution of the power  $NA$ , the resistance of the pier is increased by the effort of the power  $FA = 8$ , which, acting on the point  $A$  in the direction  $FA$ , will make the arm of its lever  $CD = 4$ , whence its effort =  $8 \times 4 = 32$ .

1568. The resistance of the pier, being thus found = 96, becomes by the effort of the power  $FA = 96 + 32 = 128$ .

1569. The effort of the horizontal power  $M$  being  $10\frac{3}{4}$ , and the arm of its lever being always 12, its effort 128 will be equal to the resistance of the pier, which proves that in this resolution we have, as before, the effort and the resistance equal. The application of this proposition is extremely useful in valuing exactly the effects of parts of buildings which become stable by means of oblique and lateral thrusts.

1570. If it be required to know what should be the increased width of the pier to counterpoise the vertical effort  $FA$ , its expression must be divided by  $ID$ , that is,  $8 \times 2$ , which gives 4 for this increased length, and for the expression of its resistance  $(12 + 4) \times 4 \times 2 = 128$ , as above.

1571. If the effort of the power be known, and the thickness of a pier or wall whose height is known be sought so as to resist it, let the power and parts of the pier be represented by different letters, as follows. Calling the power  $p$ , the height of the pier  $d$ , the thickness sought  $x$ ; if the power  $p$  act in an horizontal direction at the extremity of the wall or pier, its expression will be  $p \times d$ . The resistance of the pier will be expressed by its area multiplied by its arm of lever, that is,  $d \times x \times \frac{x}{2}$ ; and supposing equilibrium, as the resistance must be equal to the thrust, we shall have the equation  $p \times d = d \times x \times \frac{x}{2}$ . Both sides of this equation being divisible by  $d$ , we have  $p = x \times \frac{x}{2}$ ; and as the second term is divided by 2, we obtain  $2p = x \times x$  or  $x^2$ ; that is, a square whose area =  $2p$ , and of which  $x$  is the side or root, or  $x = \sqrt{2p}$ , a formula which in all cases expresses the thickness to be given to the pier  $CD$  to resist a power  $M$  acting on its upper extremity in the horizontal direction  $MA$ .

1572. In this formula, the height of the pier need not be known to find the value of  $x$ , because this height, being common to the pier and the arm of the lever of the power, does not alter the result; for the cube of the pier, which represents its weight, increases or diminishes in the same ratio as the lever. Thus, if the height of the pier be 12, 15, or 24 ft., its thickness will nevertheless be the same.

Example. — If the horizontal power expressed by  $p$  in the formula  $x = \sqrt{2p}$  be 8, we have  $x = \sqrt{16} = 4$  for the thickness of the pier. Whilst the power acting at the extremity of the pier remains the same, the thickness is sufficient, whatever the height of the pier. Thus for a height of 12 ft. the effort of the power will be  $8 \times 12 = 96$ , and the resistance  $12 \times 4 \times 2 = 96$ . If the pier be 15 ft. high, its resistance will be  $15 \times 4 \times 2 = 120$ , and the effort of the power  $8 \times 15 = 120$ . Lastly, if the height be 24 ft., the resistance will be  $24 \times 4 \times 2 = 192$ , and the effort of the power  $8 \times 24 = 192$ .

1573. If the point on which the horizontal force acts is lower than the wall or pier, the difference may be represented by  $f$ ; and then  $p \times (d - f) = d \times x \times \frac{x}{2}$ ;

$$\text{Which becomes } 2pd - 2pf = dxx \text{ and } 2p - \frac{2pf}{d} = xx;$$

$$\text{Lastly } x = \sqrt{2p - \frac{2pf}{d}}.$$

$$\text{Suppose } p = 9. f = 6 \text{ and } d = 12,$$

the formula becomes  $x = \sqrt{18 - \frac{18 \times 6}{12}} = \sqrt{9} = 3$ , which is the thickness sought.

1574. When the power  $NA$  is oblique, the thickness may be equally well found by the arm of lever  $DH$ , by resolving it into two forces, as before. Thus, in the case of the oblique power  $p = 13\frac{1}{2}$ , calling  $f$  its arm of lever  $7\frac{1}{2}$ , we shall have  $p \times f = \frac{dxx}{2}$ , which will become  $\frac{2pf}{d} = xx$ , whence  $x = \sqrt{\frac{2pf}{d}}$ ; in which, substituting the known values, we have  $x = \sqrt{\frac{2 \times 13\frac{1}{2} \times 7\frac{1}{2}}{12}}$ ; whence  $x = \sqrt{16} = 4$ , the thickness sought of the pier.

1575. In resolving the oblique effort NA into two forces, whereof one MA tends to overturn the pier by acting in an horizontal direction, and the other fA to strengthen it by acting vertically, as before observed; let us represent the horizontal effort MA by  $p$ , its arm of lever, equal to the height of the pier, by  $d$ , the vertical effort fA by  $n$ ; the arm of lever of the last-named effort, being the thickness sought, will be  $x$ ; from which we have the equation

$$pd = \frac{dx}{d} + nx, \text{ or } 2p = xx + \frac{2nx}{d}.$$

1576. As the second member of this equation is not a perfect square, let there be added to each side the term wanting, that is, the square  $\frac{nn}{dd}$ , the half of the quantity  $\frac{2n}{d}$ , which multiplied  $x$  in the second term, whence

$$2p + \frac{nn}{dd} = xx + \frac{2nx}{d} + \frac{n}{d}.$$

1577. The second member, by this addition, having become a square whose root is  $x + \frac{n}{d}$ , we shall have  $x + \frac{n}{d} = \sqrt{2p + \frac{nn}{dd}}$  and lastly  $x = \sqrt{2p + \frac{nn}{dd}} - \frac{n}{d}$  will be the general formula for finding the thickness  $x$ .

#### *Application of the Formula.*

1578. Let  $p = 10\frac{1}{2}$ ,  $n = 8$ ,  $d = 12$ . Substituting these values in the formula, it will become  $x = \sqrt{10\frac{1}{2} \times 2 + \frac{64}{144}} - \frac{8}{12} = \sqrt{21\frac{1}{2} + \frac{4}{9}} - \frac{2}{3} = \sqrt{21 + \frac{7}{9}} - \frac{2}{3} = 4$ .

1579. If, for proof, we wish to calculate the expression of the resistance, by placing in the equation of equilibrium  $2pd = dx \times nx$ , the values of the quantities  $p$ ,  $d$ , and  $x$ , above found, we shall have

$$10\frac{1}{2} \times 12 = 12 \times 4 \times 2 + 8 = 128, \text{ as was previously found for FA.}$$

1580. From the preceding rules, it appears that all the effects whose tendency is to destroy an edifice, arise from weight acting in an inverse ratio to the obstacles with which it meets. When heavy bodies are merely laid on one another, the result of their efforts is a simple pressure, capable of producing settlement or fracture of the parts acted upon.

1581. Foundations whose bases are spread over a much greater extent than the walls imposed upon them, are more susceptible of settlement than of crushing or fracture. But isolated points of support in the upper parts, which sometimes carry great weights on a small superficies, are susceptible both of settlement and crushing, whilst the weight they have to sustain is greater than the force of the materials whereof they are formed; which renders the knowledge of the strength of materials an object of consequence in construction. Till of late years it was not thought necessary to pay much attention to this branch of construction, because most species of stone are more than sufficiently hard for the greatest number of cases. Thus, the abundant thickness which the ancients generally gave to all the parts of their buildings, proves that with them this was not a subject of consideration; and the more remotely we go into antiquity, the more massive is the construction found to be. At last, experience taught the architect to make his buildings less heavy. Columns, which among the Egyptians were only 5 or 6 diameters high, were carried to 9 diameters by the Greeks in the Ionic and Corinthian orders. The Romans made their columns still higher, and imparted greater general lightness to their buildings. It was under the reign of Constantine, towards the end of the empire, that builders without taste carried their boldness in light construction to an extraordinary degree, as in the ancient basilicæ of St. Peter's at Rome and St. Paolo fuori le mura. Later, however, churches of a different character, and of still greater lightness, were introduced by the Gothic architects.

1582. The invention and general use of domes created a very great load upon the supporting piers; and the earlier architects, fearful of the mass to be carried, gave their piers an area of base much greater than was required by the load supported, and the nature of the stone used to support it. They, moreover, in this respect, did little more than imitate one another. The piers were constructed in form and dimensions suited rather to the arrangement and decoration of the building that was designed, than to a due apportionment of the size and weight to the load to be borne; so that their difference from one another is in every respect very considerable.

The piers bearing the dome of St. Peter's at Rome are loaded with a weight of 14·964 tons for every superficial foot of their horizontal section.

The piers bearing the dome of St. Paul's at London are loaded with a weight of 17·705 tons for every superficial foot of their horizontal section.

The piers bearing the dome of the Hospital of Invalids at Paris are loaded with a weight of 13·598 tons for every superficial foot of their horizontal section.

The piers bearing the dome of the Pantheon (St. Geneviève) at Paris are loaded with a weight of 26·934 tons for every superficial foot of their horizontal section.

The columns of St. Paolo fuori le mura, near Rome, are loaded with a weight of 18·123 tons for every superficial foot of their horizontal section

In the church of St. Méry, the piers of the tower are loaded with upwards of 27 tons to the superficial foot. With such a discrepancy, it is difficult to say, without a most perfect knowledge of the stone employed, what should be the exact weight per foot. The dome of the Hospital of the Invalids seems to exhibit a maximum of pier in relation to the weight, and that of the Pantheon at Paris a minimum. All the experiments (scanty, indeed, they are) which we can present to the reader are those given at the beginning of this section. In this country, the government has always been too much employed in considering how long it can keep itself in place, to have time to consider how the services of its members could benefit the nation by the furtherance of science. An exactly opposite conduct has always marked the French government: hence more scientific artists are always found amongst them than we can boast here, where the cost of experiments invariably comes out of the artist's pocket.

*Ratio of the Points of Support in a Building to its total Superficies.*

1583. In the pages immediately preceding, we have, with Rondelet for our guide, explained the principles whereon depend the stabilities of walls and points of support, with their application to different sorts of buildings. Not any point relating to construction is of more importance to the architect. Without a knowledge of it, and the mode of even generating new styles from it, he is nothing more than a pleasing draughtsman at the best, whose elevations and sections may be very captivating, but who must be content to take rank in about the same degree as the portrait painter does in comparison with him who paints history. Hereafter will be given the method of properly covering the walls, one which has occupied so much of our space; namely, when we treat of the subject of Roofs, and the method of framing them. It is equally important, and of as high value to the architect, as that which we are now quitting, to which we regret our limits do not allow us to add more: but previous to leaving it, we must subjoin a table of great instruction, showing the ratio of the points of support to the total superficies covered in some of the principal buildings of Europe.

TABLE SHOWING THE RATIO OF THE WALLS AND POINTS OF SUPPORT OF THE PRINCIPAL EDIFICES OF EUROPE TO THE TOTAL AREA WHICH THEY OCCUPY.

Names of Edifices.	Total Area of the Building in English superficial feet.	Total Area of the Points of Support in English superficial feet.	Ratio in Thousandths of the Points of Support to the total Area.
The Pantheon at Rome - - -	34,328	7,954	0.232
Temple of Peace at Rome - - -	67,123	8,571	0.127
Great temple at Pæstum - - -	15,353	2,649	0.172
Ancient temple, Galuzzo, at Rome - - -	9,206	2,167	0.235
Temple of Concord, Girgenti, Sicily - - -	6,849	1,330	0.194
Temple of Juno Lucina, Sicily - - -	6,821	1,110	0.163
Central building of the baths of Caracalla - - -	275,503	48,911	0.176
Central building of the baths of Diocletian - - -	351,636	58,797	0.167
Temple of Claudius at Rome, now church of S. Stefano - - -	36,726	2,051	0.056
Mosque of S. Sophia at Constantinople - - -	103,200	22,567	0.217
Basilica of S. Paolo fuori le mura (Rome), 1816 - - -	106,513	12,655	0.118
Duomo of S. Maria del fiore at Florence - - -	84,802	17,030	0.201
Duomo of S. Maria del fiore at Milan - - -	125,853	21,635	0.169
St. Peter's at Rome, as executed - - -	227,069	59,308	0.261
St. Peter's at Rome, as projected by Bramante - - -	213,610	46,879	0.219
Church of S. Vitale at Ravenna - - -	7,276	1,142	0.157
Church of S. Pietro a Vincola, Rome - - -	21,520	3,353	0.155
Church of S. Sabino — destroyed - - -	15,139	1,543	0.100
Church of S. Domenico, Palermo - - -	34,144	4,988	0.146
Church of S. Giuseppe, Palermo - - -	26,046	3,611	0.139
Church of S. Filippo Neri, Naples - - -	22,826	2,944	0.129
Church of St. Paul's, London - - -	84,025	14,311	0.170
Church of Notre Dame, Paris - - -	67,343	8,784	0.140
Hotel of the Invalids, Paris - - -	29,003	7,790	0.268
Church of S. Sulpice, Paris - - -	60,760	9,127	0.151
Church of S. Geneviève, Paris - - -	60,287	9,269	0.154

The above table exhibits also the comparative sizes of the different buildings named in it.

*Pressure of Earth against Walls.*

1584. It is not our intention to pursue this branch of the practice of walling to any extent, the determination of the thickness of walls in this predicament being more useful, perhaps, to the engineer than to the architect. We shall therefore be contented with but a concise mention of it. Rondelet has (with, as we consider, great judgment) adopted the theory of Belidor, in his *Science des Ingenieurs*, and we shall follow him. Without the slightest disrespect to later authors, we know from our own practice that walls of *Revêtement* may be built, with security, of much less thickness than either the theories of Belidor, or, latterly, of modern writers require. We entirely leave out of the question the rules of Dr. Hutton in his *Mathematics*, as absurd and incomprehensible. The fact is, that in carrying up walls to sustain a bank of earth, nobody, in the present day, would dream of constructing them without carefully ramming down the earth, layer by layer, as the wall is carried up, so as to prevent the weight of the earth, in a triangular section, pressing upon the wall, which is the foundation of all the theory on the subject. With this qualification, therefore, we shall proceed; premising, that if the caution whereof we speak be taken, the thickness resulting from the following investigations will be much more than the outside of enough.

1585. Earth left to itself takes a slope proportionate to its consistence; but for our purpose it will sufficiently exhibit the nature of the investigation, to consider the substance pressing against the wall as dry sand or pounded freestone, which will arrange itself in a slope of about  $55\frac{1}{2}^\circ$  with the vertical plane, and therefore of  $34\frac{1}{2}^\circ$  with an horizontal plane, as Rondelet found to be the case when experimenting on the above materials in a box, one of whose sides was removable. Ordinarily,  $45^\circ$  is taken as the mean slope into which earths recently thrown up will arrange themselves.

1586. Belidor, in order to form an estimate for the thrust or pressure into which we are inquiring, divides the triangle EDF (*fig. 611.*) representing the mass of earth which creates the thrust, by parallels to its base ED, forming slices or sections of equal thickness and similar form; whence it follows, that, taking the first triangle  $aFb$  as unity, the second slice will be 3, the third 5, the fourth 7, and so on in a progression whose difference is 2.

1587. Each of these sections being supposed to slide upon an inclined plane parallel to ED, so as to act upon the face FD, if we multiply them by the mean height at which they collectively act, the sum of the products will give the total effort tending to overturn the wall; but as this sum is equal to the product of the whole triangle by the height determined by a line drawn from its centre of gravity parallel to the base, this last will be the method followed, as much less complicated than that which Belidor adopts, independent of some of that author's suppositions not being rigorously correct.

1588. The box in which the experiment was tried by Rondelet was  $16\frac{1}{2}$  in. (French) long, 12 in. wide, and  $17\frac{1}{2}$  in. high in the clear. As the slope which the pounded freestone took when unsupported in front formed an angle with the horizon of  $34\frac{1}{2}^\circ$ , the height AE is  $11\frac{1}{3}$ , so that the part acting against the front, or that side of the box where would be the wall, is represented by the triangle EDF.

1589. To find by calculation the value of the force, and the thickness which should be given to the opposed side, we must first find the area of the triangle  $EDF = \frac{16\frac{1}{2} \times 11\frac{1}{3}}{2} = 93\frac{1}{2}$ ; but as the specific gravity (or equal mass) of the pounded stone is only  $\frac{1}{3}$  of that of the stone or other species of wall which is to resist the effort, it will be reduced to  $73\frac{1}{2} \times \frac{1}{3} = 81$ . This mass being supposed to slide upon the plane ED, its effort to its weight will be as AE is to ED ::  $11\frac{1}{3} : 20$ , or  $81 \times \frac{11\frac{1}{3}}{20} = 45.9$ , which must be considered as the oblique power  $qr$  passing through the centre of gravity of the mass, and acting at the extremity of the lever  $ik$ . To ascertain the length of the lever, upon whose length depends the thickness of the side which is unknown, we have the similar triangles  $qsr$ ,  $qho$ , and  $kio$ , whose sides are proportional: whence  $qs : sr :: qh : ho$ ; and as  $ko = hk - ho$ , we have  $qr : rs :: hk - ho : if$ .

$$\text{Whence, } if = \frac{(hk - ho) \times qs}{qr},$$

The three sides of the triangle  $qsr$  are known from the position of the angle  $q$  at the centre of gravity of the great triangle EFD, whence each of the sides of the small triangle is equal to one third of those of the larger one, to which it is correspondent.

strength; but after what we have said in the beginning of this article, on the dependence that is to be placed rather on well ramming down each layer of earth at the back of the wall, supposing it to be of ordinary thickness, we do not think it necessary to enter upon any calculation relative to their employment. It is clear their use tends to diminish the requisite thickness of the wall, and we would rather recommend the student to apply himself to the knowledge of what has been done, than to trust to calculation for stability, though we think the theory ought to be known by him.

## SECT. XI.

## MECHANICAL CARPENTRY.

1593. The woods used for the purposes of carpentry merit our attention from their importance for the purpose of constructing solid and durable edifices. They are often employed to carry great weights, and to resist great strains. Under these circumstances, their strength and dimensions should be proportioned to the strains they have to resist. For building purposes, oak and fir are the two sorts of timber in most common use. Stone has, doubtless, the advantage over wood: it resists the changes of moisture and dryness, and is less susceptible of alteration in the mass; hence it ensures a stability which belongs not to timber. The fragility of timber is, however, less than that of stone, and its facility of transport is far greater. The greatest inconvenience attending the use of timber, is its great susceptibility of ignition. This has led, in this as in every age, to expedients for another material, and in public buildings the object may be attained. In private buildings, the cost of the substitute will not permit the employment of other than the material which is the subject of our section.

1594. Oak is one of the best woods that can be employed in carpentry. It has all the requisite properties; such as size, strength, and stiffness. Oaks are to be found capable of furnishing pieces 60 to 80 ft. long, and 2 ft. square. In common practice, beams rarely exceed 36 to 40 ft. in length, by 2 ft. square.

1595. In regard to its durability, oak is preferable to all other trees that furnish equal lengths and scantlings: it is heavier, better resists the action of the air upon it, as well as that of moisture and immersion in the earth. It is a saying relating to the oak, that it grows for a century, lasts perfect for a century, and takes a century to perish. When cut at a proper season, used dry, and protected from the weather, it lasts from 500 to 600 years. Oak, like other trees, varies in weight, durability, strength, and density, according to the soil in which it grows. The last is always in an inverse proportion to the slowness of its growth; trees which grow slowest being invariably the hardest and the heaviest.

1596. From the experiments made upon oak and other sorts of wood, it is found that their strength is proportional to their density and weight; that of two pieces of the same species of wood, of the same dimensions, the heavier is usually the stronger.

1597. The weight of wood will vary in the same tree; usually the heaviest portions are the lower ones, from which upwards a diminution of weight is found to occur. In full-grown trees, however, this difference does not occur. The oak of France is heavier than that of England; the specific gravity of the former varying from 1000 to 1054, whilst the latter, in the experiments of Barlow, varies from 770 to 920. The weight, therefore, of an English cube foot of French oak is about 58 English pounds. Timber may be said to be well seasoned when it has lost about a sixth part of its weight.

1598. In carpentry, timber acts with an absolute and with a relative strength. For instance, that called the absolute strength is measured by the effort that must be exerted to break a piece of wood by pulling it in the direction of the fibres. The relative strength of a piece of wood depends upon its position. Thus a piece of wood placed horizontally on two points of support at its extremities, is easier broken, and with a less effort, than if it was inclined or upright. It is found that a smaller effort is necessary to break the piece as it increases in length, and that this effort does not decrease strictly in the inverse ratio of the length, when the thicknesses are equal. For instance, a piece 8 ft. long, and 6 in. square, placed horizontally, bears a little more than double of another, of the same depth and thickness, 16 ft. long, placed in the same way. In respect of the absolute force, the difference does not vary in the same way with respect to the length. The following are experiments by Rondelet, to ascertain the absolute force, the specimen of oak being of 861 specific gravity, and a cube foot, therefore, weighing  $49\frac{1}{10}$  lbs.

*Cohesive Force of Pieces drawn in the Direction of their Length.*

## First experiment.

A small rod of oak 0·0888 in. (= 1 French line) square, and 2·14 in. in length, broke with a weight of	-	-	-	115 lbs. averdupois.
Another specimen of the same wood, and of similar dimensions, broke with	-	-	-	105 $\frac{8}{10}$
Another specimen	-	-	-	110 $\frac{1}{16}$
The mean weight, therefore, was, in round numbers, 110 lbs.				
A rod of the same wood as the former, 0·177 inch (= 2 French lines) square, and 2·14 inches long, broke with a weight of	-	-	-	439 $\frac{1}{2}$ lbs. averdupois.
Another specimen	-	-	-	418
Another specimen	-	-	-	451 $\frac{1}{2}$

The mean weight, therefore, was 436 lbs. for an area  $\frac{35}{100}$  in. (= 4 square lines French, or 110 lbs. for each, French line = 0·0888 in. English).

1599. Without a recital of all the experiments, we will only add, that after increasing the thickness and length of the rods in the several trials, the absolute strength of oak was found to be 110 lbs. for every  $\frac{888}{10000}$  of an inch area (= 1 French line superficial).

*The Strength of Wood in an upright Position.*

1600. If timber were not flexible, a piece of wood placed upright as a post, should bear the weights last found, whatever its height; but experience shows that when a post is higher than six or seven times the width of its base, it bends under a similar weight before crushing or compressing, and that a piece of the height of 100 diameters of its base is incapable of bearing the smallest weight. The proportion in which the strength decreases as the height increases, is difficult to determine, on account of the different results of the experiments. Rondelet, however, found, after a great number, that when a piece of oak was too short to bend, the force necessary to crush or compress it was about 49·72 lbs. for every  $\frac{888}{10000}$  of a square inch of its base, and that for fir the weight was about 56·16 lbs. Cubes of each of these woods, on trial, lost height by compression, without disunion of the fibres; those of oak more than a third, and those of fir one half.

1601. A piece of fir or oak diminishes in strength the moment it begins to bend, so that the mean strength of oak, which is 47·52 lbs. for a cube  $\frac{888}{10000}$  of an inch, is reduced to 2·16 lbs. for a piece of the same wood, whose height is 72 times the width of its base. From many experiments, Rondelet deduced the following progression:—

For a cube, whose height is	1,	the strength =	1
—	12,	—	= $\frac{5}{6}$
—	24,	—	= $\frac{1}{2}$
—	36,	—	= $\frac{1}{3}$
—	48,	—	= $\frac{1}{4}$
—	60,	—	= $\frac{1}{5}$
—	72,	—	= $\frac{1}{6}$

Thus, for a cube of oak, whose base is 1·066 in. area (= 1 square in. French) placed upright, that is, with its fibres in a vertical direction, its mean strength is expressed by  $144 \times 47 \cdot 52 = 6842$  lbs. From a mean of these experiments, the result was (by experiment) in lbs. averdupois - - - 6853

For a rod of the same oak, whose section was of the same area by 12·792 in. high (= 12 French in.), the weight borne or mean strength is  $144 \times \frac{47 \cdot 52 \times 5}{6} = 5702$  lbs.

From a mean of three experiments, the result was - - - 5735

For a rod 25·584 (= 24 French) in. high, the strength is  $144 \times \frac{47 \cdot 52}{9} = 3421$  lbs. - 3144

For a rod 38·376 (= 36 French) in. high, the strength is  $144 \times \frac{47 \cdot 52}{3} = 2281$  lbs. - 2336

For a rod 51·160 (= 48 French) in. high, the strength is  $144 \times \frac{47 \cdot 52}{6} = 1140$  lbs.

For a rod 63·960 (= 60 French) in. high, the strength is  $144 \times \frac{47 \cdot 52}{12} = 570$  lbs.

For a rod 76·752 (= 72 French) in. high, the strength is  $144 \times \frac{47 \cdot 52}{24} = 285$  lbs.

For a cube of fir, whose sides are 1·066 in. area (= 1 square in. French), placed as before, with the fibres in a vertical direction, we have  $144 \times 56 \cdot 16 = 8087$  lbs. - 8089

\* The French inch, consisting of 144 lines.

For a square rod, whose base was 1·066 in. area (=1 square in. French), 12·792 in.

high, we have  $144 \times \frac{56 \cdot 16 \times 5}{6} = 6739$  lbs. - - - 6863

For a rod 25·584 (=24 French) in. high,  $144 \times \frac{56 \cdot 16}{2} = 4043$  lbs. - - 3703

For a rod 38·376 (=36 French) in. high,  $144 \times \frac{56 \cdot 16}{3} = 2696$  lbs. - - 2881

For a rod 51·160 (=48 French) in. high,  $144 \times \frac{56 \cdot 16}{6} = 1348$  lbs.

For a rod 63·960 (=60 French) in. high,  $144 \times \frac{56 \cdot 16}{12} = 674$  lbs.

For a rod 76·752 (=72 French) in. high,  $144 + \frac{56 \cdot 16}{24} = 337$  lbs.

The rule by Rondelet above given was that also adopted by MM. Perronet, Lamblardie, and Girard. In the analytical treatise of the last-named, some experiments are shown, which lead us to think it not very far from the truth. From the experiments, moreover, we learn, that the moment a post begins to bend, it loses strength, and that it is not prudent, in practice, to reduce its diameter or side to less than one tenth of its height.

1602. In calculating the resistance of a post after the rate of only 10·80 for every 1·066 superficial line English (=1 line super. French), which is much less than one quarter of the weight under which it would be crushed, we shall find that a square post whose sides are 1·066 ft. (=1 ft. French) containing 22104·576 English lines (=20736 French), would sustain a weight of 238729 lbs. or 106 tons. Yet as there may be a great many circumstances, in practice, which may double or triple the load, it is never safe to trust to a post the width of whose base is less than a tenth part of its height, to the extent of 5 lbs. per 1·066 line; in one whose height is fifteen times the width of the base, 4 lbs. for the same proportion; and when twenty times, not more than 3 lbs.

#### *Horizontal Pieces of Timber.*

1603. In all the experiments on timber lying horizontally, as respects its length, and supported at the ends, it is found that, in pieces of equal depth, their strength diminishes in proportion to the bearing between the points of support. In pieces of equal length between the supports, the strength is as their width and the squares of their depths. We here continue M. Rondelet's experiments.

1604. A rod of oak 2·132 in. (2 in. French) square, and 25·584 in. (24 in. French) long, broke under a weight of 2488·32 lbs., whilst another of the same dimensions, but 19·188 in. (18 in. French) bore 3353·40; whence it appears that the relative strength of these two rods was in the inverse ratio of their length. The proportion is 19·188 : 25·584 :: 2488·32 : 3317·76, instead of 3353·40 lbs., the actual weight in the experiment.

1605. In another rod of the same wood, 2·132 in. wide and 3·198 deep, and 25·584 in. bearing, it broke with a weight of 5532 lbs. In the preceding first-mentioned experiment it was found that a rod of 2·132 in. square, with a bearing 25·584 in. bore 2488·32 lbs. Supposing the strength of the rods to be exactly as the squares of their heights, we should have 4·54 (2·132<sup>2</sup>) : 10·23 (3·198<sup>2</sup>) :: 2488·32 : 5598·7 lbs.; which the second rod should have borne, instead of 5532 lbs. There are numberless considerations which account for the discrepancy, but it is one too small to make us dissatisfied with the theory.

1606. In a third experiment on the same sort of wood, the dimension of 3·198 in. being laid flatwise, and the 2·132 in. depthwise, the bearing or distance between the supports being the same as before, it broke with a weight of 3573 lbs. : whence it follows that the strength of pieces of wood of the same depth is proportional to their width. Thus, comparing the piece 2·132 in. square, which bore 2488 lbs., we ought to have 2·132 : 3·198 :: 2488·32 : 3624·48, instead of 3573 lbs.

1607. From a great number of experiments and calculations made for the purpose of finding the proportion of the absolute strength of oak, to that which it has when lying horizontally between two points of support, the most simple method is to multiply the area of the piece in section by half the absolute strength, and to divide the product by the number of times its depth is contained in the length between the points of support.

1608. Thus, in the experiments made by Belidor on rods of oak 3 French (=3·198 English) ft. long, and 1 French (=1·066 in. English) in. square, the mean weight under which they broke was 200·96 lbs. averdupois. Now, as the absolute strength of oak is from 98 to 110 lbs. for every  $\frac{888}{100000}$  in. (=1 French line), the mean strength will be 104 and 52 lbs. for its half, and the rule will become (144 lines, being =1 French in.)  $\frac{144 \times 52}{36 \text{ (F. in.)}} = 207 \cdot 30$  lbs., instead of 200·96 lbs.

1609. Three other rods, 2 French in. square (2·132 Eng.), and of the same length between the supports, broke with a mean weight of 1711·8 lbs. By the rule  $\frac{576 (=144 \times 4) \times 52}{18} = 1658 \cdot 88$  lbs. averdupois. Without further mention of the experiments of Belidor, we

may observe, that those of Parent and others give results which confirm the rule. The experiments, however, of Buffon, having been made on a larger scale, show that the strength of pieces of timber of the same size, lying horizontally, does not diminish exactly in the proportion of their length, as the theory whereon the rule is founded would indicate. It becomes, therefore, proper to modify it in some respects.

1610. Buffon's experiments show that a beam as long again as another of the same dimensions will not bear half the weight that the shorter one does. Thus —

A beam, 7·462 ft. long, and 5·330 in. square, broke with a weight of	-	-	-	-	12495·06 lbs. averdupois.
Another, 14·924 ft. long, of the same dimensions, broke with a weight of	-	-	-	-	5819·04
A third, 29·848 ft. long, of the same dimensions, bore before breaking	-	-	-	-	2112·48
By the rule, the results should have been, for the 7·462 ft. beam					12495·60
				for that of 14·924	6247·80
				for that of 29·848	3123·90

Whence it appears, that owing to the elasticity of the timber, the strength of the pieces, instead of forming a decreasing geometrical progression, whose exponent is the same, forms one in which it is variable. The forces in question may be represented by the ordinates of a species of catenarean curve.

1611. In respect, then, of the diminution of the strength of wood, it is not only proportioned to the length and size, but is, moreover, modified in proportion to its absolute or primitive force and its flexibility; so that timber exactly of the same quality would give results following the same law, so as to form ordinates of a curve, exhibiting neither inflection nor undulation in its outline: thus in pieces whose scantlings and lengths form a regular progression, the defects can only be caused by a difference in their primitive strength; and as this strength varies in pieces taken from the same tree, it becomes impossible to establish a rule whose results shall always agree with experiment; but by taking a mean primitive strength, we may obtain results sufficiently accurate for practice. For this purpose, the rule that nearest agrees with experiment is —

- 1st. To subtract from the primitive strength one third of the quantity which expresses the number of times that the depth is contained in the length of the piece of timber.
- 2d. To multiply the remainder thus obtained by the square of the length.
- 3d. To divide the product by the number expressing the relation of the depth to the length.

Hence calling the primitive strength	-	-	-	= $a$
— the number of times that the depth is contained in the length	-	-	-	= $b$
— the depth of the piece	-	-	-	= $d$
— the length	-	-	-	= $l$

The general formula will be, 
$$a - \frac{b}{3} \times dd = \frac{add}{b} - \frac{dd}{3}.$$

1612. Suppose the primitive strength  $a = 64·36$  for each 1·136 square line (=1 line French), we shall find for a beam 5·330 in. square, by 19·188 ft. long, or 230·256 inches, that the proportion of the depth to the length =  $\frac{230·256}{5·330} = 43·2 = b$ .

1613. The vertical depth being 5·330 or 63·960 lines,  $dd$  will be 4089·88; substituting these values in the formula  $\frac{a \times dd}{b} - \frac{dd}{3}$  we have  $\frac{64·36 \times 4089·88}{43·2} - \frac{4089·88}{3} = 4067·99$ , instead of 4120·20, the mean result of two beams of the same scantlings in the experiments of Buffon. But as the mean primitive strength of the beams is, according to the second of the following tables, 64·99, instead of 64·36, which has been taken for the mean strength of all the pieces given in that table, we ought to have found less. Thus taking 64·99, we have  $\frac{64·99 \times 4089·88}{43·2} - \frac{4089·88}{3} = 4120·20$ , as in the experiment.

The scientific world generally, the architect and engineer especially, are indebted to the person from whom the tables which follow have emanated. They are worth more than all which hitherto has been done in this country; and our surprise is great that in most of the various treatises on timber and carpentry, some whereof have resulted from no mean hands, more importance has been given to theoretical instruction than to that which might have been deduced from experiments. The treatises, indeed, on mechanical carpentry almost seem to have been written more with the view of perplexing than of assisting the student.

## TABLES OF EXPERIMENTS.

TABLE I.

Experiments on Pieces of Timber 4·264 inches square, supposing the absolute Strength 60·1344.

Length of the Pieces in Feet.	Proportion of Depth to Length.	Weight of the Pieces in Pounds.	Curvature before breaking, in Inches.	Absolute Strength.	Relative Strength.	Weight in Pounds avoirdupois.	Mean Effort according to Experiment.	Relative Strength according to Calculation.	Breaking Weight calculated on relative Strength.
				From Experiment.					
7·462	21	{ 64·80 60·48 73·44	{ 3·721 4·797 3·997	60·13	52·57	{ 5778 5697 4968	5768	52·57	5768

21·320	30			54·10	43·30		13,303	44·28	13,593

1614. The five preceding tables give a view of the results of experiments by Buffon upon beams 4·264, 5·330, 6·396, 7·462, and 8·528 inches square, of different lengths, as compared with those found by the modified rule above given (1660.).

1615. The first column shows the length of the pieces in English feet. The second, the proportion of their depth to their length. The third, the weight of each piece in pounds averted. The fourth, the curvature before breaking. The fifth, the absolute or primitive strength, that is, independent of the length. The sixth, that strength reduced in the ratio of the proportion of the depth to the length of the pieces given in the

second column. The seventh column gives the weight borne before breaking, independent of their own weight. The eighth, the mean effort with which the pieces broke, including half their weight, the other half acting on the points of support. The ninth shows the reduced strength of the pieces in respect of the proportions of the depth to the length, supposing the primitive strength equal for all the pieces in the same table. The tenth column gives the result of the calculation according to the rule above given.

1616. In order to give an idea of the method of representing the strength of wood of the same scantling, but of different lengths, by the ordinates of a curve, we annex *fig. 612.* to explain by it the result of the experiments of Buffon, given in the second table. The ordinates of the polygon N, O, P, Q, &c. represent the results of the experiments made upon beams 5.330 in. square, of different lengths, whose primitive strength varied in each piece.

1617. The ordinates of the regular curve, *m, l, i, h, g, f, e, d, c, b, Z,* show the results of the calculation according to the rule, taking the same primitive strength for each piece.

1618. After what has been said in a preceding page, it is easy to conceive that the primitive unequal strengths would form an irregular polygon, whereof each point would answer to a different curve; whilst, supposing the same primitive strength to belong to each piece, there should be an agreement between the strengths and scantlings which constitute a regular curve.

1619. Thus it is to be observed that the points O and P of the regular polygon only vary from the regular curve, *m, l, k, i,* &c., because the ordinate LO is the product of a primitive strength diminished by the mean primitive strength which produced the ordinate of the curve KP. Hence the point P is above the properly correspondent point *k.*

1620. For the same reason, the point *c* is above its corresponding point X, because the relative ordinate Cc is the product of a primitive strength greater than the mean which produced the point X.

Fig. 612.

1621. Referring to the second table, we find that the primitive strength answering to the point O is but 60·76, and the value of the ordinate LO 2502, whilst that of the point P is 68·34, and the value of the ordinate KP 3364; and as the ordinates Ll and Kk corresponding to the curve are calculated upon the same primitive strength of 64·36, which for Ll gives 2726, and for KP 3092: it follows that, in considering all these quantities as equal parts of a similar scale, the point P of the polygon should be  $(3364 - 3092 =)$  272 of these parts above the corresponding point k of the curve, and the point O 224 of those parts  $(2726 - 2502)$  below the point l.

1622. To render the researches made, available and useful, the table which follows has been calculated so as to exhibit the greatest strength of beams from pieces 3·198 in. square, up to 19·188 in. by 26·65 in.

The first column contains the length of each piece in English feet.

The second column, the proportion of the depth to the length; and

The third, the greatest strength of each piece in pounds averdupois.

The table is for oak; and it is to be recollected that the weight is supposed to be concentrated in the middle of the bearing of the beams, and hence double what it would be if distributed over the whole length of each piece.

Experience, as well as investigation of the experiments, shows, that in order to resist all the efforts and strains which, in practice, timber has to encounter, the weight with which it is loaded ought to be very much less than its breaking weight, and that it ought not to be more than one tenth of what is given as the breaking weight in the following table, beyond which it would not be safe to trust it. The abstraction of the last figure on the right hand, therefore, gives the practicable strength by simple inspection. In a subsequent page, the reduction of the strength of oak to fir, which is in more general use in this country, will be introduced, so as to make the table of more general utility.

TABLE VI.

Showing the greatest Strength of Oak Timber lying horizontally, in pounds averdupois.
